De Beauvoir accepts that biology plays an important part in one's identity (we live our bodies), but argues that it cannot be used to determine one's destiny. Women's role in reproduction has caused her to be exclusively identified with this role, but with adequate social changes such as childcare and medical advances, there is no reason why reproduction should limit a woman's capacity for freedom. The problem with a biological account of sexual difference, she argues, is that it may attribute essences to men and women, splitting human beings into two types or essential identities.[24] There may be perceptible differences (in physical strength for example), but there is no intrinsic reason why strength should be given a superior value. Such values depend on social context, and are therefore open to revision.

De Beauvoir may wish to dissociate herself from the 'biology is destiny' position, but she often seems to come close to rejecting biology altogether. If women are restrictively defined as 'mere' bodies or as mothers then such restrictions must be overcome, to ensure that women are able to realize their choices consciously. But de Beauvoir does not always consider the extent to which she may be echoing a misogynistic distaste for the female body in trying to overturn such determinations. 'It has been well said that women have "infirmity in the abdomen", and it is true that they have within them a hostile element—it is the species gnawing at their vitals.'[25]

These aspects of her argument are an attempt to escape from essentialism or biologism and to affirm the demand for self-determination. But de Beauvoir has also argued that women's own experience is important and should be validated, even if such experience is of a less independent nature than men's. After sex, she suggests, men are free to take up their individuality once again, whereas women feel themselves to be more 'connected' to biology and more embodied, with responsibility for reproduction within themselves—an experience of their own 'immanence'.[26] De Beauvoir's commitment to projects of transcendence and freedom on the one hand, and her argument that women are more immanently 'in' their bodies on the other, seems to suggest that women are placed in the impossible position of having to transcend their own bodies. It suggests that if women do not seektranscendence they are 'inauthentic' or guilty of bad faith, but if they do seek transcendence it will be a project of self-defeat, an attempt to escape from the immanent realm which is 'feminine'.[27] This contradiction has led some feminists to interpret de Beauvoir either as essentialist or as suggesting that sexual identity is culturally constructed. In fact she seems to be in both positions, and the tension here can be

interpreted as part of the contradictions in her existentialist framework.

In keeping with her initial socialist perspective on oppression, de Beauvoir does seem to locate inequalities between the sexes in a social or cultural context. Such declarations as 'One is not born a woman, one becomes one'[28] or 'the body is not a thing, it is a situation'[29] would tend to support this interpretation. Her concern is to ensure that inequalities can be diagnosed, and so combated, at this level. She refuses to accept that any biological or essentialist reason could be given to prevent women overcoming their 'secondary' position. Sheer effort of will, the widespread recognition of women's freedom and choices (which must also be recognized by men) and the fuller availability of choices will bring about greater equality of the sexes. This uncompromising stance often leads her to be stern about the efforts women must make to transcend determination for themselves, in effect to 'stop colluding' in becoming the other for men. Her objective is to galvanize women into asserting their autonomy and formulating projects which will allow them to develop their own identity. She has been criticized for apparently suggesting that it is only if women become more like men that equality will be attained, partly because the kinds of projects she values as important are derived from a framework which itself could still be described as masculine—emphasizing fewer domestic ties, the need for recognized (and paid) labour, perhaps specifically the work of individual creative artists. However, she does suggest that even complete equality in this sphere would not cancel out all differences between the sexes, and women would still maintain a specific understanding of their own sexuality.[30]

AFTER DE BEAUVOIR

The increasingly complex account of otherness that feminist theory in France has developed owes a clear debt to de Beauvoir's analysis of Woman as Other. Feminists have sought to combine the forceful political critique provided by drawing attention to sexual difference, with an analysis of identity drawn from developments in poststructuralist and psychoanalytic theory. Such an analysis draws attention to the self's vulnerability to the displacing effects of desire, as well as to the socially and culturally constructed nature of identity, implicating systems of language and meaning in such a critique.[31]

Rather than situating projects for change and emancipation within existing political and cultural practices, many feminists have subjected such practices to a sustained critique, asking questions about the very constitution of meaning and the concepts of power and politics as such. Whereas de Beauvoir stressed the strong will and self-control required in struggling for equality and autonomy, subsequent theories have raised questions about the very nature of equality and the extent to which such self-control can be practised. In this respect, feminist critiques of identity as rational or masculine coincide with psychoanalytic theory regarding the displacement of consciousness by forces which call into question the epistemological privilege of the subject. Such forces are seen as all-pervasive and unsettling, manifest in systems of representation and language and are understood as corresponding linguistically to the processes of desire. This theory, shaped in part by Lacan's work in structuralism and psychoanalysis, looks at difference as a

relation operating not only intersubjectively between self and other, but also as sets of relations of differences within the very systems of signification which order and create meaning. This expanded version of difference means that apparently unified or singular terms are seen to operate by processes of exclusion or suppression, occluding their relation to, or reliance upon, other terms. Discrete or autonomous identities are shown to be disrupted or undermined by 'otherness' and concepts such as 'truth' or 'knowledge' are put into question.

Hence the maintenance of identity as rational and autonomous and the notion of truth as objective and independent are viewed as a defence of territory by the exclusion of that which is other. Anything which lies outside the 'normal' circuits of knowledge or identity gets classified as madness, chaos, darkness or ignorance, and the borders between the two realms are characterized as the site of constant power struggles. Many thinkers also draw attention to a symbolic equation between the excluded otherness and the feminine. Whether this connection is made explicitly or implicitly, the feminine as otherness is seen as multiple, dissembling and excluded, yet capable of disrupting limits and disturbing the status quo.

Thus a connection is established between sexual difference (male/ female or masculine/feminine) and polarized oppositions such as self/ other, knowledge/ignorance, spirit/body. De Beauvoir makes it possible to draw these parallels from a feminist viewpoint, and to politicize the hierarchical arrangement of such oppositions. Apparent neutrality is thus opened up for analysis as an imbalance of power. But de Beauvoir retains her existentialist/humanist framework when discussing a possible feminist practice, whereas other feminist thinkers take up thecritique of the humanist subject as besieged and intersected by unruly forces of desire and structures of power. Thinkers such as Julia Kristeva, Hélène Cixous or Luce Irigaray are influenced by understandings of otherness inherited from Hegel, Sartre and Heidegger, as well as by Derrida's account of western thinking as phallo-logo-centric, unduly centred on a particular account of truth which is infused with masculine values, and Foucault's analyses of the connections between power and knowledge. They are also influenced by Lacanian theory concerning sexuality, language and identity.[32]

Psychoanalytic theory has proved useful to feminist theory, in that it can show the extent to which identity and sexuality are constructed by conflicting and quasi-deterministic forces, as well as indicating the penetration of such forces to psychic structures.[33] At the same time there is an acknowledgement of the implicitly sexual nature of structures and economies which are ostensibly neutral. Hence on one level it provides a generalizable account of identity construction, cross-culturally and trans-historically. Despite the danger of universalizing identity which such an analysis courts, it does give a certain force to the analysis of sexual difference: the dominant structures which divide sexuality into two essential types may need to be challenged and addressed at precisely this level. However, the determinism implied by such internalized constructions is offset somewhat by the notion of the unconscious. The unconscious can act as a constant reminder of the overall failure of the internalization process: 'a resistance to identity at the very heart of psychic life',[34] as Jacqueline Rose puts it. The splits, forcings and divisions of psychic life place pressure against the notion of coherent identity, a widespread replay of an incomplete adjustment to the norm. This moment of

failure, negativity, fluidity or formlessness is symbolically bound up with the feminine. As Rose suggests, feminists may recognize certain similarities with their own projects—a 'symbolic failure to adjust to normality'[35] and the resistance this implies.

Lacan suggests that the whole social and cultural context of meaning, the Symbolic Order, is premised on a suppression or repression of the symbolically feminine/maternal. Symbolically otherness stands as excessive, ex-centric and ecstatic, beyond or outside the dominant order of meanings, which allows Lacan to state 'the woman does not exist'.[36] Whether this is the pre-Oedipal mother or the quintessentially feminine, the Ideal woman or the dark absence of negativity, it is the process by which such a realm is designated as Other or otherness which allows the dominant meanings to retain their hold on truth, singularity and power, although paradoxically such otherness is the hidden ground or unacknowledged axis of such an economy.

In its very construction the Lacanian framework is emphatically unfeminist. Nevertheless, Lacan accords women, or the feminine, a kind of power, the possibility of disrupting signifying systems, albeit without the agency to do anything other than constantly disrupt, efface, move on. 'I believe in the jouissance of the woman in so far as it is something more, on condition that you screen off that *something more* until I have properly explained it.'[37] The force of feminist theory influenced by Lacan may be understood as a kind of 'return of the repressed'.[38] The unnameable and unrepresentable feminine jouissance Lacan has proscribed is taken up as the power of disruption and destabilization, and works to unsettle fixation, particularly in the realm of sexual stereotypes.

JULIA KRISTEVA

The interdisciplinary nature of Julia Kristeva's work, drawing from linguistic theory, Marxism, philosophy and psychoanalysis, makes her a versatile and wide-ranging thinker. She sees herself as a cultural critic and analyst rather than particularly as a feminist thinker, although many feminists see potentials in her work for developing critiques of western thinking and for understanding problems of identity, and she certainly deals with questions about 'the feminine', cultural representations of figures such as 'the mother', or topics such as Chinese women. Coming to Paris from Bulgaria in the mid-1960s, she brought with her a mixture of left-wing politics and an approach to literary criticism influenced by Russian formalism: in brief, a materialist approach to signification and social structures, tempered by her commitment to aesthetic and cultural practices and her desire to change oppressive conditions.[39] The common themes running through her work are an interest in language, politics and sexual identity, themes initially broached in her doctoral thesis *Revolution in Poetic Language* (1974),[40] where she attempts to develop a theory of identity formation in the context of Lacanian psychoanalysis and structuralism. Her main concern in this book is to understand the structuring effects of language without relinquishing the creative, poetic and marginal aspects. She then links her theory to a political account of marginalized but revolutionary forces, exemplified in the figure of the avant-garde poet.

Through a complex intersection of theoretical perspectives, Kristeva develops her

account of the material/linguistic forces which constantly disrupt identity, but are still located within the corporeal body. She suggests that identity is forged in a precarious and dynamic relation between various positionalities which can be taken up according to the social and cultural meanings in the Symbolic, and a force of negativity which is persistently engaged in undermining such positions. Her analysis has proved intriguing for many feminist theorists for a number ofreasons. First, she emphasizes the critique of identity as a fixed or essential notion. Second, she identifies the constructed nature of meaning and sexuality, and the determining or restrictive effect which existing definitions, stereotypes and cultural roles can have in shaping identity. Third, she identifies a transgressive force which, if activated, can have a disruptive or revolutionizing effect on the social/cultural context in question. Her account of 'the subject-in-process'[41] analyses the cost involved in subject formation, but it also hints at ways of subverting the dominant forms of understanding sexual difference. For feminist theorists, she seems to negotiate essentialism on the one hand by suggesting that subject 'positions' are being created and destroyed in the ongoing dialectic of signification, and yet she refuses to diffuse subjectivity into merely an effect of language.

For Kristeva, Lacan's 'return to Freud' (his reworking of Freud)[42] is important in that it shifts the focus from biology to a linguistic shaping of sexuality and identity. This shift, she thinks, will allow for a different way of understanding identity. If sexual difference is implicated in the conceptual framework itself, Kristeva's characterization of language as a shifting process of the production and decay of meaning allows her a potential for mobility on the question of identity formation. The Freudian focus on a visible/biological structure seems very limiting in the light of the fluid freeing of sexual difference into the Symbolic arena (many potential positionalities or social roles to be fulfilled). But in some ways all that has happened is a shifting of the terms of formation. Lacan's point that a framework of cultural reference is the only place from which any account of sexual difference can be produced, is meant to negate any simplistic biological starting point. Now that difference is seen as being produced by systems of meaning, there is no direct access to a pure biological understanding of physical bodies, since it would be impossible to recognize such bodies outside of the system of meaning. This is the basis of the development of the imaginary, the realm which severs full cognisance of the body and renders its relation metaphorical or 'morphological'. If identity is seen as *structuration* rather than as psycho-physical development through time, the issue shifts from questions of anatomical difference (at what point in development do differences appear?) to questions as to what such differences *mean* within the symbolic, and the extent to which they are open to subversion. But because Lacan denies any access to an 'other' realm, for him there can only be the conceptions of sexual difference which already exist, but which are inherently 'masculine' (because created in the Symbolic).[43]

For Lacan, the primary relation with the mother's body, which he had characterized as fluid and plural, the realm of unmediated jouissance, was what had to be overcome so that identity could be established. Successfully relinquishing this realm of non-separation allows for successful entry into the Symbolic and identification with the masculine or patriarchal values of social/cultural meaning. The price to be paid for attaining linguistic competence and a place in the Symbolic is the loss of the blissful, unselfconscious pleasure before the entry into language. However, Kristeva argues that the overcoming of

this 'other' realm can never be wholly successful, and it will continue to break through or irrupt into the Symbolic Order, where its effects will be felt bodily as pleasurable disturbances. Symbolically, such disruptions will connote the pre-Oedipal and the feminine.

The focus of Kristeva's work on femininity is governed by this understanding. If the structuration of identity is at the level of language, but this process is constantly invaded by the 'language' of the other realm, then its stability is called into question. Perhaps by insisting upon the disruptive rather than the constitutive elements of language, a sufficiently transgressive notion of the subject can be produced to allow it to reformulate itself, 'more or less' masculine or feminine?

Kristeva is critical of theorists who focus on language as a homogeneous, logical system with internal coherence. It would seem she has in mind the prioritizing of communication, consensus and competence she finds in the work of Saussure and Chomsky and in Lacan's symbolic. In contrast, Kristeva focuses on the 'edges' of language, the points at which language appears to break down: the 'pathologies' of madness and schizophrenia, the hermetic and difficult poetries of the avant-garde, and the 'hysteria' of women. She theorizes these aspects in a different way from other linguists, who had seen these forms of language as continuous with conventional signification, but less successful. If the formal practice of language uses is emphasized, these deviant practices are judged according to their conformity or deliberate flouting of the rules. Structuralist linguists minimized reference to 'subjective' elements. Kristeva seeks to identify a connection, but, as she makes clear, it is a productive and dynamic relation she is interested in, not a relation of stasis or a revival of a humanist subject.

Focusing on rhythm, repetition, elision and displacement reinforces a notion of the subject-in-process, rather than an ideal enunciator, since it concerns the apparent failures rather than the successes of the struggle to maintain a coherent identity. It is also indicating the points at which the 'other' realm is discernible through its effects.

Kristeva's notions of 'the semiotic' and the *'chora'* present an attempt to theorize this untheorizable, pre-discursive realm which is described in terms of 'space' or a locus to avoid pinning it to a stage of development. She writes of the semiotic as a kind of primordial writing or signifying of the body, although this is not strictly an accurate description, since it is concerned with 'the body of a subject who is not yet constituted as such'.[44] Still, this pre-signifying signification is a textuality of the body which is more experiential than meaningful. 'We understand the term semiotic in its Greek sense; σημεῖσν=distinctive mark, trace, index, precursory sign, proof engraved or written sign, imprint, trace, figuration.'[45] It is an ordering of energies which initiates the inscription and conditions for representation. Hypothesized as both the material rhythms and forces underlying the possibility of textuality, and the imprinting of psychical energies to connect sensation to movement, it acts as a preparation for entry into language. This space is as yet undifferentiated but it cannot be described as homogeneous, shot through with 'psychical marks' and in a state of motility. Kristeva names it as 'the *chora*…an essentially mobile and extremely provisional articulation constituted by movements and their ephemeral stases'.[46]

That this notion is positioned 'prior' to signification should not be taken to indicate a necessary chronology in time, since this realm is symbolically 'other' to temporal order

as well as topographical space. Therefore although it is given an apparently archaic and originary status, it does not constitute a reified origin divided from the subject in the symbolic. This would replicate a duality which Kristeva is concerned to resist; the terms are not equal and the notion of origin is reconstructed only in retrospect from positions already in language. In fact, Kristeva is explicitly critical of Lacan for making the repression of the mother the condition of subjectivity. As she draws attention to the symbolic connection of the *chora* with feminine or maternal notions, she is taking up pre-figured connections which identify the notion of an origin with a primordial mother: 'This place which has no thesis and no position, the process by which significance is constituted. Plato himself leads us to such a process when he call this receptacle or chora nourishing or maternal.'[47] However, the semiotic is in one important sense opposed to the Symbolic: it is a site of resistance and disruption against which the organization of the Symbolic is to be compared. Kristeva takes up the equation of otherness with the feminine or maternal, in order to demonstrate the sacrificial process involved in identity construction, and to suggest how the inherent violence might be made less painful or channelled in more creative ways.

Despite the alignment of otherness and the feminine, for Kristeva it does not constitute an alternative identity for women, nor does it allow a specifically female or feminine language. However, there are ways of maximizing its disruptive effects in order to combat the restrictive impact of the Symbolic. The figures of the avant-garde poet and the political dissident are focal points in Kristeva's earlier work, while later on she considers women as potential disruptive figures.

> What the father doesn't say about the unconscious, what sign and time repress in their impulses, appears as their *truth* (if there is no absolute, what is truth, if not the unspoken of the spoken?) and this truth can be imagined only as a woman. A curious truth: outside time, with neither past nor future, neither true nor false; buried underground, it neither postulates nor judges. It refuses, displaces, breaks the symbolic order before it can re-establish itself.[48]

Kristeva suggests three ways in which this curious truth may be understood: 'Jouissance, pregnancy, and marginal speech: the means by which this "truth", cloaked and hidden by the symbolic order and its companion, time, functions through women'.[49] Here Kristeva is linking 'a vigilance, call it ethical',[50] with the figuration of the feminine and the maternal as 'other'. It is a critical and disruptive kind of ethicality, linked to a capacity to resist the fixation of subjectivity and to remain critical, but also seeking a means to express such 'otherness'.

> To refuse all roles, in order, on the contrary, to summon this timeless 'truth'—formless, neither true nor false, echo of our jouissance, of our madness, of our pregnancies—into the order of speech and social symbolism. But how? By listening; by recognising the unspoken in speech; by calling attention at all times to whatever remains unsatisfied, repressed, new, eccentric, incomprehensible, disturbing the status quo.[51]

Here she seems to be suggesting that the location of ethicality is no longer adequately situated in the reformulation and attempted perfection of codes of behaviour, rules and laws. Unless the disruptive traces of the subject, constantly being rewritten in its processes, can also be accounted for, these projects are destined to keep retreading the same ground. The constant transgression and renewal of positioning in relation to the process of signification leads to the possibility of new practices, forged at the very boundaries of thinking.

Kristeva finds in maternity the metaphoric expression of the above boundary location of ethicality, which is given the force of subversion but still embodied. Maternity connotes a possible irruption and interruption of the Symbolic, centrally placed, yet disruptive, a disturbance between stasis and dynamism, cyclical/monumental time and discursive/grammatical time. In her essay 'Stabat Mater',[52] the poetic, left-hand (sinister?) 'other' side of the text irrupts into the historical and chronological mapping of motherhood. Textually this corresponds to a writing of the metaphoric mother, positioned as a body in signification and yet already split, separated, pleasuring; 'the heterogeneity not subsumed under any law'. A space is opened for different subjective possibilities, yet retaining the specificity of women. This 'heretical ethics' (her-ethics) is based not upon avoiding the law, but upon enriching it. 'Now, if a contemporary ethics is no longer seen as being the same as morality; if ethics amounts to not avoiding the embarrassing and inevitable problematics of the law but giving it flesh, language, jouissance—in that case its reformulation demands the contribution of women.'[53] A similar position is taken in Kristeva's analysis of the role of the Virgin Mary. In 'Stabat Mater' she draws heavily upon Marina Warner's book *Alone of All Her Sex; the Myth and Cult of the Virgin Mary*[54] to indicate how the Virgin Mary becomes a symbolic axis of the conjunction between hebraic and hellenic; and as a conjunction between virginity and maternity. As a moment of undecidability, the figure presents a potential site of ambivalence, for the two traditions as well as for understandings of women. There is a potential disruption of the Greek logos and Jewish monotheism in the presence of a divine feminine figure, central to religion but neither one thing nor another. But this dangerous ambivalence is conscripted for control and synthesis, in that the virginal aspect becomes a pure and holy asceticism, and maternity becomes the continuity of the community via reproduction. The freezing of undecidability sets up an ideal, fusing with the existing ideal of virginity in courtly love and the ideal of devoted maternal love. The impossible totality of the virgin mother is not only disseminated within patriarchal cultures but becomes the prototype for western love relations. In Kristeva's terms, the dangerous moment of rupture is contained by erasing jouissance, in virginity, and channelling it, in maternal reproduction, to sustain the deathless ideal of the masculine, whether this is the law, the community or the subject.

This maternal figure, the epitome of romantic sentimentality and utterly serene icon, ideal and untroubled, functions as a sublimating vessel for various cultures. And yet Kristeva indicates that its 'cleverly balanced architecture today appears to be crumbling', the 'psychotic sore of modernity' is 'the incapacity of contemporary codes to tame the maternal'.[55] Thus it reveals that which it cannot contain even in trying to cover over this slippage.

Despite Kristeva's characterization of the subject as 'an open system', I don't think she

is committed to the denial of sexual difference or the 'erasure' of the subject. However, she does argue that the positionality which may lead to a metaphysical hypostatization of identity is to be found in feminist discourse too. This is perhaps what leads her to be unnecessarily harsh on the variety of feminist positions which do not coincide with her own; a fear of the reintroduction of the essentialist subject which has led women to 'sacrifice or violence'. If this is a challenge to feminist theory, is it the kind of critique which feminist theory needs? Many feminist writers on Kristeva find her attacks on feminism uncomfortable, especially when they seem to emanate from an apparently powerful position as the 'queen of theory'. But on occasion her work is compatible with feminist approaches to the body, offering a potential rethinking of corporeality in keeping with a radical perspective on difference. As Rosi Braidotti puts it:

> the body thus defined cannot be reduced to the biological, nor can it be confined to social conditioning. In a new form of 'corporeal materialism', the body is seen as an inter-face, a threshold, a field of intersection of material and symbolic forces; it is a surface where multiple codes of power and knowledge are inscribed; it is a construction that transforms and capitalises on energies of a heteronomous and discontinuous nature. The body is not an essence, and therefore not an anatomical destiny.[56]

LUCE IRIGARAY

Like Kristeva, Irigaray has a background in linguistics, psychoanalysis, philosophy and feminist theory, and is currently practising therapy or analysis. However, she takes a set of premises very different from Kristeva's from these areas, and produces markedly different conclusions.

Born in 1930 in Belgium, Luce Irigaray began her work with research into psycholinguistics, specifically the language of patients diagnosed schizophrenic or suffering from senile dementia (see some of the essays in *Speaking/Language is Never Neutral/Neuter* first published in 1986).[57] Her conclusions concerning the loss or lack of identity of such patients who seem 'overwhelmed' by language led her to draw comparisons with the position of women in relation to language. In the process of the analytic session, understood as a dialogue between two speakers, Irigaray noted a number of factors which continue to be important throughout her work. First, the emergence of identity formulated as possible positions in such locutionary exchanges. Second, the differences (specifically sexual difference) dramatized or enacted in speech. Third, the points at which grammatical formulations of language begin to break down, and the experience of speakers caught in this position. Her focus is the vulnerability of subjectivity and the attempts to secure a place for it against the destructive technologization of communication in the present age. However, her concern is not the resurrection of a humanist subject but a critique of the language and thinking which presents itself as neutral or neuter.

Irigaray combines this research with her understanding of Lacanian psychoanalysis and structuralism concerning the construction of identity, to throw light on what she sees as a

sacrificial culture and the position of women in such a culture. One of her concerns, which has been extensively misinterpreted, is her attempt to develop an alternative strategy to allow 'feminine identity' to take (a) place. Although she has often been understood to be positing a language of the female body, the level of her intervention is markedly that of cultural and social formations. She does suggest that the dominant form of discourse has been 'isomorphic' with masculine sexuality, and it is this relation which has been difficult to understand or translate. It is not simply a representational model but a relation itself to be understood as metaphoric or metonymic. If this relation has dominated in the past, perhaps there could be a form of discourse which has morphological suggestions of images of the female body? It is this 'hypothetical' style she deploys in the essay *This Sex Which is Not One*' (first published in 1977),[58] and which has led to the assumption that she is 'writing the body'. Rather, it appears that this stylistic deployment is a strategic intervention in what she feels has been a monologic or 'phallo-logo-centric' approach to questions of sexuality and language. In her later work it appears that she is concerned more with existing social formations and linguistic practices than with developing a completely alternative female language, and her recent empirical studies into language use and sexual difference would seem, with hindsight, to support this analysis of her early writings. However, this does not lessen her attempts to restore, or rather to create, a less damaged and damaging understanding of sexual difference.

At the beginning of her book *The Ethics of Sexual Difference,* (first published in 1984),[59] she states her belief that sexual difference is the burning issue of our age, the issue of difference which potentially could be 'our salvation on an intellectual level…the production of a new age of thought, art, poetry and language; the creation of a new *poetics*'. However, she suggests that the development of this event is hampered and constrained by the systematic repetition of sameness being compulsively reiterated in the spheres of philosophy, politics, religion and science. This repetition, or reworking of the same ground, is evident in many contexts, which Irigaray lists as 'the consumer society, the circular nature of discourse, the more or less cancerous diseases of our age, the unreliable nature of words, the end of philosophy, religious despair or the regressive return to religion, scientistic imperialism or a technique that does not take the human subject into account, and so on'.[60] According to Irigaray, this repetition works to conceal or efface a possible way of articulating otherness. This articulation, she thinks, can best take place in the context of questions of sexual difference. Apart from the explicit feminist perspective, her reasons for privileging sexual difference lie in her specific appropriation of psychoanalytic discourse, particularly the work of Lacan. Despite her use of a psychoanalytic framework, her work is also a strategic departure from it, or an attempt to subvert it from within. She suggests that psychoanalysis has enabled a theoretical treatment of sexuality and identity to take place via the (generalizable) analysis of forms of patriarchal identity as constructions. Her focus on the *constructed* nature of such notions as identity, philosophical discourse and its concepts has a number of implications. She is able to diagnose a bias running through the history of such notions and to point to the permeation of such forces to psychic levels. She is also able to conduct a sustained critique of the damaging nature of such constructions as exclusion or suppression. She thus sees her work as 'jamming the machinery'[61] of western theory, a

process of analysing and uncovering the fantasies, projections and repressions which are taken to be normal or necessary. The nature of this work is extensive and radical.

> For the work of sexual difference to take place, a revolution in thought and ethics is needed. We must re-interpret the whole relationship between the subject and discourse, the subject and the world, the subject and the cosmic, the microcosmic and the macrocosmic…. In order to think and live through this difference, we must reconsider the whole question of space and time.[62]

If such apparently foundational notions are shown to be constructions, then there is a possibility that they may be modified or changed in the future. For Irigaray, the usefulness of psychoanalytic theory rests in some part on its capacity to analyse the symbolism of masculine and feminine as a pair of terms which pervade wide and various sets of relations, such that the symbolization becomes tangled up in the very process of conceptualization. The common oppositions of the Pythagorean table of opposites become aligned with a symbolic interpretation of anatomical difference, and, significantly, the unified, non-contradictory and homogenous terms come to dominate. Across a range of systems and at different levels, exclusion and censorship operate to prioritize the masculine term at the expense of the feminine, such that the very operation itself is obscured from view. The status quo is maintained at the price of a peculiar violence—the exclusion of the feminine, or its characterization as object, matter, inferior term. As regards subjectivity, masculine/feminine forces or values may become aligned with male and female sexes, but, she suggests, the very notion of subjectivity itself has 'already been appropriated to the masculine', despite the way that such a notion is presented as neutral. It is because such structures are built upon repression and denial that inevitably the tension of maintaining such a territory begins to show and the cracks, failures and breakdowns indicate the spaces through which the potentiality of the feminine may begin to be built. It is through her under-standing and seizure of a certain *lack* of synchronization, therefore, that Irigaray situates her project.

Irigaray's engagement with philosophy has been extensive. If she sees philosophical discourse as 'the master discourse…the discourse on discourses'[63]—adding, 'the philosophical order is indeed the one that has to be questioned, and disturbed, inasmuch as it covers over sexual difference[64]—she has also identified philosophy's resources as crucial in reinterpreting questions of sexual difference. She sees her focus as philosophical, but her work is a dramatic testimony to the ambivalence she feels as a woman in philosophy, and as such displays an equivocation between her critique of philosophy and her more positive reconstructions of female subjectivity.

In the context of philosophy, she announces her desire to 'have a fling with the philosophers',[65] paradoxically to indicate the seriousness of her engagement with philosophical questions. This means 'going back through the male imaginary', and gives rise to 'the necessity of "reopening" the figures of philosophical discourse—idea, substance, subject, transcendental subjectivity, absolute knowledge—in order to pry out of them what they have borrowed that is feminine, from the feminine, to make them "render up" and give back what they owe the feminine.'[66]

She means to be as intimate and familiar with philosophical history as possible, but

also to challenge it from the position of a woman; that is, one who is symbolically positioned outside or other to philosophy, one who can only 'flirt' with ideas, or conversely, deflate them by being too playful, refusing to take them seriously. This positioning allows Irigaray to follow through some of the main canonical texts of western philosophy; in *Speculum of the Other Woman* (first published in 1974), she takes on Plato, Aristotle, Meister Eckhart, Descartes, Hegel, Spinoza, Plotinus, Kant, Marx, Freud, and in *The Ethics of Sexual Difference* she adds Hegel, Merleau-Ponty and Levinas, while other texts deal with Nietzsche and Heidegger, for example,[67] reconstructing their logic carefully in order to show how it interrupts itself. What she calls 'the blind spot in an old dream of symmetry',[68] the hidden assumption so necessary to the symmetry and so necessarily hidden, will entail analysing philosophy's unconscious.

For Irigaray, what is repressed is 'the feminine', that which allows philosophy to get off the ground, but must remain essentially unspoken, as the ground. The negativity of symbolically occupying this groundless ground constantly places women in an impossible position. As primal matter or 'mother-matter', the feminine or maternal acts an archaic past, the 'nature' placed in opposition to culture. 'The mother-woman remains the place separated from its "own place", a place deprived of a place of its own. She is, or ceaselessly becomes, the place of the other who cannot separate himself from it.'[69] One of Irigaray's concerns is to explore the suppressed or superseded nature of this element or 'the elemental' space, partly to remind philosophy of its debt to this unexplored 'pre-rational' world-view and partly to try to develop a vocabulary which could articulate this otherness. Irigaray writes: 'I wanted to go back to this natural material which makes up our bodies, in which our lives and our environment are grounded; the flesh of our passions.'[70] Her 'elemental' texts deal with air, earth, water and fire, her 're-invention' of the material origins of philosophical thinking and its elision with maternal or feminine symbolism (for example in *Marine Lover of Friedrich Nietzsche* (first published in 1980) she shows a certain aversion in Nietzsche's writing to water, which is symbolically feminine). In trying to imagine this 'other region' she employs a strategic syntactical style, an interplay of weaving in the writing of the body as she had expressed it—multiplicity and plurality, with frequent changes of tense, and questions disurpting her work and interrupting whichever position she was speaking from. Speaking (as) woman is a tactical means of restoring specificity to a non-specific discourse, and also corresponds to her aim to put the philosophical subject back into a material context—the body and the materiality of its surroundings.

Irigaray's strategy in reading these canonical texts is to imitate their movements, a mimicry which is, in its very exaggerated miming, in excess of the limits and definitions which had been set.

> There is in an initial phase, perhaps only one 'path', the one historically assigned to the feminine: that of mimicry. One must assume the feminine role deliberately. Which means already to convert a form of subordination into an affirmation and thus to begin to thwart it.… To play with mimesis is thus, for a woman, to try to recover the place of her exploitation by discourse, without allowing herself to be simply reduced to it.[71]

Her strategy of mimicry is directly related to the notion of 'mirroring' which runs throughout her texts. This notion is part of a complex set of interwoven strands which explore the preoccupation of western thinking with accurate 'reflection', illumination, and clarity. Not only do metaphors of the 'ocular' and 'specular' seem to dominate, but, she suggests, they are essential for the establishing of the self-reflexive subject, and the apparent autonomy of the philosopher. The narcissism of the subject that results is, for Irigaray, part of the logic of 'the same'. However, she also suggests that the speculations which privilege this version of the epistemological subject are based upon a (hidden) reliance upon women or the feminine to act as a mirror for such a subject, at the expense of their own identity. Women are either frozeninto static representations dictated by the logic of the same, or they are positioned wholly outside the system as a conceptual 'black hole'; the elsewhere and otherwise without a status of its own. In *Speculum* Irigaray suggests equivalencies with Freud's dark continent or Plato's cave, the exploration of which is deemed essential and yet produces, according to Irigaray, theory still caught within its own expectations, more of the same. In order to broach the question of sexual difference, Irigaray produces a critique of the 'flat mirror' of 'the processes of specula (riza)tion that subtend our social and cultural organisations'[72] and suggests, through such a critique, another mode of approach which will allow for feminine subjectivity: '*a curved mirror,* but also one that is *folded back on itself,* with its impossible appropriation "on the inside" of the mind, of thought, of subjectivity. Whence the *intervention of the speculum and the concave mirror,* which disturb the staging of representation.'[73] If mimesis is no longer direct and accurate 'reflection', then the distorting mirror in which women have been confined can throw back 'disturbed' and disturbing reflections, thereby beginning the process of allowing the feminine to take (a) place. This is a mimicry which not only twists and parodies, but effects a change in the process.

Irigaray proposes a particular conception of psychic health to counteract the crisis and fragmentation of the present age, which would involve the adequate conceptualization of both masculine and feminine elements in a non-hierarchical exchange and process. However, we are far from this stage. The feminine is still inadequately conceptualized. It is only by intervening on the destructive circuit that another age of difference might be broached, an intervention which Irigaray describes as ethical. The revaluation of 'passion' and 'wonder' *(admiration)*[74] could lead to relations which, while retaining the radical otherness of the other, allow for an ethical encounter to take place.

Irigaray's more explicitly political proposals include interventions in the legal, civil and representional status of women[75] and her own work with various women's groups in Italy for example. But she has also explored more 'mystical' approaches; lyrical poetic expressions of love between women, between mothers and daughters and lovers, and her work on 'the divine', which is an attempt to explore the forms of sacred meaning which have also acted to exclude women, and to revalue divisions between sacred/profane, carnal/celestial, matter/spirit.[76]

Irigaray's equivocations may strike her critics as contradictory or difficult to place. How are we to understand what seem to be utopic projections of 'amatory exchanges' and a new fertile dialogue of sexual difference in the light of her sustained critique of subjectivity and philosophy, the 'sacrificial culture'? Is she writing for all women? From where? However, at present she is perceived to be a thinker who manages to negotiate the

minefields and sustain the tensions with acuity, a position which itself invites further responses and engagements with her writings.[77]

MICHÈLE LE DOEUFF

Michèle Le Doeuff was born in 1948, taught philosophy at the Ecole Normale Supérieure and is currently doing research at the CRNS. Her focus on the apparently innocuous illustrative devices used in philosophy (and she shows that 'the feminine' is a constantly recurring item) uncovers a tension at the heart of such texts which has repercussions for women's relation to philosophy. Although metaphors and images may appear to be harmless, especially when they are explicitly given a secondary status, one of Le Doeuff's concerns is to expose such an assumption. Her reading of the history of philosophy shows how philosophy draws upon a very specific set of such devices which function in quite particular ways in the texts, even as 'philosophical discourse…labels itself as philosophical by means of a deviation from the mythic, the poetic and all that is image making'.[78] For Le Doeuff, these images point to tensions or stress lines in the organization of the philosophical enterprise, the 'sensitive nerve endings' which say more about philosophical discourse than it would prefer to speak. For not only do they provide continuity markers in the history of philosophy, but they also indicate the 'obsessions, neuroses and dangers', or the more uncontrollable elements intrinsically bound up in the progress of reason. In her book *The Philosophical Imaginary* (first published in 1986) she analyses such images and figures in Kant, Rousseau, Plato, Moore, Bacon and Descartes. She argues that philosophy sets up the feminine as an internal enemy: 'a hostile principle, all the more hostile because there is no question of dispensing with it…the feminine, a support and signifier of something that, having been engendered by philosophy whilst being rejected by it, operates within as an indispensable deadweight'.[79]

Despite the psychoanalytic tones of this analysis, Le Doeuff rejects any notion of the unconscious at work. For her, the metaphors of 'the feminine' are expressed as part of the philosophical imaginary (which at times seems to resemble a bestiary), but she uses this term more in the sense of 'a collection of images' than in the sense which Lacan, or Irigaray, employ it. She argues that greater awareness of this process will have certain implications for changes in the practice of philosophy, but she rejects overarching frameworks such as Marxism or psychoanalysis, partly because of her concern that women in philosophy will exchange one set of orthodoxies for another, sitting at the feet of 'new masters' (Lacan and Derrick, amongst others), a process which sets up new forms of political correctness.

This is why she is careful to examine the specific relation of student and teacher in her more recent book *Hipparchia's Choice* (first published in *1989*).[80] She conducts an analysis of the way an apprenticeship is served in philosophy, considering what techniques of assessment, training and control are used. Seeing this relation in terms of influence and power or lack of it, she locates it within a wider set of relations, the relation of the academic institution to the particular social setting and historical inheritance, with connections between knowledge and power being made in a manner reminiscent of Foucault. Her 'case study' for this analysis is the relationship between Sartre and Simone

de Beauvoir, a complex site of tensions between male/female, teacher/ disciple (de Beauvoir's own description), philosophy/feminism.

Rather than concentrate upon the exclusion of women from philosophy, Le Doeuff emphasizes their incorporation into the very centre. Far from them appearing as victims of rigid expulsion, she points out, women have been philosophers all along, learning, corresponding, discussing and writing. However, the terms of their admission into philosophy have been, she suggests, quite strictly controlled, presenting a more complex and subtle picture of philosophy's process of self-legitimation.

Despite the cheerful optimism which Le Doeuff seems to display about the possibility of 'retraining' philosophy to be more open and tolerant, she doesn't underestimate the difficulties which such a demand presents. Rather, I would see her strategy as 'entrism', borrowing scholarly techniques in order to gain a legitimate foothold in philosophy, and from there developing the feminist challenges and provoking the changes which she believes the discipline must address. She wishes to redeem, restore and rehabilitate philosophy, arguing for a pluralistic 'contest of faculties', or 'constrained disagreement' in academia, which could allow for uncertainty and resisting closure, and prevent domination of any one viewpoint at the expense of other, more hesitant viewpoints. This approach, which Rosi Braidotti calls 'a reasoned critique of reason',[81] comparing it with the work of Lorraine Code or Genevieve Lloyd,[82] means that her work does not indict the whole of western philosophy for 'masculinism'. Her work is not really compatible with that of, for example, Irigaray's, because Le Doeuff does not subscribe to the discourse of radicality or revolution. Her 'commonsense' approach contrasts with the 'poetic-hysteric' style of other French feminists, but some critics find her occasionally too cautious.

HÉLÈNE CIXOUS

Hélène Cixous was born in Algeria in 1937, and has been professor of English literature at the University of Paris VIII at Vincennes, located in Saint-Denis, since 1968. It is with Cixous that the notion of *écriture féminine* (feminine, or female, writing) is most readily associated. Through her explorations of the relationship between sexuality and writing, mostly in her texts of the 1970s (which deliberately defy classification as poetry or theory), she tries to encourage the scripting of Lacan's forbidden feminine jouissance. While she seems to pay even less heed to the theoretical demands of philosophical rigour and clarity than Kristeva and Irigaray, she elaborates on the construction and uncovering of feminine sexual pleasure as it might be given shape in a subversive practice of writing, but the implicit background is Derrida's analysis of *différance* and the poststructuralist problematizing of logos, power and knowledge. Cixous takes up the notion of the feminine as symbolically other, plural and multivocal, positioned as such by the classical oppositions which classify and divide values. Her texts may be said to work at the knots which tie such an economy in place, loosening the rigidity of dualisms to free the expression of heterogeneity. Through the exploration of this more open and fluid form of difference, from the strategic standpoint of a woman 'lost' in her corporeal sexuality, her dreams of her marginalized, inessential nature, Cixous believes that the fixity of our present conceptual schema will be shaken. Her work initiates and celebrates the

experiential dimensions of feminine desire. She raids classical literature to uncover 'lost voices' through reinvesting in powerful figures—mothers, mythical heroines, goddesses and the ecstatic and excessive aspects of a sexual 'dark continent'. It is also an attempt to enrich a particular vocabulary coextensive with 'the feminine'; poetic and allusive, metaphorical and 'incandescent'. Rather than merely replicating the static, fragmented or silenced position she has diagnosed women as occupying, her texts attempt to transgress these positions by 'overloading' them, and lyrically exploding them. The notions of 'spending' and 'the gift' are significant in her piece 'Sorties':[83] showing up an economy of exchange to be one of exploitation by miming its carefully monitored limits to the point of parody is for Cixous a political and transgressive activity.

There are many problematic aspects of Cixous' work—she may seem to lapse into the versions of women's bodies she was critical of, or into a fascination with her own fabulous textual labyrinths at the expense of more explicit political engagement. She does extricate herself from any collective feminism which she believes to be a quest for recognition and legitimation in an inadequately interrogated patriarchal economy and so a 'reactionary ideology'. It is also unclear whether Cixous is celebrating and uncovering the quintessential 'feminine' in her work, or if she is demonstrating a strategy which all women are invited to explore for themselves. The use of 'we' for women in her texts is an ambivalent point in this regard. However, the celebratory tone of her texts is inspirational and creative: 'a laughter that breaks out, overflows, a humour no one would expect to find in a woman… she who laughs last. And her first laugh is at herself.'[84]

CONCLUSION

The philosophical paradox of scepticism bears, I think, many similarities to feminist work in philosophy. 'Scepticism may be understood as an expression of an extreme form of dissatisfaction with the logos in its philosophical form. Scepticism tries to evade philosophy; but is there any logos-free space where it could settle to enjoy a human life?'[85] If thinking is continually involved in movements of imprisonment, encompassing and repulsing, 'Which experiences, adventures of the mind, or events of history do not permit the gathering of logos to enclose them within its horizons?'[86] How are we to find a strategy of critique which is not merely repetition of the same, but manages to avoid the infinite regress of a scepticism forced to be sceptical of its own position? This is the problematic which faces those thinkers who seek to reproach philosophy for what it has repressed or left out, and to reproach it in the name of a legitimate cause, and yet this reproach contaminates the basis of an appeal to legitimation in reproaching philosophy. How to dodge philosophical containment while at the same time utilizing its resources to articulate otherness? Engaging in this 'impossible' enterprise is to offer an ethical reproach to philosophy, the conditions of this reproach being a determination to avoid quietism.

The questioning of identity belongs to an immense volume of work which aims to uncover the conflation of singularity, ontology and presence, and the connection to the power structures which not only create such formations but maintain them as the most successful means of sustaining the status quo. The totalitarian thinking which occludes

difference in the name of a more coherent theorization of unity is not confined to those political regimes more immediately identifiable as repressive, but also to the liberal framework which argues for equality at the expense of celebrating difference. If feminist theory has been concerned to question identity in the context of postmodernist thinking, it is in order to analyse the alignment of presence and power. But the recent 'return to the subject' in philosophical theory, which is heralded as the chance to reconsider questions of ethics and political responsibility now that subjectivity has been unsettled from its complacent fixity, is not really new to feminist theory, in that feminism is in general seeking an effective version of agency to be able to conduct a struggle, whether reformist or revolutionary.

NOTES

1 See M.E.Waite (ed.) [12.87].
2 In [12.85], 169, G.Spivak suggests that the professional woman philosopher may be comparable to Athena: 'Women armed with deconstruction must be aware of becoming Athenas, uncontaminated by the womb, sprung in armour from the father's forehead'.
3 A.Schopenhauer, 'On Women', in [12.84], 102–13.
4 I.Kant [12.69].
5 See some of the contributors to [12.87].
6 Many feminists have drawn attention to masculine traits in philosophy (see [12.73, 12–80] for examples) although this does not often extend so far as to see philosophy as all and irredeemably 'male'.
7 I have tried to include a representative sample of feminist philosophers in the Bibliography.
8 See E.Young-Bruehl [12.93], and C.Herman, 'Women in Space and Time', in E.Marks and I.de Courtivron (eds), *New French Feminisms, an Anthology* (Brighton: Harvester, 1980), pp. 168–74, for just two examples of feminist readings of Arendt and Weil.
9 See A.Jardine [12.68], R.Braidotti [12.50] or E.Grosz [12.65] for a mapping of the influence of such thinkers on contemporary feminist theory.
10 The works cited in note 9 also give examples of critiques of these thinkers. See also A.Nye [12.79].
11 J.Baudrillard [12.46], 8.
12 *Ibid.,* p. 9.
13 See J.Derrida [12.57], J.-F.Lyotard, 'One of the Things at Stake in Women's Struggles', in A.Benjamin (ed.), *The Lyotard Reader* (Oxford: Blackwell, 1989), pp. 111–21, or G.Deleuze [12.57] for examples of the fragmentation and dispersal of identity being linked to the feminine.
14 Texts dealing with Sartre's and de Beauvoir's relationship are extensive: see for example M.Le Doeuff's discussion in *Hipparchia's Choice* [12.43]. Many of the themes discussed above are given shape in de Beauvoir's novels, for example in *The Woman Destroyed,* or in her short stories, *When the Things of the Spirit Come First*. Portraits of women struggling with social contradictions and moral dilemmas and attempting, succeeding or failing to assert their freedom, complement her more theoretical work on this topic. Such themes are also given poignant expression in her autobiography, from 'dutiful daughter' to 'old age'.
15 S.de Beauvoir [12.27].

17 S.de Beauvoir *The Second Sex* [12.28].
18 *Ibid.,* p. 13.
19 M.Le Doeuff, *Hipparchia's Choice* [12.43], 58.
20 De Beauvoir, *The Second Sex* [12.28], 15.
21 *Ibid.,* p. 28.
22 *Ibid.,* p. 29.
23 *Ibid.,* p. 16.
24 *Ibid.,* pp. 35–69.
25 *Ibid.,* p. 62.
26 Ibid., p. 57.
27 See G.Lloyd [12.73], 102, for a discussion of this paradox in relation to de Beauvoir.
28 De Beauvoir, *The Second Sex* [12.28], 249.
29 *Ibid.,* p. 66. De Beauvoir also considers a Marxist analysis of sexual difference, which attributes inequalities to economic conditions and the historical development and transmission of such conditions. The division of labour which leads to the unequal distribution of property and wealth still does not explain why women should be seen as secondary, confined to the home and themselves valued as part of property. Sexual difference cuts across all class distinctions, yet in each class women are seen as subordinate. Although she agrees that at some indeterminate moment in history women became the other for men, and, once occupying a secondary role, continued to perpetuate such conditions through the centuries, she rejects the idea that the abolition of the family will resolve women's subordination, since without a fuller account of interpersonal relations (how dominant and subordinate roles between individuals come about), she argues, the inequalities may continue to exist.
30 See J.Pilardi, 'Female Eroticism in the Works of Simone de Beauvoir', in J. Allen and I.M.Young (eds) [12.44], 18–34. Another aspect of sexuality which de Beauvoir explores is the psycho-physical development of an individual in the context of the family. She agrees with Freud that women's positioning as subordinate is a consequence of her own emotional and sexual development, as a woman she identifies with or reacts against certain models of sexuality and incorporates such attitudes into her own self-understanding. But she also questions the universality of the Freudian scheme, being suspicious of the apparent inevitability with which men and women achieve their sexual identity in Freud's view, motivated by drives and prohibitions into particular socially determined roles, mainly because it represents an encroachment on her valorization of freedom.
31 See C.Duchen [12.61] for a clear historical perspective on the shifts in thinking.
32 See E.Grosz [12.66].
33 See J.Mitchell and J.Rose (eds) [12.76], or J.Gallop [12.63], for discussions of this influence. Feminist theory influenced by ego-psychology and object relations psychoanalysis, such as the work of Jessica Benjamin or Nancy Chodorow ([12.48], [12.54]) differs, in that it tends to analyse patterns of identification and difference or relations of dominance and submission between individuals, rather than the fragmented individual of Lacanian theory.
34 J.Rose, cited in G.C.Spivak, 'Feminism and Deconstruction, Again: Negotiating Unacknowledged Maculinism', in T.Brennan (ed.) [12.51], 206–24.
35 *Ibid*.
36 J.Mitchell and J.Rose (eds) [12.76], 166.
37 *Ibid.,* p. 147.
38 Although this is Freud's phrase, it is often used to describe feminist theory influenced by psychoanalysis.

39 See J.Lechte [12.72] for an account of Kristeva's work and influences upon her.
40 J.Kristeva, *Revolution in Poetic Language* [12.35], Only the first part is translated. The poets she discusses in the later section are Lautréamont and Mallarmé.
41 *Ibid.,* p. 22.
42 See Lechte [12.72], 32, where he writes: 'On 7 November 1955, Jacques Lacan—doctor of medicine, psychoanalyst, friend of surrealism—"officially" announced his famous "return to Freud" in a paper given at a neuro-psychiatric clinic in Vienna.' See J.Lacan, The Freudian Thing, or the Meaning of the Return to Freud in Psychoanalysis' in [12.71], 114–45.
43 Lacan writes: 'It is the name-of-the-father that we must recognize as the support of the symbolic function, which from the dawn of history has identified his person with the figure of the law' [12.71], 67.

49 *Ibid.,* p. 36.
50 *Ibid.,* p. 16.
51 *Ibid.,* p. 35.
52 Kristeva 'Stabat Mater' in *Tales of Love* [12.40], and in *The Kristeva Reader* [12.41]. Quotations from *The Kristeva Reader*.
53 *Ibid.,* p. 185.
54 M.Warner [12.88].
55 Kristeva 'Stabat Mater', in [12.40], 162.
56 R.Braidotti [12.50], 219. In contrast to the so-called 'feminists of difference' stand those thinkers who see all identity as social construction, and as a consequence see the notion of sexual difference as constructed. Such thinkers as Monique Plaza and Christine Delphy return to the ground of materialist/ humanist thinking because they see the adoption of sexual difference and 'the language of the female body' as too hasty or naive, in the face of the material and social oppression which women face. While it may be timely to remind philosophy of such concerns, overall the rejection of difference may lead once again to the marginalization or postponement of issues about sexual difference, or to very specific or localized areas of concern. Monique Wittig is perhaps an example of this approach. She rejects all binarisms of male/female or masculine/ feminine, and opts for a 'third' category, the lesbian, which, in her terms, involves advancing a strategic utopia and utilizing guerrilla-type tactics of subversion. Opting out or refusing any given terms may ultimately render this tactic less than effective.

CHAPTER 13
Deconstruction and Derrida

Simon Critchley and Timothy Mooney

DERRIDIAN DECONSTRUCTION[1]

In the last twenty-five years or so, particularly in the English-speaking world, no philosopher has attracted more notoriety, controversy and misunderstanding than Jacques Derrida. Caricatural summaries of deconstruction and 'deconstructionism' abound in introductory textbooks, newspaper articles, radio and television programmes. The word 'deconstruction' has found a home in everyday language, and positions pro and contra Derrida are taken up and held with a vehemence that is difficult for the uninitiated to grasp. 'Derrida' and 'deconstruction' have become integral terms in the debate on the meaning of western culture in the late twentieth century. However, in this chapter I would like to take a step back from the sound and fury of the cultural debate around Derrida and sketch, as clearly and simply as possible, what appears to take place in deconstruction, that is to say, what is the method of reading employed by Derrida and what, in brief, are the consequences of the latter for the philosophical tradition.

What is deconstruction? Or, as it is perhaps initially easier to give a negative response to this question, what is *not* deconstruction? Employing a short text of Derrida written in 1983 and published in 1985, 'Letter to a Japanese Friend', which was specifically written in order to aid the possible translation of the word *déconstruction* into Japanese, one can quickly sketch some important caveats. First, Derrida insists that deconstruction is not negative; it is not a process of demolition (which does not automatically entail that deconstruction is positive—[13.17], 390). Furthermore, deconstruction needs to be sharply distinguished from analysis, which presupposes a reduction of entities to their simple or essential elements, elements which themselves would stand in need of deconstruction. Crucially, deconstruction is not critique, either in the general or Kantian sense; Derrida writes, 'The instance of the *krinein* or of *krisis* (decision, choice, judgement, discernment) is itself, as is moreover the entire apparatus of transcendental critique, one of the essential "themes" or "objects" of deconstruction' ([13.17], 390). Similarly, deconstruction is not a method or way that can be followed in the activity of interpretation. This is also to say that deconstruction cannot be reduced to being a methodology (amongst competing methodologies) in the human or natural sciences, or becoming a technical procedure assimilable by academics and taught in educational institutions ([13.17], 390–1). In addition, deconstruction is not an *act* produced and commanded by a subject, nor is it an *operation* that sets to work on a text or an institution. Derrida concludes the 'Letter' characteristically by writing, 'What deconstruction is not? But everything! What is deconstruction? But nothing!' ([13.17], 392). All ontological statements of the form 'deconstruction is x' miss the point a priori,

for it is precisely the ontological presuppositions of the copula that provide one of the enduring 'themes' of deconstruction. Rather, carefully avoiding the verb 'to be', Derrida claims that deconstruction takes place ('a lieu'), and that it does so wherever there 'is' something ('où il y a quelque chose'). Such is the *enigma* (Derrida's word—[13.17], 391) of deconstruction: it cannot be defined and therefore resists translation; it is not an entity or a thing, it is not univocal or unitary. Derrida writes, paying careful attention to reflexivity of the statement, 'Ça se déconstruit' ('It deconstructs itself, the *Ça* being both a translation of *Es*—the id, the unconscious—and a homophone for *Sa*—'Savoir Absolu', Absolute Knowing—[13.17], 391). It deconstructs itself wherever something takes place.

However, such a formulation, although subtle and faithful, risks being unhelpful because of its generality. Having taken on board the negative caveats in the problem of defining deconstruction, I should now like to assemble a more 'constructivist' account of deconstruction by asking the question: *how* does deconstruction take place? Derrida addressed this question concisely and lucidly in *Of Grammatology* (1967) [13.4, 13.29], in a chapter entitled, 'The Exorbitant. Question of Method'. The first essential point to make, however, trivial it may seem, is that deconstruction is always the deconstruction of a *text*. Derrida's thinking is always thinking *about* a text, from which flows the obvious corollary that deconstruction is always engaged in a *reading* of a text. The way of deconstruction is always opened through reading, what Derrida calls 'a first task, the most elementary of tasks' ([13.21], 35; [13.43], 41). Any thinking that is primarily concerned with reading will clearly be dependent upon the text that is being read. Thus, Derrida's readings are parasitic because they are close readings of texts that draw their sustenance from within the flesh of the host. What takes place in deconstruction is reading, and, I shall argue, what distinguishes deconstruction as a textual practice is *double reading*. That is to say, a reading that interlaces at least two motifs or layers of reading, most often by first repeating what Derrida calls 'the dominant interpretation' ([13.22], 265; [13.44], 143) of a text in the guise of a commentary, and second, within and through this repetition, by leaving the order of commentary and opening a text up to the blind spots or ellipses within the dominant interpretation.

Now, when Derrida reads Rousseau, he organizes his reading around the word *supplément.* It is claimed that this word is the 'blind spot' *(tâche aveugle* [13.4], 234; [13.29], 163) in Rousseau's text, a word which he employs but whose logic is veiled to him.[2] Derrida's reading of Rousseau traces the logic of this supplement, a logic which allows Rousseau's text to slip from the grip of its intentions and achieve a textual position that is other than the logocentric conceptuality that Rousseau intended to affirm. Thus, Derrida's reading of Rousseau occupies the space between the writer's intentions and the text, or between what a writer commands and fails to command in a language. It is into this space between intentions and text that Derrida inserts what he calls the 'signifying structure' ([13.4], 227; [13.29], 158) of the reading that constitutes part two of *Of Grammatology*.

How does one perform a deconstructive reading? In 'The Exorbitant. Question of Method', Derrida pauses in his reading of Rousseau in order to justify his own methodological principles. The signifying structure of a deconstructive reading cannot, he claims, simply be produced through the 'respectful doubling of commentary' ([13.4], 227; [13.29], 158). Although Derrida is acutely aware of the exigencies of the traditional

instruments of commentary as an 'indispensable guardrail' in critical production, he claims that commentary 'has always only *protected,* it has never *opened,* a reading' *(ibid.)*.

Here I would like to pause for a moment to consider what Derrida could possibly mean by the word 'commentary' in this context: is he claiming, oblivious to the achievements of Heideggerian and especially Gadamerian hermeneutics, that there can be a pure commentary or literal repetition of a text that is not already an interpretation? Derrida corrects and clarifies the above remarks from *Of Grammatology* in one of his responses to Gerald Graff in the 'Afterword' to *Limited Inc*. Derrida writes that 'the moment of what I called, perhaps clumsily, "doubling commentary" does not suppose the self-identity of "meaning", but a relative stability of the dominant interpretation (including the auto-interpretation) of the text being commented upon'. He continues, 'perhaps I should not have called it commentary' ([13.22], 265; [13.44], 143). Thus, for Derrida, the moment of commentary refers to the reproducibility and stability of the dominant interpretation of a text, for example the traditional logocentric reading (or misreading) of Rousseau. Commentary is always already interpretation and Derrida does not believe in the possibility of a pure and simple repetition of a text. However, and this is a crucial caveat, there is an unavoidable need for a competence in reading and writing such that the dominant interpretation of a text can be reconstructed as a necessary and indispensable layer or moment of reading. 'Otherwise', Derrida writes, echoing a sentence from *Of Grammatology* effectively ignored by many of its opponents and proponents alike, 'one could indeed say just anything at all and I have never accepted saying, or being encouraged to say, just anything at all' ([13.22], 267; [13.44], 144–5; cf. [13.4], 227; [13.29], 158).

Derrida goes on to argue that the moment of 'commentary' or of the dominant interpretation reflects a minimal *consensus* concerning the intelligibility of texts, establishing what a given text means for a community of readers. Although such a search for consensus is 'actively interpretive', Derrida adds, 'I believe that no research is possible in a community (for example, academic) without the prior search for this minimal consensus' ([13.22], 269; [13.44], 146). Thus, although 'commentary' alone does not open a genuine reading, the latter is not possible without the moment of commentary, without a scholarly competence in reading, understanding and writing, without a knowledge of texts in their original languages (for example, Rousseau's or Derrida's French), without knowing the corpus of an author as a whole, without knowing the multiple contexts—political, literary, philosophical, historical and so forth—which determine a given text or are determined by that text. This is what one might call the deconstructive duty of scholarship. I would go further and claim that there is a hermeneutic principle of fidelity—one might even say 'an "ethico-political duty"' ('un "devoir éthico-politique"') ([13.22], 249; [13.44], 135)—and a minimal working notion of truth as *adaequatio* underlying deconstructive reading, as its primary layer of reading. If deconstructive reading is to possess any demonstrative necessity, it is initially in virtue of how faithfully it reconstructs the dominant interpretation of a text in a layer of 'commentary'.

To choose an extreme example, in *Limited Inc*. every word of Searle's 'Reiterating the Differences: A Reply to Derrida' is repeated or re-reiterated. Derrida clearly views this as

a way of responding responsibly to the brutality of Searle's essay, which decides to 'insult' ([13.22], 257; [13.44], 139) Derrida's work—for example Searle writes of 'Derrida's distressing penchant for saying things that are obviously false'[3] rather than engaging in the necessary critical demonstration. Thus, bearing the above qualifications in mind, one might say a reading is *true in* the first instance to the extent that it faithfully repeats or corresponds to what is said in the text that is being commented upon. This is perhaps the reason why Derrida quotes at such length and with such regularity in his writings, and it is also the basis for his accusation of falsity against Habermas's critique of his work in 'Excursus on Leveling the Genre Distinction between Philosophy and Literature', where Derrida is not cited a single time ([13.22], 244; [13.44], 156).[4]

Returning to *Of Grammatology,* it is clear that although the respectful repetition of the text which 'commentary' produces fails to open a reading, this in no way entails that one should then transgress the text by reductively relating it to some referent or signified outside of textuality (i.e. historical material or the psychobiography of the author). To determine textual signifiers by referring them to a governing signified—for example, to read *A la recherche* in terms of Proust's asthma—would be to give what Derrida calls a transcendent reading. The axial proposition of *Of Grammatology* is 'il n'y a pas de horstexte' ('there is no outside text' [13.4], 227; [13.29], 158), or again, 'il n'y a rien hors du texte' ('there is nothing outside of the text' [13.4], 233; [13.29], 163). One should be attentive to the nuanced difference between these two sentences: the first claims that there is no 'outside-text', no text outside; whilst the second claims that there is *nothing* outside of the text, the text outside is nothing), implying by this that any reading that refers the text to some signified outside of textuality is illusory. Within the logocentric epoch, the textual signifier (and writing, inscription, the mark and the trace in general) has always been determined as secondary, as a fallen exteriority preceded by a signified. A deconstructive reading must, therefore, remain within the limits of textuality, hatching its eggs within the flesh of the host.

Thus, the 'methodological' problem for deconstruction becomes one of discovering how a reading can remain internal to the text and within the limits of textuality without merely repeating the text in the manner of a 'commentary'. To borrow the adverbial phrase with which Derrida describes his reading of Husserl, deconstructive reading must move *à travers* the text, *traversing* the space between a repetitive commentary and a metatextual interpretation, *'Traversing [à travers]* Husserl's text, that is to say, in a reading which cannot simply be that of commentary nor that of interpretation' ([13.2], 98; [13.27], 88). By opening up this textual space that is other to 'commentary' or interpretation, a certain distance is created between deconstructive reading and logocentric conceptuality. The signifying structure of a deconstructive reading traverses a space that is other to logocentrism and which attempts eccentrically to exceed the orbit of its conceptual totality. In an important and explicit reference to the 'goal' or 'aim' of deconstruc-tion, Derrida writes, 'We wanted to attain the point of a certain exteriority with respect to the totality of the logocentric epoch. From this point of exteriority a certain deconstruction of this totality… could be broached *[entamée]*' ([13–4], 231; [13.29], 161–2). It is from such a point of exteriority that deconstruction could cut into or penetrate the totality, thereby displacing it. The goal of deconstruction, therefore, is to locate a point of otherness within philosophical or logocentric conceptuality and then to

deconstruct this conceptuality from that position of alterity.

It is at this point that the concept of double reading can be properly understood. If the first moment of reading is the rigorous and scholarly reconstruction of the dominant interpretation of a text, its *vouloir-dire,* its intended meaning, in the guise of a commentary, then the second moment of reading, in virtue of which deconstruction obeys a double necessity, is *the destabilization of the stability of the dominant interpretation* ([13.22], 271; [13.44], 147). It is the movement of traversing the text which enables the reading to obtain a position of alterity or exteriority from where the text can be deconstructed. The second moment brings the text into contradiction with itself, opening its intended meaning, its *vouloir-dire,* onto an alterity which goes against what the text wants to say or mean ('ce que le texte veut dire'). Derrida often articulates this double reading around a semantic ambivalence in the usage of a particular word, like *supplément* in Rousseau, *pharmakon* in Plato or *Geist* in Heidegger. It is of absolutely crucial importance that this second moment, that of alterity, should be shown to arise necessarily out of the first moment of repetitive commentary. Derrida ventriloquizes this double structure through the mouth of Heidegger in *De l'esprit:* 'That is why, without opposing myself to that of which I am trying to think the most matinal possibility, without even using words other than those of the tradition, I follow the path of a repetition which crosses the path of the wholly other. The wholly other announces itself within the most rigorous repetition ([13.18], 184).' Thus, by following the path of a repetition, the *Wiederholung* of a text or a tradition, one inevitably crosses the path of something wholly other, something that cannot be reduced to what the text or tradition wants to say. It is at this point that the similarities between Derridian deconstruction and Heideggerian *Destruktion* become apparent. Indeed, Derrida initially employed the term *déconstruction* as an attempt to render into French the Heideggerian notions of *Destruktion* (de-struction, or non-negative de-structuring) and *Abbau* (demolition or, better, dismantling—[13.17], 388). For the Heidegger of *Being and Time,* the working out or elaboration *(Ausarbeitung)* of the question of the meaning of Being does not become truly concrete until the ontological tradition—that is, the tradition that has forgotten the question of Being, and more precisely the *temporal* dimension of this question—has been completely repeated *(wiederholen)* and deconstructed.[5] In the 1962 lecture 'Time and Being', *Abbau* is presented (and presented, moreover, as a synonym for *Destruktion)* as the progressive removal of the concealing layers that have covered over the first Greek rending of Being as presence *(Anwesenheit)*. The repetition of the metaphysical tradition is a dismantling that reveals its unsaid *as* unsaid.[6] Returning to Derrida, it is the belonging together or interlacing of these two moments or paths of reading—repetition and alterity—that best describes the double gesture of deconstructive reading: the figure of the chiasmus.

What takes place in deconstruction is double reading, that is, a form of reading that obeys the double injunction for both repetition and the alterity that arises within that repetition. Deconstruction opens a reading by locating a moment of alterity within a text. In Derrida's reading of Rousseau, the concept of the supplement is the lever that is employed to show how Rousseau's discourse is inscribed within the general text, a domain of textuality irreducible to logocentric conceptuality. In this way one can see how a moment of blindness in a logocentric text grants insight into an alterity that exceeds logocentrism. As Derrida remarks in an interview with Richard Kearney, 'deconstruction

is not an enclosure in nothingness, but an openness towards the other'.[7] What takes place in deconstruction is a highly determinate form of double reading which pursues alterities within texts, primarily philosophical texts. In this way, deconstruction opens a discourse on the other to philosophy, an otherness that has been dissimulated or appropriated by the logocentric tradition. Philosophy, particularly in its Hegelian moment, has always insisted on thinking its other (art, religion, nature, etc.) as its *proper* other and thereby appropriating it and losing sight of its otherness. The philosophical text has always believed itself to be in control of the margin of its own volume ([13.5], 1; [13.30], x). As Emmanuel Levinas points out in 'Transcendence and Height', philosophy might be defined as the activity of assimilating all otherness into the Same.[8] Such a definition would seem to be accurate in so far as the philosophical tradition has always attempted to understand and *think* the plurality and alterity of a manifold of entities through a reduction of plurality to unity and alterity to sameness. The same gesture is repeated throughout the philosophical tradition, whether it be in Plato, where the plurality of the instances of an entity *(phainomena)* are understood in relation to a unifying form *(eidos)*. Or whether it be Aristotle, where *philosophia protē* (that is to say, metaphysics) is the attempt to understand the Being of a plurality of entities in relation to a unifying substance *(ousia),* and, ultimately, a divine *ousia:* the god *(to theion)*. Or, indeed, whether it be in terms of Kantian epistemology, where the manifold or plurality of intuitions are brought into unity and sameness by being placed under concepts which are regulated by the categories of the understanding (and other examples could be cited).

The very activity of thinking, which lies at the basis of epistemological, ontological and veridical comprehension, is the reduction of plurality to unity and alterity to sameness. The activity of philosophy, the very task of thinking, is the reduction and domestication of otherness. In seeking to think the other, its otherness is reduced or appropriated to our understanding. To think philosophically is to comprehend—*comprendre, comprehendere, begreifen,* to comprehend, to include, to seize, to grasp—and master the other, thereby reducing its alterity. As Rodolphe Gasché points out, 'Western philosophy is in essence the attempt to domesticate Otherness, since what we understand by thought is nothing but such a project.'[9] As the attempt to attain a point of exteriority to logocentrism, deconstruction may therefore be 'understood' as the desire to keep open a dimension of alterity which can neither be reduced, comprehended, nor, strictly speaking, even *thought* by philosophy. To say that the goal of Derridian deconstruction is not simply the *unthought* of the tradition, but rather 'that-which-cannot-be-thought' is to engage neither in sophistical rhetoric nor negative theology. It is rather to point towards that which philosophy is unable to say.

Derridian deconstruction attempts to situate, 'a non-site, or a non-philosophical site, from which to question philosophy'.[10] It seeks a place of exteriority, alterity or marginality irreducible to philosophy. Deconstruction is the writing of a margin that cannot be represented by philosophy. In question is an other to philosophy that has never been and cannot become philosophy's other, but an other within which philosophy becomes inscribed.

However (and this is crucial), the paradox that haunts Derrida's and all deconstructive discourse is that the only language that is available to deconstruction is that of philosophy or logocentrism. Thus to take up a position exterior to logocentrism, if such a thing were

possible, would be to risk starving oneself of the very linguistic resources with which one must deconstruct logocentrism. The deconstructive reader is like a tightrope walker who risks 'ceaselessly falling back inside that which he deconstructs' ([13.4], 25; [13.29], 14). Deconstruction is a double reading that operates within a double bind of both belonging to a tradition, a language and a philosophical discourse, and at the same time being unable to belong to the latter. This ambiguous situation of belonging and not-belonging describes the problem of *closure*.

Broadly stated,[11] the problem of closure describes the duplicitous historical moment—*now*—when language, conceptuality, institutions and philosophy itself show themselves to belong to a logocentric tradition which is theoretically exhausted whilst at the same time searching for the breakthrough from that tradition. The problem of closure describes the liminal situation of modernity out of which the deconstructive problematic arises and which Derrida inherits from Heidegger. Closure is the double refusal both of remaining within the limits of the tradition and of the possibility of transgressing that limit within philosophical language. At the moment of historical and philosophical closure, deconstructive reading takes place as the disturbance, disruption or interruption of the limit that divides the inside from the outside of the tradition. A deconstructive reading shows how a text is dependent upon the presuppositions of a metaphysics of presence of logocentrism, which that text might attempt either to champion or dissimulate, whilst at the same time showing how that text radically questions the metaphysics it presupposes, entering into contradiction with itself, and pointing the way towards a thinking that would be other to logocentrism. Closure is the hinge that articulates this double and strictly undecidable movement between logocentrism and its other. Deconstruction(s) take(s) place as the articulation of this hinge.

Simon Critchley

PHILOSOPHICAL ROOTS AND BIBLIOGRAPHICAL HISTORY

Throughout the history of thought new philosophies have unfolded as reactions to or developments of previous ones, and in this way have shown their indebtedness to their forebears. There is no field outside the philosophical tradition from which a completely new thinking could spring into being. Starting from the recognition of this fact, the first part of this section seeks to show how some of Jacques Derrida's central ideas develop out of his encounters with the work of Edmund Husserl. Charting the ground of an individual's thought with any fidelity is always a difficult exercise, the more so in Derrida's case. He has cited and displayed evidence of numerous influences, including Heidegger, Hegel, Levinas, Nietzsche, Freud and Saussure, and his own arguments have cast doubt on the possibility of uncovering simple origins or foundations. All this being said, however, the crucial importance of Husserl's phenomenology can still be clearly demonstrated. Outlining Derrida's readings of Husserl also shows that he has engaged in philosophical argumentation rather than in some esoteric anarchism that is supposedly closed off from all criticism.

The second part of this section attempts to give a concise overview of Derrida's philosophical career within the broad framework of a bibliographical history. Reference

will be made to his most important works and to the way in which they follow on from certain questions articulated in the early texts. This is also a difficult task. From the close of the 1950s Derrida has published twenty-six books and innumerable articles, many of them extending into the associated regions of literary criticism, aesthetics and politics. These factors alone militate against the adequacy of short summaries and chronological surveys, quite apart from specifically theoretical objections. Perhaps the best combination of clarity and continuity lies in confining one's attention to those philosophical concerns that stand out most strongly in the Derridian constellation. It is this approach that has been adopted here.

It was as a teenager in Algeria that Derrida first became interested in philosophy. He read Sartre copiously, and was spurred into enrolling for pre-university classes after hearing a radio broadcast by Albert Camus. In 1949 Derrida went to Paris, where he commenced his studies under Jean Hyppolite at the Ecole Normale Supérieure. As far as can be ascertained, Derrida's interest in Sartre waned from the moment he became acquainted with the work of Husserl. The latter's phenomenology, as opposed to the version propounded by Sartre, appeared to Derrida as an inescapable method of analysis. As recently as 1980, Derrida has remarked that he still sees it, although in a different way, as a discipline of incomparable rigour.[12]

Derrida's first article was entitled '"Genesis and Structure" and Phenomenology'. Published in 1959, this was a development of part of his master's thesis. The problem of genesis or origin and structure had emerged as a result of Husserl's insistence that the meanings of those objects and states of affairs taken as irreducible to what we call the conscious self are never immediately given from outside. There are no transparently intelligible meanings in phenomena which would fall like manna from a heavenly place *(topos ouranios)* and strike the mind ready-made. In all these cases meaning demands not just a subject but a complex subjective contribution. All of the objects or states of affairs that we can entertain must be taken as more than an amorphous fuzz of unceasing mutation. Without at least a relative constancy in phenomena, recognition and discrimination would be impossible. Yet these constancies themselves presuppose a wider horizonal structure within which we ourselves place every appearance. Recognition and discrimination point to a surround of expectations which phenomenology seeks to make explicit. We expect physical objects, for instance, to have currently invisible aspects which can be brought into view, or made present, as we vary our perspective. We also expect physical things to behave in certain ways. On this view everything experienced is implicitly contextualized, whether it pertains to the physical, scientific or cultural worlds.

Unlike the Kantian categories of experience and understanding, Husserl's horizons are not fixed but constantly evolving. Through successive acts of perception we adjust each horizon so that it more comprehensively contextualizes objects or states of affairs. Meaning emerges from a weave made up of changing horizons and their contents. This creative emergence of meaning Husserl calls *constitution*. To explain any constituted phenomenon adequately, we have to give a structural description of this phenomenon and of our present mode of consciousness of it. But we also have to give a genetic or originary description of the evolving horizon which the phenomenon and our mode of consciousness of it presuppose.

According to Derrida, certain insoluble problems ensue from this approach, stemming from the fact that the isolation and description of the objective structures of phenomena and of the horizons through which they are revealed is, on Husserl's premisses, an infinite task. Because we must describe ever anew our continually evolving horizons, we will at the same time be altering our correlative characterizations of the objective structures of phenomena. What now appear as foundational structures could well be shown to be derivative in the future. Being caught up in history, we can never claim to encounter closed or finished structures, that is, structures that would be immune from modification and deposition. Yet another problem is that of discerning where our horizons end and where the objective structures of phenomena begin. There are no sure criteria for distinguishing between the 'productive' and 'revelatory' aspects of certain constituted meanings.

Derrida does not claim any great novelty in this analysis, and he stresses that these difficulties could never have been brought to light were they not built upon Husserl's powers of insight. It is the critical drive in Husserl that foregrounds these problems as he attempts to get back to the things themselves, to describe faithfully the phenomena presented to consciousness.

Derrida does not accept the Husserlian argument that the living present *(lebendige Gegenwart)* of human consciousness is the ultimate locus and ground of meaning. He takes over the structuralist position that meaning depends on sign-systems that transcend the intentional control of individual subjects. There is no self and no other than can be understood apart from signs. The move towards this position is marked in Derrida's first book, *Edmund Husserl's Origin of Geometry, an Introduction* (1962) [13.1; 13.26]. All the problems treated in this early text, according to Derrida, have continued to organize the work he has subsequently embarked upon.[13]

In *The Origin of Geometry* (1936), written shortly before his death and published only posthumously, Husserl was concerned with the communicability of ideal objects, such as geometrical formations, that are initially reached or constituted in an individual human consciousness. Being universal and non-perspectival, geometrical idealities are free from the contingencies of spatio-temporal existence, and in terms of perfection, argues Husserl, they can serve as the model for any object whatsoever. But precisely because of their ideality, they must in principle be accessible to every rational being, capable of being objects for all conscious subjects. One of the core concerns in *The Origin of Geometry* is to explain how a geometrical formation which is initially confined to the solitary psychological life of the first or proto-geometer can become intersubjective, that is, an object for the whole human community.

Husserl's immediate answer is that it is speech which brings ideality into the public realm, allowing the proto-geometer to share his or her discovery with others in the same community. But it is only writing that allows the discovery to be transmitted from generation to generation, thus giving it a history. Through writing or inscription, the geometrical formation is passed down to others, who add corollaries and formulate further theorems and axioms. Through successive generations, new layers are added on top of the original formation. This is the path of scientific progress, and indeed of cultural development in general, and it resembles an elevated rock stratum composed of various sedimented layers. Through encoding the original discovery, the protogeometer sends it

forward in a productive passage through time. The price of productive written transmission, however, is the loss of the conscious intentional states of the proto-geometer's mind that led to his or her discovery. Writing is an autonomous field that can virtualize a discovery, separating a bare formation from the conscious acts of constitution that are communicable through the tone and facial expressions of everyday speech. This loss is itself a condition of progress, for later geometers have to take the bare formation as a readymade given so as to have the time to improve on it. Quite apart from the comparative shortness of wakeful life, our bodily needs leave us little enough time for research. All the productive arts and sciences, argues Husserl, have to progress in this way. But it is just this element of loss in writing that has led to the contemporary crisis in western civilization. We have lost our roots, our sense of where we came from, of how and why our scientific and cultural traditions began.

Husserl regards this state of crisis as endemic—it can never be overcome. The intentional states of the founders of our traditions are lost for ever, and there is no return-enquiry *(Rückfrage)* that could recover them. But if we cannot reactivate the primordial *archē* of a science in our present age, argues Husserl, we can at least envisage its *telos,* which is that of a complete system of knowledge, of absolutely transparent and univocal understanding. This is not something that can ever be fully actualized; rather it functions as a infinite ideal. The building up of a science on top of an original formation can be understood as a gradual process of approximation towards this ideal. The actual formation can be understood as an essential element within this process that contributes to its determination. In this regard it is described by Husserl as an 'Idea in the Kantian sense'. Only efficacious through writing, the ideal of objective and thorough knowledge and the correlative Idea in the Kantian sense may not constitute a knowledge of origins, but they do show that our scientific and cultural objects are not meaningless when recontextualized.

In his reading of this text, Derrida seeks to show that certain radical conclusions follow from Husserl's premisses. These were already touched upon by the latter, but never developed, perhaps because he well understood the problems they would pose for a text that valorized the notion of a unique and transparent origin of geometry and of other traditions in the living present of human consciousness. Derrida is careful to emphasize Husserl's acute awareness of the significance of language, and of writing in particular. Here we see the first direct articulation of the idea that language is more than a material body that receives an already constituted truth. Contributing to the clarification and systematization of a discovery, it is not a passive receptacle of something given ready-made. Constituting ideal objects as definite and repeatable formations, it is a necessary condition of truth, in principle as well as in fact:

> Husserl insists that truth is not fully objective, i.e, ideal, intelligible for everyone and indefinitely perdurable, as long as it cannot be said *and* written. Since this perdurability is truth's very sense, the conditions for its survival are included in its very life… freedom is only possible precisely from the *moment* truth *can* in general be said and written, i.e., *on condition* that this *can* be done. Paradoxically, the possibility of being written *[possibilité graphique]* permits the ultimate freeing of ideality…the *ability* of sense to be linguistically

embodied is the only means by which sense becomes nonspatiotemporal.[14]

This material condition of truth can also jettison what Husserl sees as the original meaning of a truth, its intentional origin. In philosophy and literature, as well as in the natural sciences, Husserl well appreciates the possibilities of loss and misunderstanding brought into play by writing. But what he fails to account for, Derrida goes on to argue, is the possibility of the total loss of a message in the autonomous field of writing. This eventuality is to be distinguished from an empirical catastrophe, such as a worldwide burning of books and defacing of monuments. In this case writing would be materially destroyed and the message consumed. What Derrida is adverting to is the possibility of the complete disappearance of a message in a writing that remains fully intact in the world. The writing that gives life after death to a message can just as well bury that message. As Derrida points out, we can see abundant evidence of this in those prehistoric artefacts and monuments that silently defy all comprehension and translation. That which is the condition of transmission through the ages is not a guarantor of the success of any such transmission.

Derrida rejects Husserl's suggestion that the intentional origin of geometry was unique to one particular person at one time. He maintains that the unpacking of the Idea in the Kantian sense undercuts any such suggestion. This, we may recall, is the notion of an ideal object as an essential element in a process of approximation towards a complete system of objective, univocal knowledge. Derrida's argument is that a person would have no appreciation of the ideality of geometry without possessing this notion, even if they chanced upon a bare geometrical formation in the empirical world. The proto-geometer could never understand the significance of such formations without some awareness of science, of its ultimate end.[15] This awareness would include some of the conditions that a formation would have to fulfill in order to have an essential status in any science. For this reason, the Idea in the Kantian sense is not just the end of geometry—it is its very origin. Anyone who attains to this idea begins in just as original and authentic a fashion as the chronologically first geometer, since it is not specific to any one culture at any one time. Apart from a brute empirical history of ownership and copyrights, Derrida wonders whether we can ever speak of a once-off or unrepeatable origin of geometry. Since the intentional origin of geometry need not be unique to any one factual individual, geometry could in principle have an infinite number of births and birth certificates, each one upstaging its forebears. On this view, it can be difficult to divide intentional acts into ones that are original on the one hand and derivative or parasitic on the other.

Perhaps the most important caveat that Derrida has in connection with *The Origin of Geometry* pertains to Husserl's suggestion that what is lost in writing was a transparent plenitude in its own time. This is the idea that the proto-geometer was adequately aware in the living present of consciousness of what he or she was about in constituting an ideal formation. The fact that the meaning of an ideal object as an Idea in the Kantian sense is universally accessible, notes Derrida, does not entail that this meaning is adequately given in the present. In fact and in principle, the project within which we understand the ideality and objectivity of a formation cannot be realized in the living present of a human subject. The present meaning is given by virtue of an ideal which is deferred *ad infinitum*. The sign that gives the object its meaning is the sign of something for ever absent, because the

realization of a complete science within which the significance of an ideal object would be transparently intelligible always recedes as we approach it. We can have the empty idea, but not that of which it is the idea. To comprehend the inability of consciousness to reach such an absolute is to comprehend the structural necessity of deferral, delay, or difference. As a structure of infinite anticipation devoid of final fulfilment, the absolute is a limit, a condition of possibility of meaning that cannot be imagined in itself alone. To make it real one would have to be an omnipotent God untrammelled by perspective and distance, eternally comprehending everything within its absolute gaze. The origin of geometry and of objectivities in general lies in a promised land which even the so-called proto-geometer never saw in the living present of consciousness. Even in its own time the past-present was never an undivided plentitude. The meaning of objectivity presupposed something that could never be brought into view.

Derrida's second book, translated as *Speech and Phenomena* [13.27], was published in 1967. Derrida has described this essay as the one which he likes most, because it raises in a 'juridicially decisive' way the 'privilege of the voice' as it occurs in western metaphysics in general and in Husserl in particular. He also says that this work can be read as the other side, the recto or verso, of the earlier *Introduction* ([13.27], 5). In the later work, Derrida focuses his attention on the Husserlian claim that the living present is based on an undivided immediacy of self-consciousness. In the *Introduction,* Derrida had already argued against the idea that we can ground the meaning of objectivity in an undivided present of consciousness. Now he will argue that this latter notion is a metaphysical illusion in itself. Reflective awareness or subjectivity is also dependent on the representation by the sign of something that cannot be made fully present.

In his account of conscious mental life in the *Logical Investigations* (1900–1), Husserl makes a distinction between a signified meaning that can be fully present to consciousness and one that can be only indirectly present. A meaning of the first type can be described as an expression *(Ausdruck)*. A meaning of the second type is anything conveyed through indication *(Anzeichen)*. In general terms, the world of indication is composed of those signs referring to things outside direct awareness. The function of an indicative sign is that of standing in for something that is completely or partially absent. Although it has its referent or signified, this type of sign is devoid of intrinsic meaning. To be more than an empty bearer or carrier it must be given meaning by a specific intention, though it may not transmit this in its fullness. When I read a book in which the author indicates something to me, for instance, I can grasp that something without intuiting his or her background intention as well as I could intuit an intention of my own.

In contrast to derivative indications, expressions are inherently meaningful and fully present to the self. They mean something and they express a meaning. Because an expression effectively includes content and object, it is a sign that almost immediately gives way to the actual thing that it signifies. Every expression can subsequently acquire an indicative function, for example when I communicate it' to another person via speech. In this case expression is given a phonic material body. It is this vehicle that allows it to enter into the arena of intersubjectivity. I can also communicate through writing, through a graphic material body. This puts expression into the historical field that threatens the perversion and loss of meaning. Writing lacks the immediacy of speech. When I make an utterance I can hear myself speak. I concretely experience and understand an indication

that has been permeated by an expression. What I say is present to me, under my intentional control. This immediacy can be lost in writing. When I write something, it can go out beyond my living present. The original immediacy is cast adrift with the indication, and fades into the dead letter on the page. Speech is the only material medium that safeguards the life of expressed intuitions, for it is a reflection of the uncontaminated immediacy of conscious life. This is why thinking is often described as a form of self-addressed inner speech. In the actual zone of conscious life, however, Husserl does not hold that the solitary mind engages in a silent dialogue with itself. In the interior field of pre-expressive intuition, we can only imagine mercurial messages flitting through the galleries of the transcendental ego. We have no need to communicate anything at this level because our meanings are immediately experienced and understood. Not even the blink of an eye can be held to separate an intention and my intuition of it. In the pure self-relation of reflective consciousness, the realm of signs is really quite useless *(ganz zwecklos)*.

Derrida rejects Husserl's initial prioritization of speech over writing, which he terms *phonocentrism*. This privilege of the voice is regarded by Derrida as a metaphysical assumption foreign to the rigour of a thoroughgoing phenomenological philosophy. Derrida points to the fact that Husserl characterizes most conscious intentions as imperfect or unfulfilled. In perception I intend the entire bureau that I am leaning on. Yet it is only partially present to me as a hard and black horizontal surface that I see with my eyes and touch with my elbows. In imagination I intend the cellars of Ludwig of Bavaria's fairytale castle. These are only present to me in so far as they can be envisaged without acquaintance or description. It is linguistic signs that stand in for these absences. We use these to denote objects and states of affairs that are either indirectly given or not given at all. On this description, signs can operate perfectly well in the complete absence of their object, and indeed this is one of their essential functions. But what about cases where the object, so to speak, is the human subject itself? We have to ask whether propositions with reflexive pronouns are properly meaningful in the absence of the subject that communicates them.

Husserl draws back from affirming this. He admits that we can understand the ordinary everyday meaning of a mathematical proposition, for example, quite apart from the circumstances of our use of it. We can read it without thinking of a particular person. But in a statement that uses the word 'I', such as 'I am alive', Husserl states that we can glean its proper meaning only from the individual intentions that permeate it at the time of its utterance or inscription. If we were to read this statement without knowing who wrote it, says Husserl, it might not be meaningless, but it would be alienated from its normal meaning. According to Derrida, however, such a proposition can and does function normally in the absence of a speaker or writer. 'I am alive' retains its normal meaning even when the original subject is dead or fictitious. The meaning borne in the reflexive sign or proposition does not have to be fulfilled by a personal intuition. Language has a life of its own in writing, and there is no good reason to think why the situation is any different in speech. Here also we have to allow for the transmigration of signs that have their own meaning. If the expressed personal intuition that my voice breathes into the sign were to give it its normal meaning, and if this were to stay with the sign, then everyone would have to use my own private language. According to Derrida:

> The absence of intuition—and therefore of the subject of the intuition—is not only *tolerated* by speech; it is *required* by the general structure of signification, when considered *in itself*. It is radically requisite: the total absence of the subject and object of a statement—the death of the writer and/or the disappearance of the objects he was able to describe—does not prevent a text from 'meaning' something. On the contrary, this possibility gives birth to meaning as such, gives it out to be heard and read.
>
> ([13.2], 104; [13.27], 93)

In the world that we actually find, the meaning of each and every sign is independent of whatever momentary intentional fulfilment the speaking or writing subject may give it. Precisely because he recognizes that language has its own life, Husserl tries to limit normal or proper meaning to the here and now of the speaking subject. Yet this subject, implicated in a living medium not under its control, has to stand like a watchguard over its utterances. We often enunciate a statement and immediately qualify it, aware that our intention does not encounter a neutral container. We hang around so as to catch certain 'normal' implications of the sign that we were not sufficiently aware of at the time of speaking or writing. And it could even be argued that writing is better than speaking inasmuch as it focuses the mind and enables greater clarity of expression, though again this is not safeguarded from perversion or loss in either medium.

Derrida is not content with exposing phonocentrism as an unjustified prejudice. He wants to show that the conception of an immediate, self-identical consciousness reflected in expression and subsequently cast into an impure world of indication itself falls down. Husserl argues that signs are redundant in the self-relation because we are present to ourselves in an undivided now, though he is very careful to qualify this last idea. This can be seen in a series of lectures which he composed between 1893 and 1917 and later published as *On the Phenomenology of the Consciousness of Internal Time* in 1928. Husserl here rejects out of hand any recourse to the notion of detached atomic instants of consciousness. Our conscious processes are always ongoing and interconnected, making up a flowing stream. Within this stream every present moment or immediate now of self-consciousness carries an inheritance from the past (retention) and an anticipation of the future (protention).

The past that is held in retention is different from a past that has to be reproduced. Reproduction is the recreation of an event that is completely over, one that lies in the more distant past. It is the reactivation of a dead event and it always involves some vagueness and distortion. Retention is the holding of an immediately lapsed past in the present moment of consciousness. It would be analogous to the hum of a dinner-gong that echoes on in my ears. The present-past of retention avoids the inevitable imperfection of reproduction, because there is no significant temporal lapse between the present moment and the immediately past one that makes up the content of the retention. I have to be conscious of the retentional content in the present moment to be conscious of the latter's immediacy. This can only be identified when I have an immediate past against which it can be contrasted.

As stated above, the present moment also involves a protention. This is an anticipation

of the next moment of awareness, the one that will immediately follow the now. Implicit in self-consciousness is the expectation that the now will pass into a new moment within which I shall be just as present to myself as I am in this one. I could of course switch attention, be knocked unconscious or drop dead, but the suspension or cessation of self-consciousness cannot be experienced or imagined *per se*. I cannot know what it is like not to be self-aware; since by definition one cannot be cognizant of such a state when one is in it. Barring accidents then, self-consciousness (the ground of human subjectivity) is understood as something ongoing, not as a once-off act. It has an ideal and repeatable character. Every protention is the expression of this understanding, anticipating as it does the repetition of the present moment of self-awareness. Reflective consciousness can be extensive and continuous because each moment contains the 'about to be' as well as the 'just gone'. Through protention and retention, past, present and future are connected in each individual moment of reflective awareness.

On Derrida's reading, Husserl is correct and prescient to recognize that each moment of self-consciousness involves retentions and protentions. But it is this very recognition that opens up a fissure in the claim that the now is something pure, unified and devoid of signification. It has been possible to present the now to consciousness only by setting it against something different, the immediately past now. It has been possible to present it as part of an unbroken unity only by anticipating the moment that will immediately succeed it. Consciousness of the selfsame, the now, always requires consciousness of the other, the not-now. Put another way, that which is different has to be held over and anticipated within the same so as to produce immediacy and continuity, the essential characteristics of a conscious subject. Derrida describes this retentional and protentional process as *autoaffection*. It constitutes rather than being constituted: 'This movement of difference is not something that happens to a transcendental subject; it produces a subject. Auto-affection is not a modality of experience that characterizes a being that would already be itself *(autos)*. It produces sameness as self-relation within self-difference; it produces sameness as the nonidentical' ([13.2], 92; [13.27], 82). Derrida is arguing against the idea of a self-identical now and hence of a primordial and self-contained subjectivity. To be itself the now has to point to moments beyond itself. Because they are actual forms of pointing, retention and protention can effectively be understood as signs of what has lapsed and what is pending. But is this admission of signs into the now of reflective consciousness also an invasion by indication? Taking retention on its own, one could argue that since it perfectly captures the past as it was in its own time, it is a fulfilled or expressive sign. In the case of protention, however, the situation seems different. The pending moment which I point to in the now will in turn point to another moment, and the cessation of this process is unimaginable—it could proceed to infinity. What I point to will never fulfil the present sign, because it will not itself be a self-referential plenitude. When one comes to look backwards, one sees that the situation was in fact the same. The present moment was itself anticipated in a previous moment, and that moment was also anticipated, right back to a primal moment of reflection that cannot be isolated because there was no antecedent reflection to identify it against. (The antecedent moment would be an unconscious trace hidden from view.) The most recent protention anticipating the immediate now passed over into a retention on the arrival of this present moment, and from this it can be concluded that both protention and retention

(one of which collapses into the other) are condemned to an unfulfilled and indicative function. The present moment cannot fulfil that which pointed to it in the past, and the pending moment will not fulfil that which is pointing to it in the present. Difference doubly contaminates the now. It only allows self-presence through a Janus-faced indication of an indefinite past and future. Presence is always already outside of itself, and so on without a definite end.

Derrida concludes his reading by adverting to a strangely prophetic passage from the first volume of Husserl's *Ideas* (1913). Husserl remembers walking through the Dresden Gallery and seeing a painting by Teniers. This represents a gallery of paintings, each of which represent further paintings in an endless regress. In this passage, as Derrida interprets it, can be glimpsed the fate of phenomenology. This raises the question of whether Husserl in some way reaches deconstruction *avant la lettre*. In the course of *Speech and Phenomena* Derrida speaks of Husserl's 'admirable' analysis of internal time consciousness, an analysis which he further characterizes as one of 'incomparable depth' ([13.2], 94 n. 1; [13.27], 84 n. 9). It seems strange that Husserl failed to see where this analysis was leading. The explanation, for Derrida, lies in the fact that the idea of unmediated or perfect presence is a pervasive and hidden prejudice carried forward from ancient times. The emphasis on the 'now' as an Archimedean point, the ground of immediacy and certainty, is one particular manifestation of this. So powerful is the prejudice that even Husserl, the first to provide the means for its circumscription, none the less remains under its sway. He stands on the very threshold of the deconstruction of the metaphysics of presence.

A brief overview of Derrida's career could well begin with the essays from his formative period in *Writing and Difference* (1967) [13.3; 13.28]. This collection includes the first article on genesis and structure and also 'Force and Signification' and 'Structure, Sign and Play', where the earlier analysis can be seen applied to modern structuralism. Whilst agreeing with the structuralist critique of a subjectivity that would be anterior to the world of signs, Derrida sees the general enterprise as misled in its tendency to construct closed sign-systems that are abstracted from time and change, and, having done this, to characterize these as transcendental realities that determine meaning in general. The dream of unearthing foundational structures centred on some fixed theme is a metaphysical illusion which sustains itself only by concealing the dynamic and ongoing process of constitution through which meanings emerge and mutate. The point at which this strategy is made evident is the point at which structuralism's fabrications begin to tremble and show their cracks. It is here that deconstruction takes its hold.

In 'Violence and Metaphysics', Derrida engages with the thought of Emmanuel Levinas. Characterizing the history of philosophy since Parmenides as a totalitarian wasteland, Levinas calls for an openness to the experience of the other that lies beyond the dominion of reason, whose logos has always been one of violence and power. The only ethical relationship to this other, or others, is one of infinite responsibility and respect. Whilst greatly admiring the approach of Levinas, Derrida argues that he does not pay due attention to Husserl's studies of intersubjectivity or to Heidegger's 'destruction' of those forms of thought that proceed from a determinate precomprehension of Being. Derrida also maintains that ordinary language and the philosophical discourse that proceeds from it cannot be escaped in the way that Levinas would like. Since the other

can only be revealed through discourse—the opening of peace as well as of war—the attempt to transcend this risks its suppression, which would result in the worst violence.

In 'Freud and the Scene of Writing', Derrida examines Freud's metaphor of the mystic writing pad, where the unconscious is likened to a text and the structures and layers of this text compared to forms of writing. This text, Derrida will argue, is a weave of signs based on lost traces which involves intervals spaced out in time just as in the world of conscious awareness. It would be one more ruse of reason to see the unconscious text as embodying primordial truths that could be brought to the surface and transcribed, like an original that is somehow reproduced. Even the most radical of critiques run the danger of confirming presence at a deeper level, and metapsychology is no exception. This theme of covertly reinstating what one seeks to reject recurs throughout the remaining essays and through the later Derrida.

O*f Grammatology* (1967) [13.4; 13.29] is an extended reworking of an article of the same name that Derrida originally published in two parts in 1965. The book incorporates many of the conclusions reached in *Speech and Phenomena,* and its purpose, according to Derrida, is to make enigmatic the concepts of proximity and of the proper that are included in the concept of presence. The deconstruction of these begins with the deconstruction of consciousness. Derrida explicitly generalizes the concept of the indicative sign to include anything that can possibly appear, whether it is 'originally' in consciousness or in the world of sense-experience. All 'present' things are internally constituted by variation of phonic and graphic marks or protentions and retentions. The manifest is what it is through being always ready set against irreducible absences. There is never a thing in itself that could come to glow in the luminosity of its own presence. Derrida rejects the belief that a sign or sign-system can eventually fall away before the naked object, like a veil that would drop from our eyes. This is the myth of the *transcendental signified,* of a terminus to the play of signs somehow outside that play. It recurs in various guises throughout the philosophical tradition, as God, or matter, or absolute knowledge, or the end of history. It remains a myth because it is never realized. In the absence of the transcendental signified we are left with the apparent limitlessness and pervasiveness of the play of signs. In this sense it can be held that everything is writing, with every instantiation of this general writing making up a text. (To give a crude example, the red sky in the morning is a set of signs written on the blank sheet of the sky. This text points to an indeterminate series of other events that will probably include a storm.) All meanings are inscribed in a text and point to other meanings in other texts. The world would be the most general text, though it is never closed or finished. The history of philosophy can be read as a sustained attempt to suppress such a seemingly endless play.

The ideal of the transcendental signified, according to Derrida, is the obverse side of *logocentrism,* which is the affirmation—in whatever form—of a pre-ordained order, of a univocal and proper meaning to all things that merely awaits discovery. Because it poses a threat to the communication of every supposed univocity, graphic writing has traditionally been relegated to the role of a dangerous and accidental supplement, with Rousseau providing the most notable example of such a strategy. Writing has been understood as something subsequent to a pre-given plenitude. But Derrida argues that there is another meaning to supplementarity which has been all but ignored in the

philosophical canon. The supplement is also that which is required to make up for a lack. If graphic writing were no longer seen as exterior and accidental, the way would be paved for the recognition of general writing as the weave of differences that inhabit and make possible all forms of presence. It is not by accident that Rousseau conceives of writing as an unhappy mischance, the root of dissemblance and impropriety. Writing has to be suppressed if he is to uphold the logocentric illusion of a prelapsarian state of nature. Rousseau most clearly demonstrates the inevitable violence of metaphysics, which equates propriety with pure presence through the debasement of writing.

The year 1972 saw the publication of three further books by Derrida: *Margins of Philosophy* [13.5; 13.30], *Dissemination* [13.6; 13.31] and *Positions* [13.7; 13.32]. *Margins* is made up of eleven articles written from 1967 on. Most of these are applications of a practice of reading whose theoretical grounding is effectively completed in the second article of the collection, entitled 'Différance'. This piece can also be read as a summary of the earlier works. Derrida presents *différance* as the development of Saussure's insight that in language there are only differences. It is also presented as an outcome of the important Heideggerian notion of ontological difference, the difference between Being and beings considered as such:

> It is the domination of beings that *différance* everywhere comes to solicit, in the sense that *sollicitare,* in old Latin, means to shake as a whole, to make tremble in entirety. Therefore, it is the determination of Being as presence or as beingness that is interrogated by the thought of *différance*. Such a question could not emerge and be understood unless the difference between Being and beings were somewhere to be broached. First consequence: *différance* is not. It is not a present being, however excellent, unique, principal, or transcendent. It governs nothing, reigns over nothing, and nowhere exercises any authority. It is not announced by any capital letter. Not only is there no kingdom of *différance,* but *différance* instigates the subversion of every kingdom…. Since Being has never had a 'meaning', has never been thought or said as such, except by dissimulating itself in beings, then *différance,* in a certain and very strange way, (is) 'older' than the ontological difference or than the truth of Being.
>
> ([13.5], 22–3; [13.30], 21–2)

Being is not a meaning that commands from a lofty height. It emerges from beings and they from it. In a similar way the intelligible needs the sensible and the natural the cultural. *Différance* is the productive movement of differing and deferring. Every concept is deferred in signifying a plenitude without realization and differed in gaining identity from that which it is not. *Différance* is not a concept, but that which makes concepts possible. It is not an essence, for it assumes a different form in each relation and does not exist before these.

In the third article, *'Ousia* and *Grammē',* Derrida examines a note by Heidegger concerning Aristotle on time. Aristotle first posed the problem of how Being can be determined as presence without determining time as external to substance, and hence as non-present and nonexistent (the no-longer and the not-yet). According to Derrida, Heidegger seriously neglects Aristotle's investigations. Furthermore, Heidegger's own

critique of 'vulgar temporality' succumbs—despite its significance—to the *aporia* or perplexity outlined by Aristotle. Authentic existence is characterized as primordial temporality and inauthentic existence as derivative temporality. In this opposition of the primordial and the derivative Derrida observes a covert reintroduction of Being as self-present substance.

'The Ends of Man' addresses the question of humanism, concentrating on Heidegger's critique of the general ideology. Derrida describes this critique as unsurpassed in the 'archeological radicalness' of the questions that it sketches. No metahumanist position can neglect the opening of these questions without being peripheral and secondary ([13.5], 153; [13.30],128). Heidegger wishes to transcend humanism so as to discover the proper essence and dignity of man, his *humanitas*. He seeks to move towards an understanding of man as an openness to the mystery of Being, one who will shepherd the true meaning of Being in the proximity of the near. Derrida regards this alternative as a subtle variant of traditional humanism. Heidegger's evocations of the proper and of proximity indicate a logocentric ideal, a real meaning of Being and of the self that can be epiphanically revealed to those who attain to the right attitude.

In *Dissemination* [13.6; 13.31] Derrida writes on Sollers, Mallarmé and Plato. In the best-known essay, 'Plato's Pharmacy', phonocentrism is traced back to the *Phaedrus* dialogue, where writing is condemned for endangering the truth of the living voice and reinstated as the inscription of eternal law in the soul. Writing is ambiguously characterized as poison and cure, this being its most charitable characterization in the western tradition.

The extended preface or 'Outwork' to *Dissemination* attacks the historical conception of the book as the best form of encapsulating authorial intentions in the graphic medium, since it has a definite structure of beginning, expanding and ending. Derrida reactivates his claim that the *différance* in all conscious activities usurps transparency and mastery in every form of every medium. The book is a concatenation of irreconcilable elements and forces from which meaning is onanistically disseminated or scattered to the four winds.

P*ositions* [13.7; 13.32] is a series of interviews held with Derrida so as to clarify his own project and its relationship with other intellectual movements. It can lay claim to being one of the more illuminating introductions to his thinking. According to Derrida, deconstruction is not a simple overturning of traditional philosophical prejudices or 'violent hierarchies'. It is best conceived as a double gesture of unseating the privileged motifs within texts (speech, nature, spirit, etc.) and then showing how the opposites on which they depend are sited within a subtext or shadow-text. The so-called master text is always haunted by a double that dislocates it rather than destroying it. *Différance* produces two texts or two ways of looking that are at once together and separate.

G*las* (1974) [13.8; 13.33] can be interpreted as a rather jarring example of deconstructive work in progress.[16] Hegel's discourses concerning God, law, religion and the family are presented on one side of each page and Jean Genet's somewhat different treatment of the same topics on the other. Derrida's running commentary oscillates somewhere between the two. The subtlety of this rather inaccessible performance may lie in showing that the reader always becomes a writer to extract sense. It could also be viewed as a once-off experiment in hyper-Joycean equivocity, for Derrida never again presents a work in this precise format.

With *Spurs* (1978) [13.10; 13.35], Derrida moves to a consideration of sexual difference. He focuses his attention on Nietzsche's strange denunciation of woman as the nexus of untruth and subversion, which on first sight might appear as one more rendering of Schopenhauer's misogynism. Derrida draws out of Nietzsche's cryptic remarks an anticipation of some of the themes in modern feminist criticism, since the latter was never noted for his love of the established order or of traditional conceptions of truth.

In *The Post Card* (1980) [13.12; 13.37], Derrida develops at length the theme—already seen at length in his work on the origin of geometry—of messages that fail to reach their destinations. In the course of readings of Freud, Lacan and Heidegger, he compares general writing to a telecommunications service that is quite capable of suffering hitches and breakdowns. The little postcard that is open to all symbolizes the fragility of meanings always already cast into space and time. Even messages that reach their addressees without too much delay can be misunderstood, whether they come from the subconscious, from the mystical contemplation of being, or from 'external' sources.

Most of Derrida's work since the late 1970s has concentrated on literature and its genre distinction with philosophy on the one hand and on matters ethical and political on the other. A good example of the first set of interests can be seen in *Parages* ('Regions') (1986) [13.15], which engages with the work of Maurice Blanchot. Derrida has also written on Ponge, Celan and Joyce.

The increased concern with ethics and politics first emerges in *The Ear of the Other* (1982) [13.1; 13.38], which was based on a colloquium held in Montreal in 1979. Derrida's remarks emerge out of considerations of the philosophical problems of autobiography and translation. He stresses that whilst *différance* undercuts authorial mastery and makes every interpretation a misreading, it does not destroy personal responsibility. The fact that statements and writings immediately take on a life of their own is an argument for eternal vigilance. One should at least attempt to foresee possible misinterpretations of one's works. Though the exercise cannot always succeed, it may minimize certain dangers inherent in inscription. These dangers have been well shown in the use that at least one ideology has made of the work of Nietzsche. We have to proceed as if every part of what we say and write could be taken out of context.

P*syché: Inventions de l'autre* ('Psyche: Inventions of the Other') (1987) [13.17] includes articles on Reconstructive methodology, sexual difference, racism and nuclear deterrence. In 'Racism's last word', written for an itinerant exhibition of art against apartheid, Derrida scrutinizes this very word. Apartheid is the appellation for one of the world's ultimate forms of racism. It signifies the violence of the talking animal that can make words discriminate rather than discern. Though it claims to represent a state of law derived from a natural or divine right, the day will come when this word will resonate in its own emptiness. Yet the collapse of what it signifies will be credited not just to the triumph of moral standards but to the laws of liberal economics that have come to determine this system as 'inefficient'. These laws of the market are another standard of calculation to be analysed.

In 'No Apocalypse, Not Now', Derrida attacks certain consequentialist assumptions in the logic of nuclear deterrence. The leading idea in the nuclear arms race has been that each advance in destructive capability will so impress the opposition as to make catastrophe more unlikely. Derrida notes that this assumes that the 'best intentions'

would always be 'correctly interpreted' by the other side. The seeming success of this strategy has also pleased the military-industrial complex. Expensive contracts can be made without any apparent increase in danger.

In the lengthy afterword to *Limited Inc*. (1988) [13.22; 13.44], the full record of Derrida's critique of the work of J.L.Austin and exchange with John Searle, Derrida tries to clarify questions concerning the aim and extent of the activity of deconstruction. Derrida states that although the themes of full presence and immediacy have been subjected to deconstruction, he has never argued for an untrammelled free-play of meaning. There can be a relative stability of meaning in texts; the point being made is only that this is not self-sufficient, immutable or indestructible. The double reading revealing a double text shows that the dominant meaning or interpretation of a text cannot live up to all its claims. In undoing conceptual hierarchies deconstruction seeks to achieve a more just balance. It does not suspend or reject the possibility of truth or of communication.

With *Memoires for Paul de Man* (1988) [13.21; 13.43] and *Du droit à la philosophie* (1990) [13.23], Derrida has included essays concerning the responsibilities and position of the intellectual in the modern or post-Enlightenment world.[17] He has maintained that the freedom of the academic world is only an abstract one, since the members of this world are effectively excluded from the fields of ethical and political decision-making. One of the crucial roles of the university in a technocratically managed society, according to Derrida, has been to provide a place where trouble-makers can be properly corralled and the compliant properly funded. As can be imagined, these analyses have not contributed greatly to Derrida's popularity amongst certain academics.

The most intriguing question that the essays in these books have raised—as with much of Derrida's work over the last few years—is that of the future direction of his project. Whilst his concentration on ethics and politics could be read as the unfolding of the hitherto unseen and positive aspects of deconstructive practice, it does not involve a clear advance on the theoretical groundwork already sketched in the 1960s. Furthermore, Derrida has not spoken of any departure from or revision of the existing body of texts. All the comments he has made on his work have been more or less explanatory in nature. It remains to be seen what new paths may be opened in the future by this most controversial of modern thinkers.

Timothy Mooney

NOTES

1 This section reworks certain arguments from the opening sections of *The Ethics of Deconstruction: Derrida and Levinas* [13.73].

2 This formulation implies, of course, a certain delusion on Rousseau's part, namely that he did not mean to say what he actually said and that what he actually meant to say is in contradiction with what is said in his text. Such a line of thought recalls Paul de Man's objections to Derrida in 'The Rhetoric of Blindness: Jacques Derrida's Reading of Rousseau', in *Blindness and Insight: Essays in the Rhetoric of Contemporary Criticism,* 2nd edn (London: Methuen, 1983), pp. 102–41, where de Man goes so far as to claim that 'Rousseau's text has no blind spots' (p. 139). Consequently, 'there is no need to deconstruct

Rousseau' *(ibid.)*. However, de Man continues, there is a profound need to deconstruct the established tradition of Rousseau interpretation which has systematically misread his texts. Thus, although de Man claims that Derrida is Rousseau's 'best modern interpreter' (p. 135), one who has restored 'the complexities of reading to the dignity of a philosophical question' (p. 110), Derrida is still blind to the necessarily ambivalent status of Rousseau's *literary* language (p. 136). Derrida fails to read Rousseau as *literature*. *Of Grammatology* is therefore an exemplary case of de Man's thesis on the necessary interaction of blindness and insight in the language of criticism.

In defence of Derrida, let me briefly say that despite de Man's many insights, *his* blindness to *Of Grammatology* consists in the fact that he reads the latter as a *critique* of Rousseau and not as a double reading. Derrida is no more speaking against Rousseau than he is speaking for him. Indeed, one might go so far as to say that the proper name 'Rousseau', whose texts Derrida comments upon, simply signifies the dominant interpretation (or, for de Man, misreading) of Rousseau; that of the 'époque de Rousseau' ([13.4], 145; [13.29], 97), an interpretation that sees Rousseau simply as a philosopher of presence, and which ascribes to him the fiction of logocentrism, a fiction that extends even to modern anthropologists like Lévi-Strauss, whose structuralism, it must be remembered, is Derrida's real target for so much of part two of *Of Grammatology*.

11 For a detailed discussion of closure in Derrida, see 'The Problem of Closure in Derrida', in [13.73], 59–106.

12 J.Derrida, 'Ponctuations: Le Temps de la thèse', in *Du droit à la philosophie* [13.23], 444, trans. K.McLoughlin, 'The Time of a Thesis: Punctuations', in A.Montefiore (ed.), *Philosophy in France Today* (Cambridge: Cambridge University Press, 1983), p. 38.

13 *Ibid.,* p. 446, trans. pp. 39–40.

14 Derrida, *Introduction à l'origine de la géométrie par Edmund Husserl* [13.1], trans. [13.26], 90. For a detailed outline of Derrida's *Introduction* and its influence on his later work see R.Bernet, 'On Derrida's "Introduction" to Husserl's *Origin of Geometry*' in J.Silverman (ed.) [13.70], 139–53.

15 Neither Derrida nor Husserl would ever deny the bare logical objectivity of a geometrical truth, that the three angles of a triangle make up two right-angles in two-dimensional space, for example. What they are claiming is that a particular objectivity is only philosophically significant when set within a wider context. For a more detailed explanation of this claim, see the *Introduction,* pp. 31–3 (trans. pp. 47–8).

16 Leavey has provided a concordance of references to Hegel in his *Glassary* (Lincoln: University of Nebraska Press, 1986).

17 Derrida's comments on the modern university clearly display the influence of Heidegger, as he would be the first to admit. An interesting comparison can be made between this aspect of Derrida's work and the more recent writings of the Austro-American philosopher Paul Feyerabend. In particular see the latter's *Farewell to Reason* (London and New York: Verso, 1987).

SELECT BIBLIOGRAPHY

The most exhaustive bibliography on the publications of Derrick is by A.Leventure, 'A Jacques Derrida Bibliography: 1962–1990', *Textual Practice,* 5:1 (spring 1991). Reprinted in amended form in D.Wood, *Derrida: A Critical Reader.* Another useful bibliography is by J.P.Leavey Jr and D.Allison, 'A Derrida Bibliography', *Research in Phenomenology,* 8 (1978):145–60. Also useful is the list given by P.Kamuf (ed.) in *A Derrida Reader: Between the Blinds* (New York and London: Harvester Wheatsheaf, 1991). Many of Derrida's articles have been published several times in French and English in a bewildering variety of books and journals. I have confined the following list to his published books.

Primary texts

13.1 *Introduction à l'origine de la géométrie par Edmund Husserl,* Paris: Presses Universitaires de France, 1962.
13.2 *La Voix et le phénomène: Introduction au problème du signe dans la phénoménologie de Husserl,* Paris: Presses Universitaries de France, 1967.
13.3 *L'Ecriture et la différence,* Paris: Editions du Seuil, 1967.
13.4 *De la grammatologie,* Paris: Editions de Minuit, 1967.
13.5 *Marges de la philosophie,* Paris: Editions de Minuit, 1972.
13.6 *La Dissémination,* Paris: Editions du Seuil, 1972.
13.7 *Positions,* Paris: Editions de Minuit, 1972.
13.8 *Glas,* Paris: Editions Galilée, 1974.
13.9 *L'Archéologie du frivole: Lire Condillac,* Paris: Denoël-Gonthier, 1976.
13.10 *Eperons: Les Styles de Nietzsche,* Paris: Aubier-Flammarion, 1978.
13.11 *La Vérité en peinture,* Paris: Aubier-Flammarion, 1978.
13.12 *La Carte postale: De Socrate à Freud et au-delà,* Paris: Aubier-Flammarion, 1980.
13.13 *L'Oreille de l'autre: Otobiographies, transferts, traductions: Textes et débats avec Jacques Derrida,* ed. C.Levesque and C.V.McDonald, Montreal: VLB Editions, 1982.
13.14 *D'un ton apocalyptique adopté naguère en philosophie,* Paris: Editions Galilée, 1983.
13.15 *Parages,* Paris: Editions Galilée, 1986. (A collection of essays translated in several English language texts.)
13.16 *Schibboleth, pour Paul Celan,* Paris: Editions Galilée, 1986.
13.17 *Psyché: Inventions de l'autre,* Paris: Editions Galilée, 1987. [A collection of essays translated in several English language texts.]
13.18 *De l'esprit: Heidegger et la question,* Paris: Editions Galilée, 1987.

13.19 *Ulysse Gramophone: Deux mots pour Joyce,* Paris: Editions Galilée, 1987. [Two essays translated in separate English language texts.]
13.20 *Signéponge,* Paris: Editions du Seuil, 1988.
13.21 *Mémoires pour Paul de Man,* Paris: Editions Galilée, 1988.
13.22 *Limited Inc.* Paris: Editions Galilée, 1990.
13.23 *Du droit à la philosophie,* Paris: Editions Galilée, 1990. [A collection of essays translated in several English language texts.]
13.24 *Le Problème de la genèse dans la. philosophie de Husserl,* Paris: Presses Universitaries de France, 1990. [A printing of Derrida's master's thesis.]
13.25 *L'Autre Cap,* Paris: Editions de Minuit, 1991.

CHAPTER 14
Postmodernist theory

Lyotard, Baudrillard and others

Thomas Docherty

INTRODUCTION

Philosophy has been touched by postmodernism. Philosophy, in the modern academy, is supposed to be the discipline of disciplines: it is philosophy which will be able to gather together, in one over-arching discourse, all the various micro-disciplinary problems and procedures dealt with in the differing and ostensibly unrelated fields of literature, medicine, law, politics and so on; and it is philosophy which will also set itself the task of explaining their necessary separations. Postmodernism has not 'challenged' philosophy; rather it has simply enabled an earthquake under its foundations; for postmodernism is most aptly situated precisely in the moment of the eradication of all foundational thinking. This, of course, makes it a fundamentally paradoxical exercise to 'define' postmodernism, for any definition would at once inherently seek the foundationalist status lexically integral to any description, while it would simultaneously discount in the semantic content of the definition the very possibility of such foundationalism. In what follows, therefore, I shall not so much 'define' postmodernism in philosophy as indicate what is at stake in the debates that have constituted the postmodern moment in our cultures.[1]

The term 'postmodern' was probably first consistently used by Arnold Toynbee in 1939; and it was prefigured in his writings in 1934 (that is, at around the date of the first recorded instance of the term's usage in Spanish, by Federico de Onis).[2] In *A Study of History,* Toynbee suggested that the 'modern' historical period had ended, at a date determined in his studies roughly between 1850 and 1918. Toynbee's historiography was a product of the late nineteenth-century desire to found a synoptic and universal history; and this desire was most easily accommodated in Toynbee's own individual work by the fact that his history approximates to the condition of a Christian theodicy. His task was to redeem humanity by discovering the trajectory of history to be a movement of separation from God and the eternal returns towards a theocentric and universalizing centre of meaning for the world. Secularity—history itself—becomes nothing more or less than a humble interruption in a fundamentally circular narrative structure, whose end is always already somehow contained in its beginning. This, of course, is reflected in much of the artistic literary production of the first decades of the present century in western Europe, where writers such as Eliot, Joyce, Mann, Proust and many others all experimented with the cyclical structures of history. For Toynbee and his kind, the facts of history would make sense in relation to a governing narrative structure which would be given and

legitimated in advance, since it is narrated fundamentally from the point of view of a monotheistic God.

Such a notion of history is indebted to conflicts which had their root in Enlightenment. As Hayden White points out, the Enlightenment broadly agreed with Leibniz's monadology in the sense that the philosophers of the Enlightenment subscribed to the view that there was an underlying unity or direction to human history. But the big difference between Leibniz and Enlightenment is that Leibniz thinks that this essential unity of humanity is simply immanent, whereas the philosophers of the Enlightenment view it as an ideal whose realization lies in the future, an ideal which is therefore, at best, imminent, or one which is

> *yet to be realized* in historical time. They could not take it as a *presupposition* of their historical writing, not merely because the data did not bear it out, but because it did not accord with their own experience of their own social worlds. For them the unity of humanity was an *ideal* which they could *project* into the future.[3]

Toynbee's invocation of a postmodern moment can thus be seen to accord with the idealist drive of Leibniz; yet it also acknowledges the necessarily future orientation of history. Toynbee can plainly see that the 'modern' moment is not yet a moment of a universal accord or harmony. In this, he is rather like the literary critic Erich Auerbach, who wrote his great study, *Mimesis,* while living in Turkey in flight from the Nazis. In that study, Auerbach poignantly and desperately attempts to discern, and to validate in the literary history of the western world, the idea of a shared humanity in which, 'below the surface conflicts' which ostensibly wedge us apart, 'the elementary things which our lives have in common come to light'.[4] Both these writers were writing under the sign of the Second World War, in which the ideology of a specific racial difference and disharmony momentarily, but triumphantly, was in the ascendant. Auerbach's answer to his predicament was to find solace in *aesthetic* harmony; Toynbee rather hypothesized a moment in the future, a 'post-modern' *political* moment, when history and humanity can be properly redeemed.

The word 'postmodern' is thus characterized, from its very inception, by an ambiguity. On the one hand, it is seen to describe a historical period; on the other, it simply describes a desire, a mood which looks to the future to redeem the present. This ambiguity is at the core of a tension between postmodernism as an aesthetic style and postmodernity as a political and cultural reality.

This is an instance of one of the dominant philosophical concerns responsible for shaping the question of the postmodern: what is the proper relation in our time between the aesthetic and the political? The particular intimacy of the relation between aesthetics and politics in postmodernism is apparent even from the earliest considerations of the question. Leslie Fiedler characterized the emergence of new aesthetic priorities in the novel during the 1960s as a 'critical point' in which new attitudes to time were developed; and such attitudes, he claimed, 'constitute…a politics as well as an esthetics'.[5] In the light of this, it is interesting to note that two of the foremost thinkers in the field of postmodernism, Fredric Jameson and Jean-François Lyotard, both write

equally fluently and influentially on aesthetic culture and on political practices; and, more importantly, they have consistently pondered the relation between these hymeneally-linked activities. A deep formative influence lying behind much of the contemporary debate, as is now perhaps obvious, is the legacy of the Frankfurt school, perhaps most especially the work of Adorno, to which I shall return. For present purposes, the single salient fact is that aesthetic postmodernism is always intimately imbricated with the issues of a political postmodernity, even if postmodernism and postmodernity may not always themselves coincide.

As a result of the legacy inherited from Frankfurt, the question of the postmodern is also, tangentially at least, an issue of Marxism. Marxism, in placing the labouring body at the interface between consciousness and material history, is the necessary explanatory and critical correlative of a modern culture whose technology (in the form of an industrial revolution) divides human knowledge or consciousness from human power or material history. But the continuing revolutionary shifts within capitalism itself have necessitated in recent years a marked and vigorous self-reflection on the part of Marxism. In Habermas, for instance, Marxism has taken 'the linguistic turn', in arguments for a continuation of the emancipatory goals of Marxist theory and practice under a revised rubric of 'communicative action'. Habermas's faith in the continuing viability of a vigorously self-revising Marxism is shared by Jameson, who models his own version of 'late Marxism' to correspond with Mandel's descriptions of 'late capitalism'.[6]

A key date here, of course, is 1968. This is not only a moment which could be described as the high point of 'grand theory' and of the emergence of a poststructuralist challenge to what had become by then the grand structuralist orthodoxies; it is also the moment of a critical political failure. The seeming availability of a revolution which brought workers and intellectuals together all across Europe represented a high point for a specific kind of Marxist theoretical practice. But when these revolutions failed, many began, at precisely that moment, to rethink their commitments to the fundamental premises of Marxist theory. Simultaneously, most other erstwhile dominant philosophical trajectories (the phenomenological tradition; the insistence on the centrality of Hegel via Kojève; the entire 'history of western thought') came under suspicion and revision.

Rudolph Bahro and André Gorz began, from an economistic perspective, to rethink issues of growth and sustainable development. Their emergent ecologism coincided neatly with the 'imaginative' aspects of 1968, and Cohn-Bendit began his own movement from red to green. Kant began to assume the same kind of position of centrality once occupied by Hegel. Feminism and deconstruction both criticized the monolithic aspects of the institutions of western thinking. These all coincided neatly with the aftermath of the Algerian and other colonial crises, and with the growing awareness of the issues relating to post-colonialist cultures. The developed countries began to question not only the desire of the underdeveloped countries for the same levels of consumerist technology as those enjoyed by the First World, but also the reliance of that First World upon exhaustible planetary resources.

For many European thinkers who were now coming to question the fundamental grounds of their intellectual activities and philosophies, Marxism now began to appear to be part of the problem, especially in its assumption of the desirability of human mastery over nature. The emerging Green movement of this period moved closely to a post-

Marxism which was sceptical of Enlightenment: sharing the emancipatory ideals and the desire for the fullest possible enjoyment of human capacities, but tempering that with the idea of a necessary cohabitation between humanity and the rest of nature. A postmodern world needed a post-Marxist politics. Gramsci began to assume a prominent position in this thinking, and the notion of hegemony replaced that of class as a fundamental political category. A new political pluralism became possible precisely at the moment when technology, as Lyotard indicates, had made it possible for the multinational companies to homogenize and unify their forms of control. Yet underneath the increasingly homogenized capitalist world, the play of local forces continues to pose the threat of a disruptive pluralism which capitalism must now police if it is to sustain itself. For those forces to be activated, all we require is the release of something inimical to capital, the release of something which cannot be inserted into or accommodated within a capitalist economy. The radical, central philosophers at this moment made their revolutionary investment in the body and in libidinal desire.

Perhaps the most extreme re-thinking of Marx began with the socalled 'philosophy of desire' in texts such as Lyotard's *Economie libidinale* (1974; complete translation not available) or in the work of Deleuze and Guattari in their *Capitalisme et schizophrénie* (1972, 1980; translated 1984, 1987). This work led Lyotard and Deleuze to the position where they favour the supervention of a micropolitics which will attend to the local and the specific without recourse to some grand programme or macropolitical theory such as Marxism, psychoanalysis or evolutionary progress to legitimize actions taken at the local level. Practice is now valid—that is to say, it becomes an 'event'—only when it is unanswerable to, or when it is actually disruptive of, a totalizing 'grand theory'.

The most explicit attack on fundamental Marxist theory, and specifically on its underlying category of 'production' is fully developed in Baudrillard's *Le Miroir de la production* (1973; translated as *The Mirror of Production* 1975), a work which set Baudrillard firmly on a trajectory away from any form of classical Marxism. His work since has increasingly sustained a problematization of the oppositionalist impetus inscribed in Marxist theory. For Baudrillard, opposition to a dominant force is always already inscribed in the structure which holds that dominant force in power. The oppositional energy is diverted and recharged to the account of the dominant force: opposition works like inoculation. Marxism inoculates capital, the better to sustain it: 'critical' or 'oppositional' thinking is, as it were, the last refuge of the bourgeois, who is condemned to go through the motions of theoretical opposition while simultaneously sustaining the historical status quo.

Theory, by which I here mean any critical practice which makes a philosophically foundational claim, enters into crisis itself in the wake of 1968. Not only has knowledge become uncertain, but more importantly the whole question of how to legitimize certain forms of knowledge and certain contents of knowledge is firmly on the agenda. No single satisfactory mode of epistemological legitimation is available. Even if one were, the very Subject of consciousness has, as a result of deconstruction and psychoanalysis, also been thrown into doubt. Postmodernism is shaped and informed by these crises in epistemology, in ontology, in legitimation and in the Subject.

In what follows, I shall firstly outline briefly the intellectual trajectory of two thinkers whose work has shaped much of the debate over postmodernism: Jean-François Lyotard

and Jean Baudrillard. I shall then substantively address the issue of the Enlightenment and its contested legacies. This leads into a necessary reconsideration of the question of politics, specifically under the rubric of a theory of justice. In conclusion, I shall draw together the characteristics of postmodern philosophy under the sign of what might be called, in contradistinction to Leibnizian Optimism, a 'new pessimism' distinguished not by sadness but by stoicism.

TWO PARADIGMATIC THINKERS

Jean-François Lyotard

Lyotard moved to the centre of debates around postmodernism in the late 1970s when he defined *The Postmodern Condition* in terms of an 'incredulity toward metanarratives'.[7] By this, he meant that, in the contemporary world, it had become difficult to subscribe to the great narratives which had previously conditioned existence, be they narratives of salvation as in the various religions, or of emancipation as in Marx, or of therapy as in Freud, and so on. Postmodernism was defined in terms of an anti-foundationalism; it was a mood and not a period; and it was characterized by a pragmatic and experimentalist attitude. Like the artist, the postmodern philosopher was to 'work without rules in order to formulate the rules of what will have been done' *after the event*:[8] that is to say, thinking was to be radically experimental and ostensibly undirected in order to allow for the unpreprogrammed, for the unforeseen, to take place.

This led Lyotard to ponder two key theoretical principles: that of the 'event'; and that of 'justice'.[9] An 'event' occurs when 'it happens' without the 'it' having any specific identity. Such an identification of 'what' happened can only happen when the event is inserted into a determining structure which will assign a meaning to the happening and a substance to it. An 'event' is, as it were, a happening laid bare, devoid of a Subject, devoid of—or, better, prior to—an assigned significance. For Lyotard, the honour of thinking can itself only occur when thinking is 'eventful', when thinking is of the status of an event.

Thought thus has little to do with the accumulation of 'knowledges' whose significance can be arrayed and arranged in hierarchical orders and sequences, initially placed in repositories of knowledge such as libraries and museums, but increasingly in our time stored in ostensibly less material but equally reified form on microchips or on computer discs.

For Lyotard, one effect of this is the necessity to wage war on all forms of totality. He argues that any 'grand narrative' or foundational theory necessarily tends to homogenize the absolute heterogeneity and specificity of singular events, thereby robbing the event of its full ontological or historical status and, more importantly for a philosopher, denying the possibility of genuine thinking. Further, he argues that such totality most often articulates itself under the form simply of consensus. Here, he explicitly set himself apart from a thinker such as Jürgen Habermas, who argues that, given the lack of any prior foundational philosophy upon which to build a rational society, individual Subjects must strive collectively or mutually to attain a rational consensus which will enable the

formulation of (at least provisional) values against which individual acts can be judged. In other words, a practical social theory is to be based upon rational discourse and the disinterested pursuit of the better argument by a community. Lyotard argues that the consensus thus reached is illusory, for it is necessarily founded upon a covert violence between the participants in the dialogues, in which the discourse of one Subject will always find itself degraded in and by the discourse of the other. There is no consensus without the covert exercise of an imperialist power, according to Lyotard, who therefore prefers the pursuit of paralogy over consensus.

In order to maintain thinking at the status of the event, it becomes important to bear witness to what Lyotard calls the 'differend'. A differend occurs when, in a dispute between two parties, the rules of conflict which bring them into their opposed positions are made in the idiom of one party while the wrong from which the other suffers simply does not figure and cannot be recognized in that idiom. That is, the fundamental clash is one of language-games; the language-game of each party to the dispute simply cannot accommodate the terms of the wrong suffered by the other; and further, there is no common language to which a 'neutral' appeal can be made to facilitate an adjudication between the two parties.

Here we enter the second specific realm of Lyotard's concern: justice. As with knowledge, justice or judging too must become, for Lyotard, an event rather than a substance. Given that we should abandon the metanarrative, or theory, we now have no grounds upon which to make our judgments, be they aesthetic, ethical, political or whatever. Yet we must judge, as a simple condition of living. For Lyotard, we must bear witness to the differend and learn to judge without criteria. This he relates to the Kant of the third Critique, where a fundamental distinction is made between determining judgment and reflective judgment. Determining judgments are made in conformity to a rule; reflective judgments are those where we lack any formal guiding principle, as in aesthetics. Lyotard urges the prioritization of the latter, for it is only by making judging and thinking reflective—and thereby 'eventful' —that we will attain to the postmodern mood; and it is only that way that we can avoid the tacit political violence which dominates and informs our modes of philosophy and of social being.

Jean Baudrillard

Baudrillard, like Lyotard, began his career on the political left. But in *The Mirror of Production,* he began his trajectory steadily away from any recognizable Marxism and towards an extremely different position indeed. Fundamentally, Baudrillard began by arguing that Marx was not Marxist enough; that in the attempt to confound political economy, Marx simply could not manage to escape the form 'production' and the form 'representation' which shape political economy. Marxism is thus tainted by a complicity with capitalism, argued Baudrillard. He then began himself to try to find a way out of this by insisting that the world is not 'pro-duced' but 'seduced': seduction, he claimed in *De la séduction,* was logically prior to production. Seduction is not simply sexual: it is rather any mutual interplay of forces of attraction and repulsion. It thus can have no paradigmatic form and veers into a multiplicity of social practices, none of which can assume a position of centrality, normativity or dominance. By this point, Marxism has not

been modified as much as entirely abandoned.

Baudrillard began to indicate that Marxism had become part of the problem rather than part of the cure for a society in any case. He suggested that in any given system (such as a capitalist one) which is characterized by efficiency, the possibility of opposition to the system has to be controlled internally if the system is to persist. The single best way of controlling opposition is, of course, by accommodation. Hence, using a medical analogy, Baudrillard argued that every system generates localized 'scandals' which ostensibly throw the system entirely into disrepute—but which operate rather like an inoculation against disease. Thus, for instance, Watergate was a scandal to the office of the President of the USA; but it was a scandal which 'purified' the office by vilifying its temporary occupant; it thus enabled the possibility of that now 'purged', 'incorruptible', office being inhabited very soon after by Ronald Reagan, whose folly, lies and obvious insincerity far outstripped anything of which Nixon seemed capable. Similarly, capitalism needs and thrives on Marxism; masculinism and patriarchy need feminism if they are to strengthen themselves; racism requires anti-racist legislation; and so on.

This somewhat desperate scenario provokes Baudrillard into his most radical claims, and into a position usually described as 'nihilist'. The principle of reality itself, he argues, is defunct. At an early stage in his career, when he concentrated his attention on consumer society, Baudrillard rapidly realized not only that consumption was the new structure of power in the social, but also that something had happened to the very materiality of the object of consumption. He argued that the object as signifier was more important than the object as referent. In other words, classical 'use-value' had been replaced not just by 'exchange-value' but by what might be called 'signifying-value', or the value of the object as a sign. The referent—the 'real' world—began simply to disappear in Baudrillard's theoretical thinking.

When allied to his thinking on negation or criticism as a form of therapeutic inoculation, this has far-reaching consequences. Baudrillard is now able to argue that Disneyland, for example, is there as an arena of fantasy in order to generate the belief that the rest of the USA, everything 'outside' Disneyland, is 'real'. In fact, Baudrillard argues, it is the rest of the USA which is now living entirely at the level of fantasy. Meanwhile 'the real' has disappeared, or has been overtaken by simulacra of the real. Thus he felt able to claim, for instance, that, in a specific sense, the Gulf War of 1990 'did not take place'. Baudrillard indicates that technology has now made it possible for us to reproduce the real in a 'more' real form than the 'original'; and historical events for us now are only real once they have been mediated, usually by television. If we are to make any genuine philosophical or political engagement in this state of affairs, it has to be done by attending not to specific aspects of the real but rather to the very principle of reality itself.

ENLIGHTENMENT AND ITS LEGACIES

A major source for the contemporary debates around the postmodern is to found in the work of the Frankfurt school, and perhaps nowhere more precisely than in the text proposed by Adorno and Horkheimer in 1944, the *Dialectic of Enlightenment,* a work 'written when the end of the Nazi terror was within sight'. This work prefigures some of

Lyotard's later scepticism over Enlightenment; and it also seriously engages the issue of mass culture in ways which influence Gorz's thoughts on the 'leisure merchants' of contemporary capitalist societies. It is worth indicating in passing that it is Adorno and Horkheimer, and not Lyotard, who propose that 'Enlightenment is totalitarian':[10] the vulgar characterization which describes contemporary German philosophy as pro-Enlightenment and the French as anti-Enlightenment is simplistic and false.

Enlightenment aimed at human emancipation from myth or superstition, and from an enthralled enchantment to mysterious powers and forces of nature. Such emancipation was to be effected through the progressive operations of critical reason. According to Peter Gay, 'The Enlightenment may be summed up in two words: criticism and power':[11] criticism would become creative precisely by its capacity for empowering the individual and enabling his or her freedom. Why would Adorno and Horkheimer set themselves in opposition to this ostensibly admirable programme? Why do they argue that 'The fully Enlightened earth radiates disaster triumphant'?[12]

The problem lies not in the theoretical principle of Enlightenment but in its practice. In the desire to contest any form of animistic enchantment by nature, Enlightenment set out to think the world in an abstract form. Consequently, the material content of the world becomes a merely formal conceptual set of categories. As Adorno and Horkheimer put it: 'From now on, matter would at least be mastered without any illusion of ruling or inherent powers, of hidden qualities. For the Enlightenment, whatever does not conform to the rule of computation and utility is suspect'.[13] In a word, reason has been reduced to *mathesis:* that is, it has been reduced to a specific *form* of reason. More importantly, this specific inflection of reason is also now presented as if it were Reason-as-such, as if it were the only valid or legitimate form of rational thinking. But Adorno and Horkheimer share a fear that, in this procedure, reason has itself simply become a formal category, which reduces or translates the specific concepts of material realities into rational concepts, or into a form amenable to mathematization. Reason becomes no more than a discourse, a language of reason (the codes of mathematics), which deals with the 'foreign' matter of reality by translating it into reason's own abstract terms; and something—the 'event', non-conceptual reality itself—gets lost in the translation. As Adorno and Horkheimer have it: 'The multiplicity of forms is reduced to position and arrangement, history to fact, things to matter.'[14] A mathematical consciousness thus produces the world, not surprisingly, as mathematics. So a desired knowledge of the world is reduced to the merest *anamnesis,* in which a consciousness never cognizes the world as it is, but rather *recognizes* the world as the proper image and correlate of the consciousness itself. Enlightenment thus serves only the self-Identity of the Subject of consciousness.

'Emancipatory' knowledge turns out to involve itself firmly with a question of power, which complicates and perhaps even restricts its emancipatory quality. Knowledge, conceived as abstract and utilitarian, as a mastery over a recalcitrant nature, becomes characterized by power; as a result, 'Enlightenment behaves toward things as a dictator toward man. He knows them in so far as he can manipulate them. The man of science knows all things in so far as he can make them.'[15] Knowledge is hereby reduced to technology; and that in nature—the 'event'—which is unamenable to the formal or conceptual categories of such mathematical knowledge simply escapes consciousness.

Yet the Subject believes itself to have captured, dominated and conceptually controlled the event; for it can determine the *meaning* of the event. There is thus only the *illusion* of power over nature; and yet there is a more important dividend of power here: the Subject endowed with Enlightenment 'knowledge' has a power over the consciousness of others who may be less fluent in the language of reason. Knowledge is thus caught up in a dialectic of mastery and slavery in which the victim is not a dominated and overcome nature but rather other overwhelmed human individuals. Accordingly, knowledge such as this cannot be purely characterized by disenchantment and emancipation. Enlightenment does not simply produce a disenchanted knowledge of the contents of the material world; rather, it produces a formally empowered Subject of consciousness, a Subject which exerts its power in the discourse of reason, in a language-game. From now on in philosophy—and this is what will be characterized as the 'modern' philosophy from which postmodernism wishes to escape—to know is to be in a position to enslave, or, as Lyotard will argue, 'what was and is at issue is the introduction of the will into reason'.[16]

What is thus at issue is a confusion between the operations of a pure reason on the one hand and a practical reason on the other: a confusion between theory and practice, between *gnosis* and *praxis*. This is an old Aristotelian distinction which has resurfaced precisely at the moment when many thinkers are becoming suspicious precisely of theory itself. Twentieth-century literary criticism, the field in which much of the postmodern debate has been fought out, presents us with a series of attempts to yoke together theory and practice. Language, for instance, is often seen not as something which merely runs alongside and parallel to the 'real' events of material history: rather, it is consistently secularized, realized as itself a historical event. This is so all the way from J.L.Austin's speech-act theories of performative linguistics, through various advocates of the idea of 'language as symbolic action' (Kenneth Burke, R.P.Blackmur and others), and all the way on to the contemporary revival of Jamesian and Deweian pragmatism in the thinking of Rorty, Fish and others.[17] These are all attempts to bring together the epistemological function of language with the ontological event of linguistic activity. And in this regard, twentieth-century literary criticism can be seen to be wrestling with one major and fundamental issue: the perceived rupture between the realm of language and the realm of Being, a rupture articulated most vigorously by those readers of Saussure's *Course in General Linguistics* who prioritize above all else the arbitrariness of the relation between the linguistic signifier and the conceptual signified. By inserting the cognitive activity of a real historical reader between the text and its epistemological content, critics such as Fish, Jauss, Iser and others tried to circumvent the threatened split between, on the one hand, the structure of consciousness (i.e., the conceptual forms in which a consciousness appropriates the world for meaning) and, on the other, history (the material content of a text which may—and indeed, according to Fish, *must*—disturb such formal structures).

In philosophical terms, what is at stake here is an old Kantian question regarding the proper or adequate 'fit' between the noumenal and the phenomenal. Kant was aware that the world outside of consciousness does not necessarily match precisely our perceptual cognitions of that world; and in the *Critique of Pure Reason* he argued that it was erroneous simply to confuse the two. The two elements of signification being confused were distinguished by Frege as 'sense' and 'reference'; and it is a distinction similar to this which was maintained by Paul de Man, who argued that such a confusion is precisely

what we know as 'ideology': 'What we call ideology is precisely the confusion of linguistic with natural reality, of reference with phenomenalism.'[18]

De Man's concern was to ensure that literary criticism made no premature assumptions of the absolute validity of reference; and in this he simply followed the deconstructive practice of maintaining a vigilant scepticism about the legitimacy or truth-contents of any linguistic proposition made about those aspects of the real world that could properly be called 'non-linguistic'. He was aware that the premature assumption that the world was available for precise, 'accurate' or truthful linguistic formulation was itself an assumption not only grounded in but fundamentally demonstrative of ideology. But this, of course, is simply a reiteration of Adorno and Horkheimer in their complaint about the assumption made by (mathematical) reason that the world is available for rational comprehension. It should now be clear that the fundamental burden of the *Dialectic of Enlightenment* is that Enlightenment itself is not the great demystifying force which will reveal and unmask ideology; rather, it is precisely the locus of ideology, thoroughly contaminated internally by the ideological assumption that the world can match—indeed, can be encompassed by—our reasoning about it, or by the attendant assumption that the human is not alienated by the very processes of consciousness itself from the material world and events of which it desires knowledge in the first place. Enlightenment, postulated upon reason, is—potentially at least—undone by the form that such reason takes.

For Adorno and Horkheimer, this argument assumed a specific shape recognizable as an abiding question in German philosophy from Kant to Heidegger. What worried Adorno and Horkheimer was that under the sign of Enlightenment, the Subject would be capable of an engagement with the world in a manner which would be 'rational' only in the most purely formal (and thus vacuous) sense of the word. That is, they were anxious that what should be a properly *political* engagement which involves the Subject in a process called intellection or thinking could be reduced to a ritual of thinking, to a merely formal appearance of thinking which would manifest itself as a legitimation not of a perception of the world but of the analytical modes of mathematical reason itself. The political disturbance of the Subject proposed by an engagement with a materially different Other (i.e., the Subject as transformed and transfigured through an 'event') would be reduced to a confirmation of the aesthetic beauty and validity of the process of mathematical reason itself, a reason whose object would thus be not the world in all its alterity but rather the process of reason which confirms the Identity of the Subject as an identity untrammelled by the disturbance of politics, an amorphous identity predicated on a narcissism and uninformed by any real event. In short, the Subject would be reduced to an engagement with and confirmation of its own rational processes rather than being committed to an engagement with the material alterity of an objective world.[19]

The 'aesthetic engagement' with the world might be characterized as follows: the structure of consciousness determines what can be perceived, and processes it in accordance with its own internal logic, its own internal, formal or ritualistic operations of reason. There is thus a ritual or appearance of engagement with the material world only. 'Political engagement' would be characterized by the rupture of such ritual, by the eruption of history into the consciousness in such a way that the aesthetic or formal structures of consciousness must be disturbed, reconfigured, rearranged. Enlightenment's commitment to abstraction is seen as a mode of disengagement of the ideological,

opinionated self: abstraction is itself meant to address precisely this problem. But it leads, according to Adorno and Horkheimer, not to a practice of thinking but rather to the ritualistic form of thought; it offers a form without content. Adorno and Horkheimer fear that it is precisely when Enlightenment addresses the political that it in fact most successfully evades the political; that Enlightenment is Idealist precisely when it pretends to be fully materialist.

One twentieth-century legacy of Enlightenment is the so-called 'Copernican revolution' proposed initially by structuralism and semiotics. In the wake of Roland Barthes, the world became an extremely 'noisy' place: signs everywhere announced their presence and demanded to be decoded. Such decoding was often done under the aegis of a presiding formal structure, such as myth in anthropology (Lévi-Strauss), desire in psychoanalysis (Lacan), or grammar in literature (Genette, Greimas, Todorov). In semiotics, it is always important to be able to discover a kind of equivalence between ostensibly different signs: this is, in fact, the very principle of decoding or of translation which is at the basis of semiotic analysis. But as Adorno and Horkheimer indicate: 'Bourgeois society is ruled by equivalence. It makes the dissimilar comparable by reducing it to abstract qualities.'[20] Such abstraction must wilfully disregard the specificity of the material objects or events under its consideration: 'Abstraction, the tool of enlightenment, treats its objects as did fate, the notion of which it rejects: it liquidates them.'[21] The semiotic revolution—a revolution which frequently masqueraded as a political, emancipatory heir of Enlightenment, but a revolution whose content was only at the level of the abstract sign and thus at the level of an aesthetics denuded of politics—is, like Enlightenment, irredeemably bourgeois in the eyes of the postmodernist, for it is irredeemably caught up in a philosophy of identity which negates material and historical reality in the interests of constructing a recognizable Subject of consciousness as a self-identical entity.

When postmodernism rigorously questions the tradition of a selfconsciously 'modern' Enlightenment philosophy, it does not do so in the interests of nihilism or irrationality. Postmodernism indicates rather (as did Foucault) that Enlightenment reason may not itself be entirely reasonable.[22] Further, postmodernism returns to the great Kantian questions: how might we know the alterity of a material reality; how might we validate or legitimize that knowledge?

The *Dialectic* was written in a profound awareness of the material and historical realities of fascism and of the Nazi atrocities. It is a text which inserts itself in a specific tradition of philosophical and ethical tracts which ask for an explanation of the presence of evil in the world. This tradition was properly inaugurated in the modern world by the debates around Leibniz and Optimism. Optimism is based on the idea that nature is a Leibnizian monad, and that there is a great unifying chain in nature which links, in a necessary conjunction, all the ostensibly random and diverse elements of a seemingly heterogeneous and pluralistic world. Much more important for our purpose is the observation that Optimism must be based upon a specific idea of *progressive time* which challenges the meaning of events. It argues that what appears 'now' to be a local evil will be revealed 'in the fullness of time' as something which essentially serves the realization of a greater good. As Voltaire's Pangloss has it in *Candide,* 'All is for the best in the best of all possible worlds'; or, as a less comic predecessor, Milton's Satan, has it: 'Evil, be

thou my good.'[23] History would reveal the immanent goodness in the most apparently evil acts; under the sign of a homogeneous and monadic eternity, the heterogeneous and secular would be redeemed.

In a sense this philosophy is a precursor of some contemporary theoretical principles; and it foreshadows directly the great (and perhaps final) flowering of a modernist thought in deconstruction. According to Optimistic philosophy, the meaning of an event is not immediately apparent, as if it were never present-to-itself: its final sense—to be revealed as the necessity of goodness—is always deferred (to be revealed under the sign of eternity), and is thus always 'different' (or not what it appears to be to the local eye caught up in the event itself). The major difference between deconstruction and Optimism is that Optimism believes that the final sense lies *immanently* within an event, whereas deconstruction eschews any such 'immanentist' ideas as metaphysical. Yet the trajectory underpinning both is the same in that they share fundamentally and tacitly an investment in the notion of a 'progressive enlightenment': the passage of time is invested with the idea of *progress*.

Optimism was buried, of course, with the buildings under the earthquake in Lisbon on 1 November 1755. But at that time a different idea of progress in history arises. After 1755, progress is characterized as a gradual emancipation from the demands of the sign of eternity. The secularization of consciousness became a necessary precondition for the possibility of an ethics: that is to say, the ethical is increasingly determined by the philosophically rational, or the good is determined by the true. Hans Blumenberg in his *The Legitimacy of the Modern Age,* offers eloquent testimony to the inflection this gives to philosophy and to truth. Traditionally, the pursuit of truth had been pleasurable, eudaemonic; from now on, the absoluteness of truth, and correspondingly its ascetic harshness, becomes a measure of its validity: 'Lack of consideration for happiness becomes the stigma of truth itself, a homage to its absolutism.'[24] Pain legitimizes knowledge.

There arises thus the possibility—and Kantians would argue the necessity—of separating the realm of facts from the realm of values: neither can legitimately be derived from the other, neither facts from values nor values from facts. Optimism has proceeded on the grounds that these were intimately conjoined; and it followed that the progressive movement from evil to good was seen as inevitable. But once epistemology is separated from ethics, the whole idea of historical progress is itself called into question: no longer do we know with any certainty the point towards which history is supposedly progressing. In the wake of this, humanity becomes enslaved not to the enchantments of myth but rather to the necessities of narrative, for humanity has embarked upon a secular movement whose teleology is uncertain, whose plot is not inherently predetermined by values or by an ethical end.[25]

This critique of progress returns in the twentieth century; and is acentral component of a postmodernist mood. The paradigmatic example comes in architecture, where there has grown a resistance to the 'modernist' idea that all buildings must be innovative in aim and design. As Jencks and Portoghesi have suggested, it is possible to relearn from the past, to develop a 'new classicism' or simply to engage with an abiding 'presence of the past'.[26] The result is—in principle if not always in practice—a heterogeneous juxtaposition of different styles from different architectural epochs as a putative response

to the homogenizing tendency of the so-called 'international style'. This argument leads to two interrelated consequences. The first is that lived space is inhabited by a complicating sense of historical time.[27] More importantly, there grows an awareness in architecture and urban planning in general that the local traditions of a place should be respected in all their specificity, while at the same time these local traditions may be opened to a kind of criticism by their juxtaposition with styles from other localities and from different traditions.[28] This is a localism without parochial insularity: a revalorization of the 'periphery' without the need for a determining 'centre'.

Probably the greatest and most-cited description of the postmodern coincides nicely with this architectural scepticism regarding inexorable progress. In philosophy, Lyotard argued that the postmodern mood was characterized by an 'incredulity towards metanarratives'. In an argument which he subsequently described as 'overstated', Lyotard argued that it was becoming increasingly difficult to subscribe to the great—and therapeutically Optimistic—grand narratives which once organized our lives.[29] What he had in his sights were the great totalizing narratives, great codes which in their degree of abstraction necessarily deny the specificity of the local event and traduce it in the interests of a global homogeneity or a universal history. Such 'master narratives', as they subsequently came to be called, would include the narrative of emancipation via revolution proposed by Marx; the narrative of psychoanalytic therapy elaborated by Freud; or the story of constant development and adaptation advanced under the rubric of evolution by Darwin. Such narratives operate like Enlightenment reason: in order to accommodate widely diverging local histories and traditions, they abstract the meaning of those traditions in a 'translation' into the terms of a master code, thereby violating the specificity of the local and rendering real historical events unrecognizable. As metanarratives, they also become coercive and normative. In the interests of respecting the heterogeneity of the real, and (more importantly for Lyotard) in the interests of maintaining the possibility of thought, of philosophy, we must wage war on such totalizing prescriptive grand narratives. Lyotard's debt to Adornian critical theory is obvious here.

This new pessimism with regard to the idea of historical progress was foreseen by Walter Benjamin, another great source for much postmodern thinking. In his famous seventh thesis on the philosophy of history, he indicates a specific scepticism regarding history which has been picked up and thoroughly developed in postmodernism. His famous words in that thesis—'There is no document of civilization which is not at the same time a document of barbarism'—prize open the historical document—and, by extension, the event itself—to an internal instability and mutability.[30] Postmodernism has enlarged on this to the extent that it challenges the very notion of there being any universal history at all. It is important to be clear on this: postmodernism does not deny history; rather, it denies that there is only *one* history. For Lyotard, a universal history implies a single transcendent Subject position from which the history might be recuperated, appropriated, recounted or narrated: that is to say, universal history is predicated on monotheism. In place of this, Lyotard advocates the pluralism of paganism: multiple gods, multiple histories, no transcendence.[31] Any singular event can be inserted into any number of histories, each presided over by a different force or power; and its value—its essence—will depend upon the contradictions and incoherence involved in our

necessarily considering the event from such a pluralist perspective. In the simpler terms which Benjamin had in mind, the singular event of a battle, say, is different when one is the victim and when one is the victor: postmodernism would ask us to think the narratives proposed by both such positions simultaneously.

'Modernity' itself is increasingly seen as a Benjaminian document of civilization and of barbarism at once. It is a crude banalization of the postmodern position to suggest that it entirely reneges on modernity. Zygmunt Bauman's work is an excellent case in point here. Given the pessimism regarding Enlightenment and subsequent European history, it would be an easy step to consider the twentieth century's greatest disaster, the Nazi atrocities, as a consequence of modernity. But Bauman takes a much more circumspect postmodern attitude to the Holocaust. Citing sociological research into the victims of hijackings and terrorist activity, he indicates that so-called 'personality change' after the traumatic event is in fact illusory. What happens is that historical circumstances after the trauma favour the appearance of traits which were always latent, but which were not appropriate under the historical norms which conditioned the life of the victim before the traumatic event. A different aspect of the personality assumes the normative position: the same person remains. Bauman allegorizes this to consider the Holocaust:

> The unspoken terror permeating our collective memory of the Holocaust…is the gnawing suspicion that the Holocaust could be more than an aberration, more than a deviation from an otherwise straight path of progress, more than a cancerous growth on the otherwise healthy body of the civilized society; that, in short, the Holocaust was not the antithesis of modern civilization and everything (or so we like to think) it stands for. We suspect (even if we refuse to admit it) that the Holocaust could merely have uncovered another face of the same modern society whose other, so familiar, face we so admire. And that the two faces are perfectly comfortably attached to the same body.[32]

Modernity does not lead inexorably to the Holocaust; rather, the civilized face of modernity is attended constantly by a barbarism which is its Janus-complement.

The horror at the evil of the Holocaust is, for Bauman, really a horror at the rationality inscribed within the practice of the Holocaust. Enlightenment reason had enabled the development of an extraordinarily complete rationally ordered and self-sustaining social process. Part of the legacy of this is the development of efficiency in productivity, and the (often self-serving) development of technology. The horrifying truth of the matter, according to Bauman, is that 'every "ingredient" of the Holocaust…was normal, "normal" not in the sense of the familiar…but in the sense of being fully in keeping with everything we know about our civilization, its guiding spirit, its priorities, its immanent vision of the world'.[33] Structurally, the gas chambers are driven by the same presiding principles that were taken for granted as the positive aspects of modernity: rationalized efficiency in industrial production. The barbarism of the Holocaust arises because Enlightenment contained within its drive to reason a carcinogenic drive to rationalism, which can be used as well for fascist as for emancipatory ends. For a postmodern sociologist such as Bauman, it becomes difficult to disintricate the 'rationality of evil' from the 'evil of [modern, instrumental] rationality'. As he indicates, in the world of the

death camps, everything was rationalized: 'Each step on the road to death was carefully shaped so as to be calculable in terms of gains and losses, rewards and punishments.'[34] The SS also knew that, in a perversion of Enlightenment, but a perversion made possible precisely *by* Enlightenment, reason was their single best ally in ensuring that their victims would become complicit in their own suffering, betraying their fellows in the reasonable hope of prolonging their own lives thereby: 'to found their order on fear alone, the SS would have needed more troops, arms and money. Rationality was more effective, easier to obtain, and cheaper. And thus to destroy them, the SS men carefully cultivated the rationality of their victims.'[35]

Reason, which was supposed to legitimize the neo-pagan and emancipatory activities of Enlightenment, is now itself in need of legitimation. It can no longer assume the capacity for self-legitimation without assuming an exclusivity which necessarily victimizes other possible (and equally, if differently) reasonable narratives. Its claims upon universality are supplied by its inherent tendency to fall into the merest rationalism. It produces an administered society, and not a reasonable one; reason is replaced by efficiency and by the aesthetic and formal vacuities of rationalism. As both Derrida and Foucault have argued, though in very different ways, Enlightenment reason is profoundly exclusivist: it can legitimate itself only by first identifying and then stigmatizing its Other. As a result, Enlightenment reason is a potent weapon in the production of social normativity, driving people towards a conformity with a dominant and centred single 'norm' of behaviour. Reason, in short, has to produce the 'scandal' of its Other to keep itself going. Baudrillard has argued that this has an extremely important corollary effect in the twentieth century. In our time, it is not so much reason itself which requires legitimation as the very principle of reality (which, it is assumed, is founded upon rational principles). Society, in a move structurally parallel to Enlightenment reason, thus produces the Other of the real—fantasy—to legitimize the normativity of its own practices. Thus: 'Disneyland is there to conceal the fact that it is the "real" country, all of "real" America, which is Disneyland (just as prisons are there to conceal the fact that it is the social, in its entirety, in its banal omnipresence, which is carceral.'[36] The emancipation proposed by Enlightenment brings with it an incarcerating impetus: its 'freedom' turns out to be but the *form* of a freedom, an aesthetics rather than a politics of freedom. The name for this aestheticization of the political is *representation*. In the postmodern, representation, as both a political and an aesthetic category, has come under increasing pressure; and it is to this that we can now turn.

JUSTICE AND REPRESENTATION

Enlightenment reason is self-legitimizing: it takes one historically and culturally specific inflection of reason for the universal form of all Reason; and then adjudges all competing forms of reason to be, *ipso facto,* unreasonable.[37] In crude terms, Enlightenment Europe judged the rest of the cultures of the world in precisely the terms of Enlightenment Europe; and when, not surprisingly, it found the rest of the world to be 'different', it judged it to be inferior, unreasonable, 'underdeveloped'. Hence there arises the legitimation for a racist and imperialist consciousness which underpins some of the most

unjust actions of the modern world, culminating perhaps in the Holocaust. Enlightenment's difficulty, it seems, was in accepting the possibility of a plurality of the forms of reason, each specific to particular historical or cultural events in their singularity. That difficulty had its root in the tendency to abstraction, or to theory.

Equally abstract is the idea of a Universal History which, if it is to exist, must disregard the singularities of specific events, reading them as 'signs' or semiotic counters which can be meaningfully inserted into a governing and totalized master narrative. Given that a human culture or society is made possible precisely by the narratives which it tells to itself, then it becomes clear that what is at stake here is a massive political injustice.

The postmodern attack on the notion of a Universal History has important ramifications for the questions of representation and justice. As I indicated earlier, a Universal History is tacitly predicated upon a monotheism which brings in its wake an incipient totalitarianism. It presupposes a single transcendental position ('God') from which the whole of history can be recounted or truthfully narrated. Accordingly, if we subscribe to such notions, then all contradictory ('pagan') human narratives are automatically discarded and deemed to be nothing more than 'fictions'. In pragmatic fact, of course, this has meant that, as Benjamin and others have indicated, all history is told from the point of view of the victor, who, as a 'master narrator', assumes the position of a totalitarian author, or God; and any opposing narratives—such as the narratives which constituted the entire cultural and social history of the victim—are either ignored, denied or brought into line with the dominant narrative of the victor, from whose point of view they appear to be deviant, disjunctive and clearly false. The master narrator simply subsumes other competing narratives within a totalized framework, and assigns the competing narratives to a marginalized position. Those margins have, in modernism, been occupied by various figures such as dissidents, intellectuals, communists, women, lesbian and gay people, 'foreigners', and so on. In contrast to this, the postmodern faces the problematic possibility of a potentially endless and self-contradictory series of re-presentations *without the predication of an implied presence anywhere which would exist to ground or hierarchize the competing representations or narratives*.

In addition to this, and linked to it, is the political complication of the issue of justice. How can we judge an event? In the 'modern' world it is possible to judge according to specific criteria. These criteria are assumed to be shared by a social consensus. But this also implies an instance of presence somewhere, a fundamental ground of truth upon which all judgments can be made. That is to say, both representation and justice require a foundational theory. It is precisely such a theory that postmodernism would challenge, on the grounds that it is a theory which is always tacitly founded upon injustice and upon the covert violence of totalization.

Habermas would agree that no necessary foundation for a social formation exists prior to human beings in community. But he has consistently argued for the necessity of struggling towards the fabrication of a society founded upon a rational consensus. Lyotard challenges this on the grounds that consensus without the prior exercise of power and without covert injustice seems to be impossible; and on the grounds that such a consensus, which would of necessity conceal and act as a cover for the violences and injustices upon which the social is founded, may therefore not even be desirable.

For Lyotard, there is, in any achieved consensus, necessarily repression or, worse, oppression.[38] In order to circumvent this, he advocates that we multiply differences and that we bear witness to the differend, a term taken from legal discourse. A differend arises under specific circumstances: two opposed parties in a dispute are each in the right according to their own terms of reference; the terms of reference of each party cannot accommodate, or refuse to accommodate, the other party; and there is no common ground or third set of terms of reference which will allow an adjudication between the two parties while respecting their own terms of reference. In short, a differend arises when we lack a theory which will encompass radically divergent ('pagan') narratives. This may arise in a court of law; but, for Lyotard, it arises everywhere as an issue of justice and representation.[39]

Neither party to a differend can find an adequate representation of itself in the language-game of the other party. Each therefore feels violated by its insertion into that language-game. Further, we lack a 'neutral' or monotheistic theory which can encompass and adequately represent both parties. In the absence of criteria upon which to make the necessary judgments, how then do we judge?[40]

Judgment and representation are intimately related in the postmodern. The just has always been closely linked to the true; and justice depends upon a revelation of truth. There is a clear structural similarity between this and a Marxist hermeneutic. The project of an ideological demystification starts from the presupposition that a text (or the object of any critical judgment) is always informed by a specific historical and political nexus, and that the text is the site for the covering over (or disappearance) of the contradictions implicit in this historical conjuncture. The task of critical judgment here is in the first instance epistemological: it involves the necessary revelation of a truth lying concealed behind an appearance. But it is precisely the opposition between ideological appearance on one hand and foundational or true reality on the other which the postmodern puts under speculative pressure.

As Baudrillard has argued, the real in our time is no longer what it used to be. Technology has made it possible to confound the separation between the authentic and the fake, between the real and its representation, in ways far more radical than even Benjamin imagined. Yet that separation, of course, is precisely the separation required for a foundational philosophy or for any philosophy which has a strong investment in a univocal and transcendental notion of truth. The postmodern eschews any such simple access to the true or to foundational criteria upon which to base its acts of criticism or of judgment.

We live increasingly in the time of what Debord aptly called 'the society of the spectacle'. Our politics, and our justice, have become increasingly 'spectacular', a matter of 'show trials' and 'live' television courtroom drama. A poignant icon of this state of affairs is to be found in the example, often cited by Paul Virilio, of the women of the Plaza de Maya in Buenos Aires, who congregate in silence at regular intervals simply to bear witness to their relatives who have been made to 'disappear' by a cruel politico-military regime.[41] Political systems—including *soi-disant* 'democratic' systems—increasingly deal with dissident thought by controlling and regulating its appearances; and, on occasion, dissident thinkers themselves are entirely 'disappeared' either directly by force or indirectly by bureaucratic measures. The essence of the political in our time is

formulated not upon the old—the 'modernist'—relation between appearance and reality, but rather upon the relation between appearance and disappearance. Increasingly, the real itself is subject to this relation as well, when, for a random instance, the reality of the Gulf War of 1990 was reduced to the status of a video game, death and destruction disappearing until such times as the military decided it was appropriate for their reappearance before the population to be acceptable.[42]

Fundamentally, this shift has affected the status of knowledge upon which judgment and representation are based. The opposition of appearance to reality assumes necessarily that the Object of knowledge is stable, and that there exists a model for the Subject of knowledge which is transcendent. But in the postmodern mood, this has been contaminated by a historicity and mutability which render both Subject and Object unstable. As a result, knowledge itself—predicated upon a stable relation between the Subject and Object of knowledge, upon a moment of anagnorisis or recognition producing the Identity of the Subject—has entered into crisis.

This crisis was foreseen by Kant. In the *Critique of Pure Reason* Kant faced up to the question of the scientificity—by which he meant verifiability—of knowledge about the world; and he argued there for the necessity of a priori judgment in such matters. But more than this, he argued that an a priori knowledge gleaned simply from an analytic methodology would simply tell us a great deal about the methodology, and not necessarily anything new about the world: it would provide only *anamnesis*. That is to say, to perceive the world at all, consciousness needs a form in which to comprehend it; that form—the analytic method of perception—serves primarily the function of self-legitimation. Kant, like the contemporary postmodernist, wanted the world to be able to shock us into new knowledge, into the unforeseen and unpredictable. For Badiou, who makes a clear—and we might now say 'Kantian'—distinction between truth and the accumulation of knowledges, for instance, 'what is clear is that the *origin* of a truth is of the order of an event'.[43] Kant wanted the world to be able to shock us out of the ideological conditioning of our consciousness's structures. He wanted, thus, what he called the *synthetic a priori,* which would exceed the *analytic a priori*. The synthetic would not only confirm the method of epistemological analysis of the world; it would also allow for the structural modification of the very analytic method itself to account for and encompass a new given, the new and therefore unpredictable data of the world. It would thus provide not just anamnesis but what we would now call the event of knowledge, or knowledge as event rather than fact.

In the *Critique of Judgment,* this distinction between analytic and synthetic more or less maps directly on to a distinction between determining and reflective judgments, a distinction made much of by Lyotard in the question of postmodern justice. In a determining judgment, an analytic method determines—predetermines—the result of the judgment: as in mathematics, say, where the structure of arithmetic determines the result of its internally generated problems, such as those of addition or subtraction. In reflective judgment, we have a different state of affairs, for here, as in our judgments about the aesthetically beautiful, there are no predetermining rules in accordance with which we can verify our judgments: we judge 'without criteria', in the phrase made famous by Lyotard. In short, this means that we judge without a predetermining theory. Judgments, we could say, are replaced by acts or by events of judging: the aesthetic *form* of justice is

replaced by the political *event* of justice.

In this state of affairs, the operation of reason extends itself beyond its own internally coherent framework and attempts to grasp—or to make—the new. This extension is one in which we can see a shift in emphasis away from scientific knowledge towards what should properly be called narrative knowledge. Rather than knowing the stable essence of a thing, we begin to tell the story of the event of judging it, and to enact the narrative of how it changes consciousness and thus produces a new knowledge. The postmodern prefers the event of knowing to the fact of knowledge, so to speak.

But the central problem remains: how can one legitimize an 'event' of judging? With respect to what can one validate what must effectively be a singular act? For Lyotard, a credulity towards metanarratives (i.e., subscription to a prevailing theory against whose norms single events of judging might themselves be judged and validated) is tantamount to a concession to systems theory. Even Habermas, who is opposed to Lyotard on many counts, opposes this, seeing that in such systems theory 'belief in legitimacy…shrinks to a belief in legality'.[44] For Habermas, communicative action can lead to the establishment of consensus, which would provide the necessary—if always provisional—grounds upon which to make our judgments. But Lyotard would see the establishment of consensus as a means of arresting the flow of events, in such a way that truth would be reduced to an accumulation of knowledges. That is to say, in short, that consensus is the means whereby a philosophy of Becoming is reduced to a philosophy of Being. The modernist assumes that it is possible to pass from Becoming to Being; the postmodernist believes that any such move is always necessarily premature and unwarranted, and that its primary victim is truth in the guise of the event.

Politics, as we usually think it, depends upon consensus; most often, such consensus articulates itself under the rubric of 'representation', in which there is first an assumed consensus between representative and represented, and second the possibility of consensus among representatives. This is bourgeois democracy, and, for the postmodernist, hardly a democracy at all. In place of such a politics, the postmodernist makes the demand for a justice. Justice cannot happen under bourgeois democracy, which is always grounded in the tyranny of the many (and even, of course, in many 'democratic' systems, on the tyranny of the few—on the hegemonic control of thought and of mediatic representations, appearances and disappearances, exercised by a few who mediate the norms of a social formation). We may no longer be able to legislate comfortably between opposing or competing political systems, for we can no more subscribe to such totalizing forms; but we can address the instance, the event, of judging and of justice in its singularities.

Here lies the basis of the ethical demand in the postmodern, a demand whose roots lie in the work of a philosopher such as Levinas. We must judge: there is no escape from the necessity of judging in each particular case. Yet we have no grounds upon which to base our judgment. This is profoundly akin to Levinas:

> I have spoken a lot about the face of the Other as being the original site of the sensible…. The proximity of the Other is the face's meaning, and it means in a way that goes beyond those plastic forms which forever try to cover the face like a mask of their presence to perception. But always the face shows through

> these forms. Prior to any particular expression and beneath all particular expressions, which cover over and protect with an immediately adopted face or countenance, there is the nakedness and destitution of the expression as such, that is to say extreme exposure, defencelessness,vulnerability itself…. In its expression, in its mortality, the face before me summons me, calls for me, begs for me, as if the invisible death that must be faced by the Other, pure otherness, separated, in some way, from any whole, were my business.[45]

The 'face-to-face' implicates us in a response, in the necessity of sociality. We must behave justly towards the fact of the Other; but we cannot do that according to a predetermined system of justice or a predetermining political or ethical theory. The Other is itself always other than itself; it is not simply a displaced Identity in which we may once more recognize and reconstitute our self. The demand is for a just relating to alterity, and for a cognition of the event of heterogeneity. In short, therefore, we must discover—produce—justice. Here, for Lyotard and many others is the real political burden of the postmodern: the search for a just politics which will respect the differend that constitutes the event.

THE NEW PESSIMISM

Postmodernism has thrown the very fundamental notion of critique into doubt. It asks two basic questions of critique: first, given that, in order to be consistent internally, critique must have a theoretical foundation, how does it escape the injustice of violence; second, is critique not always accommodated by and within the existing totality of its ostensible object, and thereby rendered at best redundant and at worst complicit with its own defeat? Many conclude, as a consequence, that postmodernism is nihilist through and through, and that it gives succour to a contemporary socio-cultural and political state of affairs in which late capitalism carries on unabated and uncontested.

This view causes a particular concern among critics of culture, who, coincidentally with the rise of postmodernism in philosophy, have striven to validate mass and popular forms of culture, and who therefore see the work of critical philosophy to be thoroughly enmeshed in matters of general political interest. It is a widely held belief that the postmodern has somehow eradicated the boundaries supposed to exist between 'high art' and 'popular culture'. This is largely due to an understanding, deriving largely from Jameson, that the fundamental trope of postmodernism in art is pastiche, a 'parody without purpose'.[46] While modernists would cite or refer intertextually to a wide range of other artistic products (Joyce using Homer, say), they would do so for some specific ends. Postmodernists, it is argued, reiterate the same structural strategy of quotation, partial misrepresentation and so on, but they do this simply for the sake of it. In short, where modernism's strategy of quotation sent the Subject from one signified to another, postmodernism's similar strategy stays defiantly at the level of the signifier. We watch a rock video, in which allusions will be made to Hitchcock, say, and which may use archive cinematic footage; but the point is simply to play with such references and not to assign any governing 'meaning' or intentionality to them.

This is an 'ad hocism' which has seen its counterpart in some forms of contemporary architecture, where some architects have explicitly tried to accommodate their design to the various tastes and demands of a variegated community. Typically, contemporary popular art-forms plunder, and thereby question the 'value' of, the forms of high art, which are often deemed to be obstructively monumental. Modelling themselves on Duchamp, whose 'ready-mades' or 'LHOOQ' derive their power from the questioning of all modes of 'originality', contemporary artists frequently 'sample' or repeat the 'great works' of the past. In fact, as a result of this, much of the popular cultural product which goes under the name of the postmodern in our time is actually simply a continuation of the modern. It is frequently characterized by fragmentation instead of unity, by intertextuality or autoreferentiality instead of reference, by the prioritization of the signifier over the signified, and similar tropes and figures as we found in Joyce, Proust, Mann, Gide, Picasso, Kandinsky, Schoenberg, Stravinsky and others.

There is an important distinction, however. If the allusions and cultural cross-references made in contemporary popular art are not grasped by an audience, then so be it. There is nothing to be gained by such knowledge, which would only allow for the self-satisfying congratulation of narcissistic self-recognition and self-legitimation as a 'connoisseur'. The fundamental argument here is based upon a rather cheerful 'degradation' of knowledge, or at least a degradation of knowledge-as-fact in favour of knowledge-as-event.

Knowledge here has become nothing more than the next 'byte' on the computer screen, the next 30,000 pixel-image, the next software package. It is important to indicate that this is as much an effect of the technology of postmodernity as it is of any philosophical determinants of the cultural practices of postmodernism. For the philosopher or intellectual who assumes that his or her position is to be that of the critic whose criticisms are based upon knowledge, enlightenment, the pursuit of truth or at least of the better arguments in the interests of the construction of a 'rational society', this surely provokes a dismal pessimism.

Yet it would be true to say that this kind of pessimism is, in a sense, rather banal. With this form of pessimism, there yet remains the hope of Enlightenment, of an enlightenment possessed by the critic and therefore available to others. What is at stake in postmodernism is a much more rigorous form of Pessimism, one which will act as a philosophical counter to the Optimism on which Enlightenment and modernity are fundamentally grounded. As I indicated earlier, such Optimism projects into the future a moment of redemption of the present. It suggests the possibility and even the eventual necessity of a coincidence between intellection and material practice, between aesthetics and politics, between 'I' as the Subject of consciousness and 'me' as its Object. Thereby it suggests the immanence as well as the imminence of a moment of self-presence; and fundamentally, therefore, such an Optimism can be seen to be predicated upon a philosophy of Identity. If the postmodern is distinguishable from the modern, the distinction lies in the willingness of postmodernism to countenance and indeed to encourage a philosophy of alterity. The Pessimism of the postmodern lies in a realization that the future will not redeem the present; that the material world may be thoroughly resistant to consciousness and to our determination to master it by signification; that history, in short, does not exist *for* the Subject.

Such a Pessimism, of course, has nothing to do with an emotion of sadness. It is, rather, of the philosophical order of an ethical demand. If the crude formulation of Optimism is that 'all is for the best in the best of all possible worlds', then Pessimism does not strictly speaking simply or simplistically state the reverse, that 'all is for the worst in the worst of all possible worlds'. Rather, it takes as its first step the acknowledgement, even within modernist Optimism, that there are a number of 'possible worlds'. It advances from this that these possible worlds may exist simultaneously (in the form, say, of 'first' world, 'Third' world, 'underdeveloped' world, and so on), and that we should bear witness to the differend which constitutes their mutual relations. We cannot therefore homogenize these worlds, nor can we hierarchize their order of priority or normativity. We are in no position to speak of the 'all', and therefore cannot describe it as being either 'for the best' or 'for the worst': the 'all' is, in fact, precisely the kind of homogenizing semantic trope which postmodernism would counter with 'the local' or, better, the 'singularity of the event'. The singularity of the event always implicates the Subject in an act of judgment, and such judgments, made without criteria, are best faced both stoically and ethically.[47] Postmodern Pessimism derives from the realization that 'the just' can never be formulated; the positive aspect of such Pessimism lies in the realization that the just must be enacted, invented. History may not exist for the Subject; but the Subject must 'just' exist.

NOTES

1 For a full indication of the scope of these debates, see T.Docherty (ed.), *Postmodernism: A Reader* (Hemel Hampstead: Harvester-Wheatsheaf, 1993), and C.Jencks (ed.), *The Postmodern Reader* (London: Academy Editions, 1992).

SELECT BIBLIOGRAPHY

What follows here is a list of titles by Lyotard and by Baudrillard which are relevant to the theme, concept, practices or philosophies of postmodernism. Given the fact that postmodernism is explicitly eclectic, it does not comprise a representative selection of the writings available on postmodernism. For a more detailed bibliography of postmodernism, as opposed to a list of the writings of Lyotard and Baudrillard, the reader should consult the following texts: S. Connor, *Postmodernist Culture* (Oxford: Basil Blackwell, 1989); T.Docherty, *Postmodernism: A Reader* (London: Harvester-Wheatsheaf; New York: Columbia University Press, 1993); L.Hutcheon, *A Poetics of Postmodernism* (London: Routledge, 1988).

Baudrillard

Primary texts

4.1 *Le Système des objets,* Paris: Gallimard, 1968.
4.2 *La Société de consommation,* Paris: Gallimard, 1970.
4.3 *Pour une critique de l'économie politique du signe,* Paris: Gallimard, 1972.

4.4 *Le Miroir de la production,* Tournail: Casterman, 1973.
4.5 *L'Echange symbolique et la mort,* Paris: Gallimard, 1976.
4.6 *L'Effet Beaubourg,* Paris: Galilée, 1977.
4.7 *Oublier Foucault,* Paris: Galilée, 1977.
4.8 *De la séduction,* Paris: Denoël, 1979.
4.9 *Simulacres et simulation,* Paris: Galilée, 1981.
4.10 *Les Stratégies fatales,* Paris: Grasset, 1983.
4.11 *La Gauche divine,* Paris: Grasset, 1985.
4.12 *Amérique,* Paris: Grasset, 1986.
4.13 *L'Autre par lui-même,* Paris: Galilée, 1987.
4.14 *Cool Memories,* Paris: Galilée, 1987.
4.15 *La Guerre du golfe n'a pas eu lieu,* Paris: Galilée, 1991.

Translations

4.16 *The Mirror of Production,* trans. M.Poster, St Louis: Telos Press, 1975.
4.17 *For a Critique of the Political Economy of the Sign,* trans. C.Levin, St Louis: Telos Press, 1981.
4.18 *In the Shadow of the Silent Majorities,* trans. P.Foss, P.Patton, and J. Johnston, New York: Semiotext(e), 1983.
4.19 *Simulations,* trans. P.Foss, P.Patton, and P.Beitchman, New York: Semiotext(e), 1983.
4.20 *The Evil Demon of Images,* Sydney: Power Institute Publications, 1987.
4.21 *Selected Writings,* ed. M.Poster, Cambridge: Polity Press, 1988.

Lyotard

Primary texts

4.22 *La Phénoménologie,* Paris: PUF, 1954.
4.23 *Dérives à partir de Marx et Freud,* Paris: Union Générale d'Editions, 10/18, 1970.
4.24 *Discours, figure,* Paris: Klincksieck, 1971.
4.25 *L'Economie libidinale,* Paris: Minuit, 1974.
4.26 *Instructions païennes,* Paris: Galilée, 1977.
4.27 *Rudiments païens,* Paris: Union Générale d'Editions, 1977.
4.28 *La Condition postmoderne,* Paris: Minuit, 1979.
4.29 *Le Mur du pacifique,* Paris: Galilée, 1979.
14.30 *Le Différend,* Paris: Minuit, 1983
14.31 *L'Assassinat de l'expérience par la peinture: Monory,* Paris: Le Castor Astral, 1984.
14.32 *Le Tombeau de l'intellectuel,* Paris: Galilée, 1984.
14.33 *L'Enthousiasme: la critique kantienne de l'histoire,* Paris: Galilée, 1986.
14.34 *Le Postmoderne expliqué aux enfants,* Paris: Galilée, 1986.
14.35 'Sensus Communis', *Le Cahier du Collége International de Philosophie,* 3 (1987):67–87.

14.36 *L'Inhumain,* Paris: Galilée, 1988.
14.37 *Leçons sur l'analytique du sublime,* Paris: Galilée, 1991.
14.38 Lyotard, J.-F. and Chaput, T., *Less Immatériaux,* Paris: Centre Georges Pompidou, 1985.
14.39 Lyotard, J.-F. and Francken, R., *L'Histoire de Ruth,* Paris: Le Castor Astral, 1983.
14.40 Lyotard, J.-F. and Monory, J., *Récits tremblants,* Paris: Galilée, 1977.
14.41 Lyotard, J.-F. and Thébaud, J.-L., *Au juste,* Paris: Christian Bourgois, 1979.
14.42 Lyotard, J.-F. et al., *La Faculté de juger,* Paris: Minuit, 1983.

Translations

14.43 'One of the Things at Stake in Women's Struggles', *SubStance,* 20 (1978): 9–17.
14.44 *The Postmodern Condition: A Report on Knowledge,* trans. G.Bennington and B.Massumi, Manchester: Manchester University Press, 1984.
14.45 *The Differend,* trans. G.van den Abbeele, Manchester: Manchester University Press, 1990.
14.46 *Peregrinations,* New York: Columbia University Press, 1988.
14.47 *The Lyotard Reader,* ed. A.Benjamin, Oxford: Blackwell, 1989.
14.48 *Just Gaming,* trans. W.Godzich, Manchester: Manchester University Press, 1985.
14.49 Lyotard, J.-F. and Rorty, R, 'Discussion', *Critique,* 41 (1985):581–4.

Glossary

alterity—a perspective on otherness that goes beyond mere binary opposition. In the work of Emmanuel Levinas, the other is ethically prior to any projection of self.

apodictic—a term used to refer to that which is absolutely certain and necessarily true. Husserl introduced the phenomenological method in order to make philosophy a 'rigorous' science based on apodictic grounds.

aporia—from the Greek *apeiron* (boundless, infinite). Term used for a puzzling question or theme that generates other questions, but has no clear and simple resolution.

apperception—a primary tenet of the philosophy of reflective consciousness that refers to an awareness of one's own changing mental states. For Kant transcendental apperception describes the unity of consciousness (pure ego) that precedes and synthesizes our perceptions, thus grounding any possibility of experience at all.

binary opposition—a principle first explored in the theory of Ferdinand de Saussure, the Swiss linguist whose *Cours de linguistique générale* (1916) pointed out the relational features of language that later influenced the development of structuralism. It identifies the 'phonemic' differences that allow us to recognize significant contrasts between words as spoken (e.g., bat/cat), while at the same time ignoring phonemic differences that are not used to distribute meaning in a particular language (e.g., coat/caught).

categorical imperative—Kant's 'moral law' which is universally binding by self-legislating reason. One formulation would be: 'Act only on that maxim through which you can at the same time will that it should become a universal law.'

critical theory—in its most general application, designates the activity of cultural critique as philosophical *praxis*. This would include *Kulturkritik* as practised by members of the Frankfurt school (Horkheimer, Marcuse, Adorno, Benjamin and Habermas), as well as by French and Italian social philosophy represented by Gramsci, Foucault, Althusser and Lyotard. A broad category encompassing studies using Marxist and Freudian methods of analysis, as well as works focusing on aesthetics and mass culture.

Dasein—Heidegger's term to designate 'that being for whom Being is an issue', a concept most fully developed in *Being and Time*. Originally a word in German simply meaning 'existence', it takes on a contextualized resonance, and Heidegger stressed that *Dasein* was never to be understood simply as the Cartesian 'subject'.

deconstruction—a term used by Jacques Derrida to describe the strategies and tactics which can be used to re-examine the presuppositions of texts which are usually read from a logocentric perspective. It represents a philosophical challenge to the 'metaphysics of presence' by including attention to the negative term which is always left as a trace of supplementary meanings.

différance—more than just the difference *(différence)* that stands in opposition to identity, this term is used by Derrida to describe the prior ground upon which such oppositions are constructed. As such, it always resists binary categories by going

beyond them.

differend ***(différend)***—a term used by Jean-François Lyotard to emphasize the incommensurability of different 'language games' that usually results in the silencing of the weaker participant. A persistent heterogeneity that can never be reduced to sameness.

discourse ethics—a term used by Jürgen Habermas to refer to the linguistic dimension of his project for communicative action. All speakers have the right to freely argue for normative claims that possess universal validity.

eidos—Greek term which has been used in various ways to convey the sense of form, shape, appearance, image or idea. Plato uses this term for his abstract Forms or Ideas reflecting universal essences. For Husserl *eidos* is the essence of a noematic content revealed by the phenomenological method of inquiry. (See also *phenomenology*.)

epochē—the bracketing or suspension of empirical and metaphysical presuppositions of the 'natural attitude'. Husserl proposed such bracketing as the first methodological move of his phenomenology.

être-en-soi—Sartre's term for 'being-in-itself', a mere thing which is acted upon and remains passive. For Sartre this entails inauthentic existence, which evades the responsibility for making choices. Opposed to être-pour-soi, being-for-itself, which actively makes choices and takes responsibility in living authentically.

existentialism—in the twentieth century, the philosophy of existence developed ideas of both Kierkegaard (1813–55) and Nietzsche (1844–1900) that stressed the primacy of individual freedom, choice and responsibility in a world devoid of absolute values. Significant contributors would be Jean-Paul Sartre, Albert Camus and Simone de Beauvoir.

Frankfurt school—founded in 1923, the major centre for critical theory during the 1930s, and re-established after the Second World War, when many of its members were forced to flee to America. (See also *critical theory*.)

fusion of horizons—a concept used by Hans-Georg Gadamer *(Horizontverschmelzung)* to indicate the importance of recognizing historical distance in the activity of philosophical hermeneutics. Approaching any text necessarily brings together the historical horizon of the interpreter, which must be taken into account, with that of an historically distant tradition.

genealogy—a term used first by Nietzsche and later by Foucault to describe the historical interrogation of discursive practices that produce knowledge and shape institutions. Neither predictably evolving nor continuous, these discourses reveal the ultimate locus of power relations that construct the subject.

grammatology—the science of the written sign proposed by Derrida that challenged the dominance of spoken (phonocentric) discourse which privileges presence. The written sign is thus left open to alternative interpretations and meanings.

hegemony—a concept developed by Antonio Gramsci that stresses the ideological importance of cultural institutions in protecting the interests of a dominant class. Apparent consensus is achieved by a political and cultural leadership that transmits and legitimates its own values, which remain unexamined as ideologically neutral. The concept changed the focus of much Marxist theory from the economic base to superstructure.

hermeneutics—a term broadly defined by Paul Ricoeur as 'the art of deciphering indirect meaning'. This philosophical task of interpretation proceeds via the mediations of symbol, myth, dream, image, narrative, text and ideology. For Gadamer as well, all encounters with tradition must be viewed through this structure of interpretation.

hermeneutics of suspicion—the practice of critical or 'depth' hermeneutics that reveals the hidden and often ideological nature of texts, events and social practices. Ricoeur identifies three 'masters of suspicion': Marx, Nietzsche and Freud.

ideal speech situation—a concept suggested by Habermas to describe the required conditions of equality and free, unencumbered speech for participants to reach a universally binding consensus in rational discourse.

ideology—For Marx this meant 'false consciousness', that is, the complex of abstract beliefs that ignore historical and material existence by distorting and concealing social contradictions. The Marxist critiques of religion and German idealism aim to highlight this contradiction. Expanded by the work of Gramsci who recognized the importance of the 'superstructure' in supporting ideological hegemony through cultural institutions. Less negatively, for Ricoeur, the natural inclination within any social grouping to bind itself through foundational myths that appeal to tradition and resist change.

instrumental rationality—a translation of Max Weber's concept *Zweckrationalität,* which identifies goal-oriented rationality as 'the iron cage' from which we cannot escape. It permeates our lives in the form of increasing bureaucracy and narrowing expertise. It greatly influenced Horkheimer's and Adorno's critique of Enlightenment rationality, *Dialectic of Enlightenment*.

intentionality—a concept revived by Franz Brentano from medieval philosophy and later more fully developed by Edmund Husserl in his phenomenology. His emphasis on consciousness as always 'consciousness-of-something' is the foundation for his noetic-noematic structure of the intentional act. Consideration must be given to both the noetic act itself (willing, believing, etc.), as well as to the noematic 'content' of this act. Only in this way is the essence or *eidos* of what is intended revealed. For Husserl, the three modes of intentionality (perception, imagination, and signification) are fully interrelated.

jouissance—While this term is usually translated from the French as 'pleasure', it connotes an orgasmic joy and release that engages the whole body.

life-world *(Lebenswelt)*—a term used in the late work of Husserl (*The Crisis of the European Sciences,* 1937), referring to a shared background of culture, tra-dition and language that contextualizes subjective experience. The prototype of the life-world can be found in the life-philosophy and hermeneutic work of Wilhelm Dilthey who developed Hegel's concept of life and its domain of internal relations. Dilthey also greatly influenced Heidegger's focus on lived, historical experience in *Being and Time* (1927). Most recently, the term reemerges in Habermas's theory of communicative action.

logocentrism—philosophical thinking that privileges 'presence' and attempts to define reality, truth, and knowledge with a concept of 'being' which is rooted in identifiable binary oppositions.

mauvaise-foi—a term used by Sartre that literally means 'bad faith', a mode of living

inauthentically and passively. A refusal to acknowledge that one always has the freedom to choose.

Naturwissenschaft—the German for 'natural philosophy', the study of nature in general. Originally used to refer specifically to the science of investigating mechanistic principles and laws within the field of physics. Opposed to *Geisteswissenschaften* (human sciences) in the work of early hermeneutic theorists such as Dilthey.

noema—see *phenomenology*.

norms—a term referring to the standards or rules invoked to guide human conduct in determining what *ought* to be done, or what one is obliged to do, in an ideal and regulative sense.

ontological difference—for Heidegger, the distinction between 'Being' *(Siein)* and 'beings' *(Seiende),* which emphasizes that merely cataloguing existing beings or 'entities' ignores the ontological priority of Being-qua-Being.

ontology—a branch of philosophy that investigates 'being-as-being'. Questions are raised regarding topics in the metaphysical domain, such as the nature of reality, existence, essence and necessity.

ousia—from the Greek for 'substance'. The term used by Aristotle to indicate the most important and permanent of his ten categories.

phallocentrism—a form of logocentric thinking in which the phallus takes on the identity of *logos* or reason. Women are thereby defined within the context of patriarchal relations which represents them exclusively from a male perspective.

phenomenology—one of the most influential philosophies of the twentieth century, developed by Edmund Husserl. He attempted to secure a rigorous method for describing the vital role of human consciousness in constituting meaning. His project to go 'back to the things themselves' ('zu den Sachen selbst'), first announced in *Logical Investigations* (1900), required a step back from 'the natural attitude' of common sense in an effort to describe the essential contents *(noema)* of our intending acts *(noesis),* Husserl's 'eidetic phenomenology' was later revised by Heidegger into a 'hermeneutic' and 'existential' phenomenology (*Being and Time,* 1927), which in turn influenced numerous philosophers, such as Gadamer, Ricoeur, Merleau-Ponty and Sartre. (See also *intentionality*.)

positivism—the view of scientific methodology that privileges 'neutral' observation and control in experimental procedures. First envisioned by Auguste Comte (1798–1857) as the most developed stage of human development, it is now associated with technological rationalization and control.

postmodernism—a term used by Jean-François Lyotard (*The Postmodern Condition,* 1979) to refer to the radical and constant mutability contained within the concept of modernism itself; not to be understood simply as a 'stage' that comes after or replaces modernism. An influential challenge to the notion of the autonomous subject guided by the metanarratives of historical consciousness, postmodernism has affected varied intellectual domains, such as philosophy, literature and an.

poststructuralism—shares with structuralism the rejection of the paradigm of the human subject as the self-contained *cogito* or consciousness found in phenomenology and existentialism. However, it also rejects the static internal relations of the structuralist model, opting instead for multiple possibilities within the signifier-signified

combinations. The later work of some French philosophers who began as 'structuralists' (e.g., Lacan, Barthes) most closely fits this stance. (See also *semiotics*.)

readiness-to-hand *(Zuhandenheit)*—for Heidegger, *Dasein's* relationship to entities as practical comportment and everyday involvement, e.g., just *using* the hammer and not consciously articulating the process. Contrasts with the concept of 'Presence-at-Hand' *(Vorhandenheit),* whereby *Dasein* regards an 'object' with abstract (circumspective) comportment.

reification—a concept *(Verdinglichung)* used by Marx to describe the reduction of human beings and human relations to 'thing-like' objects, as well as the alienation of human labour from the material objects produced by its own work. Later much developed by Lukács in the longest chapter of *History and Class Consciousness*.

semiotics—a 'science of signs', also known as semiology, developed by Ferdinand de Saussure in Europe and C.S.Peirce in America. Studies the constitutive-relational nature of signs and their communicative properties in society. The linguistic sign is a structural relationship between an acoustic 'signifier' and the concept or 'signified' it refers to. Much extended by Roland Barthes in his analyses of social semiotics where signification is heavily dependent on the connotation or associative powers of the sign, in popular culture and advertising especially.

signifier, signified—see *semiotics*.

social imaginary—for Ricoeur, the symbolic discourses which permit the formation of complex socio-political groupings. Foundational symbols and myths provide the ideological basis for this identity, which is constantly tested by the potential for change and the need for change (Utopian possibilities).

structuralism—a movement focusing on internal structural relations rather than content, based on the linguistic method of analysis developed by Ferdinand de Saussure. He suggested that language constituted a self-contained system, wherein meaning was generated within language itself rather than merely reflecting a 'given' reality. This revolutionary claim, and the methodology it entailed, attracted immense interest across a spectrum of intellectual disciplines. Lévi-Strauss applied de Saussure's insights to anthropology, Lacan to psychoanalysis, Althusser to Marxism and Foucault to his wide-ranging social critique. The exponents of structuralism maintained an adversarial relation with existentialists and phenomenologists, whose belief in a transcendentally free human subject was rejected. (See *also poststructuralism*.)

technē—from the Greek for skill, art, or craft. For Aristotle anything created by humans, as opposed to *physis* (nature) which is anything not humanly crafted. This knowledge of *how* to reach a desired end can be procedural as well, and would include not only the fine arts of music, dance, poetry, drama, etc., but also such special skills as rhetoric and medicine.

Mara Rainwater, University College Dublin

Routledge History of Philosophy
Volume IX

Philosophy of Science, Logic and Mathematics in the 20th Century

Also available as a printed book
see title verso for ISBN details

Routledge History of Philosophy
Volume IX

Volume IX of the *Routledge History of Philosophy* surveys ten key topics in the philosophy of science, logic and mathematics in the twentieth century. Each of the essays is written by one of the world's leading experts in that field. The papers provide a comprehensive introduction to the subject in question, and are written in a way that is accessible to philosophy undergraduates and to those outside of philosophy who are interested in these subjects. Each chapter contains an extensive bibliography of the major writings in the field.

Among the topics covered are the philosophy of logic, of mathematics and of Gottlob Frege; Ludwig Wittgenstein's *Tractatus;* a survey of logical positivism; the philosophy of physics and of science; probability theory, cybernetics and an essay on the mechanist/vitalist debates.

In addition to these papers, the volume contains a helpful chronology to the major scientific and philosophical events in the twentieth century. It also provides an extensive glossary of technical terms in the philosophy of science, logic and mathematics, and brief biographical notes on major figures in these fields.

Stuart G.Shanker is Professor of Philosophy and of Psychology at York University, Canada. He has published widely on the philosophy of Ludwig Wittgenstein and artificial intelligence.

Routledge History of Philosophy

General Editors—G.H.R.Parkinson and S.G.Shanker

The *Routledge History of Philosophy* provides a chronological survey of the history of western philosophy, from its beginnings in the sixth century BC to the present time. It discusses all major philosophical developments in depth. Most space is allocated to those individuals who, by common consent, are regarded as great philosophers. But lesser figures have not been neglected, and together the ten volumes of the *History* include basic and critical information about every significant philosopher of the past and present. These philosophers are clearly situated within the cultural and, in particular, the scientific context of their time.

The *History* is intended not only for the specialist, but also for the student and the general reader. Each chapter is by an acknowledged authority in the field. The chapters are written in an accessible style and a glossary of technical terms is provided in each volume.

I *From the Beginning to Plato*
C.C.W.Taylor

II *Hellenistic and Early Medieval Philosophy*
David Furley

III *Medieval Philosophy*
John Marenbon

IV *The Renaissance and C17 Rationalism*
G.H.R.Parkinson (published 1993)

V *British Philosophy and the Age of Enlightenment*
Stuart Brown

VI *The Age of German Idealism*
Robert Solomon and Kathleen Higgins (published 1993)

VII *The Nineteenth Century*
C.L.Ten (published 1994)

VIII *Continental Philosophy in the C_20*
Richard Kearney (published I993)

IX *Philosophy of Science, Logic and Mathematics in the C_20*
S.G.Shanker

X *Philosophy of Meaning, Knowledge and Value in the C_20*
John Canfield

Each volume contains 10–15 chapters by different contributors

General editors' preface

The history of philosophy, as its name implies, represents a union of two very different disciplines, each of which imposes severe constraints upon the other. As an exercise in the history of ideas, it demands that one acquire a 'period eye': a thorough understanding of how the thinkers whom it studies viewed the problems which they sought to resolve, the conceptual frameworks in which they addressed these issues, their assumptions and objectives, their blind spots and miscues. But as an exercise in philosophy, we are engaged in much more than simply a descriptive task. There is a crucial, critical aspect to our efforts: we are looking for the cogency as much as the development of an argument, for its bearing on questions which continue to preoccupy us as much as the impact which it may have had on the evolution of philosophical thought.

The history of philosophy thus requires a delicate balancing act from its practitioners. We read these writings with the full benefit of historical hindsight. We can see why the minor contributions remained minor and where the grand systems broke down: sometimes as a result of internal pressures, sometimes because of a failure to overcome an insuperable obstacle, sometimes because of a dramatic technological or sociological change, and, quite often, because of nothing more than a shift in intellectual fashion or interests. Yet, because of our continuing philosophical concern with many of the same problems, we cannot afford to look dispassionately at these works. We want to know what lessons are to be learned from the inconsequential or the glorious failures; many times we want to plead for a contemporary relevance in the overlooked theory or to consider whether the 'glorious failure' was indeed such or simply ahead of its time: perhaps even ahead of its author.

We find ourselves, therefore, much like the mythical 'radical translator' who has so fascinated modern philosophers, trying to understand an author's ideas in their and their culture's eyes, and, at the

same time, in our own. It can be a formidable task. Many times we fail in the historical undertaking because our philosophical interests are so strong, or lose sight of the latter because we are so enthralled by the former. But the nature of philosophy is such that we are compelled to master both techniques. For learning about the history of philosophy is not just a challenging and engaging pastime: it is an essential element in learning about the nature of philosophy—in grasping how philosophy is intimately connected with and yet distinct from both history and science.

The *Routledge History of Philosophy* provides a chronological survey of the history of western philosophy, from its beginnings up to the present time. Its aim is to discuss all major philosophical developments in depth, and, with this in mind, most space has been allocated to those individuals who, by common consent, are regarded as great philosophers. But lesser figures have not been neglected, and it is hoped that the reader will be able to find, in the ten volumes of the *History,* at least basic information about any significant philosopher of the past or present.

Philosophical thinking does not occur in isolation from other human activities, and this *History* tries to situate philosophers within the cultural, and in particular the scientific, context of their time. Some philosophers, indeed, would regard philosophy as merely ancillary to the natural sciences; but even if this view is rejected, it can hardly be denied that the sciences have had a great influence on what is now regarded as philosophy, and it is important that this influence should be set forth clearly. Not that these volumes are intended to provide a mere record of the factors that influenced philosophical thinking; philosophy is a discipline with its own standards of argument, and the presentation of the ways in which these arguments have developed is the main concern of this *History*.

In speaking of 'what is now regarded as philosophy', we may have given the impression that there now exists a single view of what philosophy is. This is certainly not the case; on the contrary, there exist serious differences of opinion, among those who call themselves philosophers, about the nature of their subject. These differences are reflected in the existence at the present time of two main schools of thought, usually described as 'analytic' and 'continental' philosophy respectively. It is not our intention, as general editors of this *History,* to take sides in this dispute. Our attitude is one of tolerance, and our hope is that these volumes will contribute to an understanding of how philosophers have reached the positions which they now occupy.

One final comment. Philosophy has long been a highly technical subject, with its own specialized vocabulary. This *History* is intended not only for the specialist but also for the general reader. To this end, we have

tried to ensure that each chapter is written in an accessible style; and since technicalities are unavoidable, a glossary of technical terms is provided in each volume. In this way these volumes will, we hope, contribute to a wider understanding of a subject which is of the highest importance to all thinking people.

G.H.R.Parkinson
S.G.Shanker

Notes on contributors

Joseph Agassi is Professor of Philosophy at Tel-Aviv University and York University, Toronto (joint appointment); M.Sc. in physics from Jerusalem; Ph.D. in general science: logic and scientific method from London (The London School of Economics). Among his major publications in English are: *Towards an Historiography of Science, History and Theory, The Continuing Revolution: A History of Physics From The Greeks to Einstein, Faraday as a Natural Philosopher, Towards a Rational Philosophical Anthropology, Science and Society: Studies in the Sociology of Science, Technology: Philosophical and Social Aspects, Introduction to Philosophy: The Siblinghood of Humanity* and *A Philosopher's Apprentice: In Karl Popper's Workshop*.

James Bogen is Professor of Philosophy at Pitzer College, Claremont, California. His publications on Wittgenstein include *Wittgenstein's Philosophy of Language,* 'Wittgenstein and Skepticism' and a critical notice of Bradley's *Nature of all Being*. Having published in several areas, including epistemology, philosophy of science and ancient Greek philosophy, he is now working on a project in the history of nineteenth-century neuroscience.

Rainer Born was born in 1943 in Central Europe. He was educated as a teacher and studied (in Austria, Germany and England) philosophy, mathematics, physics, psychology and pedagogics, leading to degrees in 'philosophy and mathematics', habilitation (venia docendi) for 'Theory and philosophy of science'. He is currently an Associate Professor at the Institute for Philosophy and Philosophy of Science at the Johannes Kepler University, Linz, Austria.

Jeff Coulter is Professor of Sociology and Associate Faculty Member of Philosophy at Boston University. Among his publications are *The Social*

Construction of Mind (1979), *Rethinking Cognitive Theory* (1983), *Mind In Action* (1989) and (with G.Button, J.Lee and W. Sharrock) *Computers, Minds, and Conduct* (1995).

Michael Detlefsen is Professor of Philosophy at the University of Notre Dame and editor-in-chief of the *Notre Dame Journal of Formal Logic*. He is author of *Hilbert's Program* and of various papers in the philosophy of mathematics and logic. Presently, he is working on two books: one on constructivism in the foundations of mathematics and the other on Gödel's Theorems.

Oswald Hanfling is Professor of Philosophy at The Open University. He is author of *Logical Positivism, Wittgenstein's Later Philosophy, The Quest for Meaning* and *Philosophy and Ordinary Language* (nearing completion). He is also editor and part author of *Philosophical Aesthetics: An Introduction* as well as various Open University texts.

Rom Harré is a Fellow of Linacre College, Oxford, and the University Lecturer in the Philosophy of Science. He is also Professor of Psychology at Georgetown University, Washington DC, and Adjunct Professor of Philosophy at Binghamton University. He is the author of such books as *Varieties of Realism, Social Being, Personal Being, Laws of Nature,* and with Grant Gillett *The Discursive Mind*. He is also the editor, with Roger Lamb, of the *Blackwell Encyclopedic Dictionary of Psychology*.

Andrew Irvine is an Associate Professor of Philosophy at the University of British Columbia. He is the editor of *Physicalism in Mathematics* (Kluwer, 1990) and co-editor of *Russell and Analytic Philosophy* (University of Toronto, 1993).

Kenneth M.Sayre received his Ph.D. from Harvard University in 1958, and has since been at the University of Notre Dame where currently he is Professor of Philosophy. He is the author of several books, monographs and articles on the topics of cybernetics and the philosophy of mind, including *Consciousness: A Philosophic Study of Minds and Machines, Cybernetics and the Philosophy of Mind* and *Intentionality and Information Processing: An Alternative Model for Cognitive Science*. He contributed the article on Information Theory in Routledge's new *Encyclopedia of Philosophy*.

Stuart Shanker is Professor of Philosophy and Psychology at Atkinson College, York University. He is author of *Wittgenstein and the Turning Point in the Philosophy of Mathematics* and editor of *Ludwig Wittgenstein: Critical Assessments* and *Gödel's Theorem in Focus*. He will shortly be

publishing *Wittgenstein and the Foundations of AI,* and with E.S.Savage-Rumbaugh and Talbot J.Taylor, *Apes, Language and the Human Mind: Essays in Philosophical Primatology*.

Acknowledgements

I am deeply indebted to my co-general editor, G.H.R.Parkinson, for all the help he has given me in preparing this volume, and Richard Stoneman, who has been an invaluable source of advice in the planning of this History. I would also like to thank Richard Dancy, who prepared the chronology for this volume, and Dale Lindskog and Darlene Rigo, who prepared the glossary. Finally, I would like to thank the Canada Council, which supported this project with a Standard Research Grant; Atkinson College, which supported this project with two research grants; and York University, which awarded me the Walter L.Gordon Fellowship.

Chronology

The following sources have been consulted for much of the material on science and technology: Alexander Hellemans (ed.) *The Timetables of Science* (New York, Simon and Schuster, 1987); Bruce Wetterau, *The New York Public Library Book of Chronologies* (New York, Prentice Hall, 1990).

	Philosophy (general)	Philosophy of science	Science and technology
1840		Whewell, *Philosophy of the Inductive Sciences*	
1865	Mill, *Examination of Sir William Hamilton's Philosophy*		
1866		Lange, *History of Materialism*	
1872		E. Dubois-Raymond, *The Limits of Natural Knowledge*	
1873		Jevons, *The Principles of Science*	Maxwell, *Electricity and Magnetism*
1874		Kirchoff, *Principles of Mechanics*	
1877	Peirce, 'The Fixation of Belief'		
1878	Peirce, 'How to Make Our Ideas Clear' Peirce, 'The Doctrine of Chances'		
1881		Helmholtz, *Popular Lectures*	Michelson–Morley experiment (speed of light found to be the same in perpendicular directions)
1883		Mach, *The Science of Mechanics*	
1885		Clifford, *Commonsense of the Exact Sciences*	
1892	Frege, 'On Sense and Reference'	Pearson, *The Grammar of Science*	Lorentz–Fitzgerald contraction (contraction of objects at high speeds)
1893	Bradley, *Appearance and Reality* Peirce, *Search for a Method* (not completed)	Mach, *Popular Scientific Lectures* Hertz, *The Principles of Mechanics*	
1894	Peirce, *The Principles of Philosophy* (not completed)		

1895			Discovery of x-rays (Röntgen), cloud chamber developed (Thomson)
1897			Discovery of electron (Thomson), charge of electron measured (Thomson)
1898		Peirce, *The History of the Sciences* (not completed)	Term 'radioactivity' coined (M. Curie) Alpha and beta rays (radioactivity from uranium) discovered (Rutherford)
1900	Husserl, *Logical Investigations*		Quantum theory initiated: substances can emit light only at certain energies (Planck)
1902		Poincaré, *Science and Hypothesis*	Rutherford and Soddy: 'The Cause and Nature of Radioactivity'
1903	Moore, 'Refutation of Idealism' Moore, *Principia Ethica* Peirce, 'Pragmatism' (Harvard lectures)		
1904		Duhem, *The Aim and Structure of Physical Theory*	Thomson's model of the atom: electrons embedded in sphere of positive electricity
1905	Russell, 'On Denoting' Mach, *Knowledge and Error*	Boltzmann, *Popular Writings*	Einstein explains Brownian motion (motion of small particles suspended in liquid); seen as first proof of existence of atoms Einstein's papers on the special theory of relativity Einstein postulates light quantum (term 'photon' coined 1926) for particle-like behaviour of light
1907	James, *Pragmatism* Bergson, *Creative Evolution*		
1908			Minkowski, *Space and Time* (proposes 4 dimensional universe)

	Philosophy (general)	Philosophy of science	Science and technology
1910			Marie Curie, *Treatise on Radioactivity*
1911			Rutherford's atomic theory: positively charged nucleus surrounded by negative electrons
1913	Husserl, *Ideas: General Introduction to Pure Phenomenology*		Bohr's model of the atom: electrons revolve around nucleus in fixed orbits, give off fixed quanta of energy by jumping orbit
1914	Russell, *Our Knowledge of the External World* Bradley, *Essays on Truth and Reality*	Broad, *Perception, Physics, and Reality*	Discovery of proton (Rutherford)
1915			Einstein's general theory of relativity
1917		Schlick, *Space and Time in Contemporary Physics*	Existence of black holes predicted (Schwarzschild)
1918	Russell, *The Philosophy of Logical Atomism* Schlick, *General Theory of Knowledge*		Third law of thermodynamics (Nernst)
1920	Whitehead, *The Concept of Nature*	Campbell, *Physics: The Elements*	Existence of neutron (uncharged particle) proposed (Harkins); discovered 1932 Red shift in spectra of galaxies reported (Slipher) Copenhagen Institute of Theoretical Physics founded (Bohr)
1921	Wittgenstein, *Tractatus Logico-Philosophicus*	Haldane, *The Reign of Relativity*	
1923		Broad, *Scientific Thought*	Particle-wave duality of matter proposed (de Broglie); confirmed 1927 (Davisson)
1924			Bose statistics for light quanta (Bose) Galaxies shown to be independent systems (Hubble)

1925		Whitehead, *Science and the Modern World*	Electron spin hypothesized (Goudsmit and Uhlenbeck) Pauli's exclusion principle (electrons of same quantum number cannot occupy same electron) Quantum mechanics given first comprehensive formulation (Born, Heisenberg and Jordan) 'Scopes Monkey Trial' (high-school teacher prosecuted for teaching evolution)
1926			Probability interpretation of quantum mechanics (Born) Fermi–Dirac statistics Planck's law derived from first principles (Dirac) First paper on wave mechanics (Schrödinger); Schrödinger's equation
1927	Heidegger, *Being and Time* McTaggart, *The Nature of Existence*	Russell, *The Analysis of Matter* Weyl, *Philosophy of Mathematics and Natural Science* Bridgman, *The Logic of Modern Physics*	Heisenberg's uncertainty principle (cannot determine simultaneously position and momentum of electron) First version of 'Big Bang' theory of origins of universe (Lemaitre)
1928	Carnap, *The Logical Structure of the World*	Eddington, *The Nature of the Physical World* Reichenbach, *The Philosophy of Time and Space* Campbell, *Measurement and Calculation*	Dirac's equation combines quantum mechanics with special relativity
1929	Carnap, Hahn and Neurath, *The Scientific World View: The Vienna Circle* Dewey, *Experience and Nature* Lewis, *Mind and the World Order*		Heisenberg and Pauli's quantum field theory Hubble's law (more distant a galaxy, faster it is receding from Earth)

	Philosophy (general)	Philosophy of science	Science and technology
1930		Heisenberg, *The Physical Principles of Quantum Theory*	Dirac, Principles of Quantum Mechanics 'Neutrino' postulated (Pauli); term coined 1932 (Fermi); discovered 1955 Discovery of planet Pluto (Tombaugh)
1931	Tarski, 'The Concept of Truth in Formalized Languages'	Neurath, 'Physicalism' Schlick, 'Causality in Contemporary Physics' Carnap, 'Die physikalische, Sprache als Universalsprache der Wissenschaft' (trans. *The Unity of Science*, 1934)	'Positron' (positively charged electron) postulated (Dirac); discovered 1932 (Anderson); first form of anti-matter discovered
1932		Joad, *Philosophical Aspects of Modern Science*	Heisenberg's model of atomic nucleus: neutrons and protons held together by exchanging electrons Discovery of neutron (Chadwick)
1933			Fermi's theory of beta decay (first suggestion of weak interaction) Meisner effect discovered (Meisner)
1934	Carnap, *The Logical Syntax of Language*	Bachelard, *The New Scientific Spirit*	
1935		Popper, *The Logic of Scientific Discovery* Eddington, *New Pathways in Science*	'Exchange particle' causing attraction between particles in atomic nucleus (strong force) proposed (Yukawa); called 'meson' (1939), now 'pion'
1936	Ayer, *Language, Truth and Logic* Schlick, 'Meaning and Verification'	Husserl, *The Crisis of European Sciences and Transcendental Phenomenology*	Bridgman, *The Nature of Physical Theory* Inauguration of *The International Encyclopedia of Unified Sciences* (Neurath, Carnap, Morris)
1937		Stebbing, *Philosophy and the Physicists*	'Muon' discovered (Anderson); initial claim to be Yukawa meson shown false 1945 (Conversi, Puncini and Picconi) Concept of 'charge conjugation' introduced

			for particle interactions (Kramers); in 1958 is shown to be invalid for some interactions
1938		Reichenbach, *Experience and Prediction* Carnap, 'Logical Foundations of the Unity of Science'	
1939	Blanshard, *The Nature of Thought*	Eddington, *The Philosophy of Physical Science*	Method of calculating properties of material objects from quantum principles developed (Herring)
1940	Russell, *An Inquiry into Meaning and Truth* Collingwood, *An Essay on Metaphysics*		
1942			Two-meson theory (Sakata and Inoué) First controlled chain reaction (Fermi) First radio map of universe (Reber)
1943	Sartre, *Being and Nothingness*		Quantum electrodynamics (QED) developed (Tomonaga)
1944		Reichenbach, *Philosophical Foundations of Quantum Mechanics*	
1946		Frank, *Foundations of Physics*	Term 'lepton' introduced for light particles not affected by strong force (Pais and Moller) 'V particle' discovered (Rochester and Butler)
1947	Carnap, *Meaning and Necessity*		'Pion' (Yukawa meson) discovered (Powell and team) Lamb Shift discovered; independent development of quantum electrodynamics (QED) four years after similar theory of Tomonaga Two-meson theory developed independently four years after similar theory of Sakata and Inoué (Marshak & Bethe)

	Philosophy (general)	Philosophy of science	Science and technology
1948			Opposed theories of the universe formulated: steady-state theory (Bond, Gold, Hayle) and Big Bang theory (Gamow, Alpher, Harmon)
1949	Schlick, *Philosophy of Nature*		Atomic nucleus not necessarily spherical (Rainwater)
1950	Strawson, 'On Referring'		
1951	Quine, 'Two Dogmas of Empiricism' Goodman, *The Structure of Appearance*		
1952		Wisdom, *Foundations of Inference in Natural Science* Hempel, *Fundamentals of Concept Formation in Empirical Science*	Bubble chamber for study of subatomic particles developed (Glaser)
1953	Wittgenstein, *Philosophical Investigations* Quine, *From a Logical Point of View*	Toulmin, *The Philosophy of Science* Braithwaite, *Scientific Explanation*	'Strangeness' quantum number introduced (Gell-Mann, Nakano and Nishijina)
1954	Ryle, *Dilemmas*	Reichenbach, *Nomological Statements and Admissable Operations*	European Centre for Nuclear Research (CERN) founded
1955			Neutrinos observed (Cowen and Reines)
1956	Reichenbach, *The Direction of Time*		Anti-neutron discovered (Cook, Lambertson, Picconi, Wentzel)
1957		Bohm, *Causality and Chance in Modern Physics*	Parity not conserved for weak interactions (Yang, Lee, Wu) 'Boson' (W particle) proposed as mediator of weak interactions (Schwinger)
1958	Polanyi, *Personal Knowledge*	Hanson, *Patterns of Discovery* Bohr, *Atomic Physics and Human Knowledge*	

1959	Strawson, *Individuals*	Bunge, *Causality*	
1960	Quine, *Word and Object*		Mossbauer effect discovered (Mossbauer); used to confirm Einstein's general theory of relativity (Pound and Reblan) 'Resonances' (short-lived particles) discovered (Alvarez)
1961		Nagel, *The Structure of Science* Harré, *Theories and Things* Capek, *Philosophical Impact of Contemporary Physics*	First human being to orbit the Earth (Gagarin)
1962	Austin, *How to do Things with Words* Black, *Models and Metaphors*	Kuhn, *The Structure of Scientific Revolutions* Sellars, *Science, Perception and Reality* Maxwell, 'The Ontological Status of Theoretical Entities' Hesse, *Models and Analogies in Science*	
1963	Popper, *Conjectures and Refutations*	Smart, *Philosophy and Scientific Realism* Grunbaum, *Philosophical Problems of Space and Time*	First recognition of a quasar (Schmidt)
1964	Scheffler, *The Anatomy of Inquiry*		Concept of 'quark' introduced (Gell-Mann)
1965		Hempel, *Aspects of Scientific Explanation*	Confirmation of Big Bang theory with accidental discovery of radio-wave remnants of Big Bang (Penzias and Wilson)
1966		Hempel, *Philosophy of Natural Science*	
1967	Davidson, 'Truth and Meaning'	Scheffler, *Science and Subjectivity*	Strong nuclear force shown to violate parity conservation (Lobashov) 'Electroweak theory' unifies weak and electromagnetic forces (Weinberg, Salam, Glashow) First pulsar discovered (Bell)

	Philosophy (general)	Philosophy of science	Science and technology
1969	Quine, *Ontological Relativity*		
1972	Popper, *Objective Knowledge*		Quantum chromodynamics (QCD) initiated (Gell-Mann) Biblical accounts of creation should receive equal attention as evolutionary theory: California State Board of Education
1973			Creation of the universe from absolutely nothing under probabilistic laws of quantum mechanics proposed (Tyron)
1974		Sklar, *Space, Time and Spacetime* Barnes, *Scientific Knowledge and Sociological Theory*	First of GUTs (grand unified theories) unifies strong, weak and electro-magnetic forces (Georgi, Glashow) J/psi particle discovered (Richter; Trug); confirmation of charm theory of quarks
1975	Dummett, *What is a Theory of Meaning?*	Feyerabend, *Against Method*	
1976		Bloor, *Knowledge and Social Imagery*	
1977		Lauden, *Progress and its Problems*	Upsilon particle discovered (Lederman): confirms quark theory of baryons
1978	Goodman, *Ways of Worldmaking*	Feyerabend, *Science in a Free Society*	
1979		Latour and Woolger, *Laboratory Life* Lakatos, *The Methodology of Scientific Research Programs*	
1980	Rorty, *Philosophy and the Mirror of Nature*	van Fraasen, *The Scientific Image*	Neutrinos may have tiny mass, thus representing 'missing mass' thought to hold galaxies together

			'Inflationary universe' model: universe expands rapidly for short time before Big Bang (Guth) Revival of 'catastrophism': collision between Earth and large body results in mass extinctions, including extinction of dinosaurs, (W. and L. Alvarez)
1981	Putnam, *Reason, Truth and History*		'New inflationary universe' theory of the origins of the universe (Linder; Albrecht and, Steinhardt)
1983		Cartwright, *How the Laws of Physics Lie* Hacking, *Representing and Intervening*	Discovery of W and Z particles; further confirms electroweak theory (CERN)
1985		Fox–Keller, *Reflections on Gender and Science*	Hole in ozone layer over Antartica discovered
1986		Harding, *The Feminist Question in Science*	Individual quantum jumps in individual atoms observed Fifth fundamental force, hypercharge, discovered (Fishbach); not universally accepted Discovery of 'Great Attractor', a point towards which a number of galaxies (including ours) are moving
1987	Feyerabend, *Farewell to Reason* Lakoff, *Women, Fire and Dangerous Things*	Latour, *Science in Action* Putnam, *The Many Faces of Realism*	US Supreme Court rejection of equal-time concept of teaching for creationism
1988		Hawking, *A Brief History of Time*	
1989			Controversy over cold-fusion experiments (production of energy through nuclear fusion at room temperature); results subsequently discredited

1913		Henry Ford's assembly line
1914	Driesch, *The History and Theory of Vitalism*	
1915		Sonar developed
1921	Insulin discovered (Banting, Best, McLeod, Collip)	
1923	C. L. Morgan, *Emergent Evolution*	
1925		First analog computer (Bush)
1926	T. H. Morgan, *The Theory of the Gene* C. L. Morgan, *Life, Mind, and Spirit*	First public demonstration of television
1928	Discovery of penicillin (Fleming); production and clinical use not until 1940s	

1929	Discovery of deoxyribose nucleic acids (DNA) Woodger, *Biological Principles*	
1930	Immunization against typhus developed (Zinsser)	
1931	Haldane, *The Philosophical Basis of Biology*	
1932	T. H. Morgan, *The Scientific Basis of Evolution*	Particle accelerator first used to split lithium atom (Cockcroft and Walton)
1933		Vitamin C synthesized
1935		Richter scale developed (Richter) First radar developed (Watson, Watt)
1936	Isolation of DNA in pure state (Belozersky)	Primitive digital computer (Zuse) ABC (Atanasoff-Berry Computer), first electronic computer begun; completed 1939; operational version 1942
1937	Woodger, *The Axiomatic Method in Biology*	
1938	Oparin, *The Origin of Life*	Uranium atom first split (Hahn)
1939		DDT insecticide synthesized (Muller)
1940	Penicillin developed as antibiotic (term 'antibiotic' coined 1941)	
1941		Zuse's Z2 computer: electromagnetic relays and punched tape for data entry
1943		First all-electronic computer, 'Colossus', developed to crack codes (Turing) First operational nuclear reactor (Oak Ridge, TN)

	Biology	Technology
1944	DNA determined as hereditary material for almost all living beings (Avery)	Jet-engine (V-1) and rocket-propelled (V-2) bombs
1945	Lille, *General Biology and Philosophy of the Organism*	Atomic bombs dropped on Hiroshima and Nagasaki ENIAC: first all-purpose, stored-program electronic computer
1946		Radioactive carbon-14 method developed for dating objects (Libby)
1948	Woodger, *Biological Principles*	Discovery of transistor (Shockley, Brattain, Burdeen); will replace vacuum tubes
1950	Sommerhoff, *Analytical Biology*	
1951	Bernal, *The Physical Basis of Life*	UNIVAC I, first commercially available computer Heart-lung machine developed (Gibson)
1952	Plasmid (structure containing genetic material exchanged by bacteria) discovered (Lederberg)	Hydrogen bomb ('H Bomb') developed (Teller)
	Polio vaccine developed (Salk); mass innoculation in 1954; superceded by new vaccine in 1957 (Sabine) Woodger, *Biology and Language*	First nuclear reactor accident (Chalk River, Canada)
1953	Double-helix structure of DNA determined (Crick and Watson)	
1955		FORTRAN, first computer-programming language (Backus, IBM) LISP, computer language of artificial intelligence developed (McCarthy)

1957		Sputnik I, first artificial satellite, launched by USSR
1958		Integrated circuit invented
1960		First laser (Maiman); precursors are Townes' maser (1954), Kastler's 'optical pumping' (1950)
1961	RNA code producing amino acid in cell discovered	First human being in space (Gagarin)
1962	Carson, *Silent Spring* (environmentalist classic)	Disk storage for computer data introduced (IBM)
1964		'Green Revolution' inaugurated with strain of rice generating double yield given sufficient fertilizer
1967		Keyboards used for computer data entry
1968	Discovery of restrictive enzymes (can cut DNA of virus at particular point); would become a basic tool of genetic engineering Becker, *The Biological Way of Thought*	
1969	Single gene first isolated (Beckwith)	First human beings on the moon (Armstrong and Aldrin) First artificial heart used in a human being
1970	First complete synthesis of a gene	
1971	Monod, *Chance and Necessity*	Microprocessor (chip) introduced
1972		CAT-scan (computerized axial tomography) introduced for medical work
1973	Beginning of genetic engineering (Cohen and Boyer)	First Skylab launched

	Biology	Technology
1975		Personal computers introduced (Altair 8800)
1976	Functional synthetic gene constructed (Khorana)	
1977	Earliest known cases of AIDS; disease not recognized until 1981	Apple II personal computer introduced
1978	First 'test-tube' baby (Leslie Brown)	
1979		Partial meltdown of nuclear reactor at Three Mile Island
1980	Bohm, *Wholeness and the Implicate Order*	
1981	First transferrence of genes from one animal to another of a different species	First flight of space shuttle Columbia
1982	First commercial product of genetic engineering (human insulin)	
1984	Baboon heart implanted in human baby	
1984	Genetic fingerprinting technique developed	
1986	First field trials of genetically engineered organisms (tobacco)	Explosion of space shuttle Challenger Chernobyl nuclear reactor explosion
1987		'Warm temperature' superconductor discovered
1989		Exxon-Valdez oil tanker spill off the coast of Alaska

Introduction

S.G.Shanker

In this volume we survey the striking developments that have taken place in the philosophies of logic, mathematics and science in the twentieth century. The very use of a genitive case here bears eloquent testimony to the dramatic changes that have occurred. Prior to this century, few philosophers troubled to break 'philosophy' down into its constituent parts. Nor did they display any pronounced interest in the nature of philosophy *per se,* or the relation in which philosophy stands to science. Indeed, subjects that we now regard as totally distinct from philosophy—such as mathematics or psychology, and even physics or biology—were once all located within the auspices of philosophy.

It is interesting to note, for example, how Hilbert obtained his doctorate from the philosophy department. Now we are much more careful to distinguish between axiomatics, proof theory, categorization theory, the foundations of mathematics, mathematical logic, formal logic, and the philosophy of mathematics. That hardly means that philosophers are only active in the latter areas, however, while mathematicians get to rule over the former. Rather, philosophers and mathematicians move about freely in all these fields. To be sure, it is always possible to distinguish between the work of a mathematician and that of a philosopher: the approach, the techniques, and most especially the intentions and the conclusions drawn, invariably betray the author's occupation. But the fact that philosophers and mathematicians are working side-by-side, that they are reading each other's work and attending each other's conferences, is an intellectual development whose significance has yet to be fully absorbed.

Significantly, the major figures in the philosophies of logic and mathematics this century—Frege, Russell, Wittgenstein, Brouwer, Poincaré, Hilbert, Gödel, Tarski, Carnap, Quine—all moved from logic or mathematics to philosophy. Perhaps more than any single factor, it was

this dynamic that determined the nature of analytical philosophy. For it resulted not only in the importation of formal tools but also in the preoccupation with 'logical analysis', in the search for 'regimentation' and the preoccupation with the construction of 'formal models' of language. Increasingly, an undergraduate education in philosophy began not with the writings of Plato and Aristotle but with the propositional and predicate calculus. Where students were once exposed to the subtle nuances in the concept of truth, they were now trained in the art of axiomatizing the concept of truth. Symposia and dialogues were supplanted by truth tables and the turgid prose of late nineteenth-century German scientific writing.

Perhaps the most noticeable effect of this overwhelming logical and mathematical presence is that philosophical arguments began to be conducted at a very high level of technical sophistication. Those who came to these issues straight from philosophy found themselves forced to master the intricacies of formal or mathematical logic if they wished to participate in the debates. But for all the changes taking place, the underlying philosophical problems remained remarkably constant. Questions such as 'What is the nature of truth?', 'What is the nature of proof?', 'What is the nature of concepts?', 'What is the nature of inference?', or even that much-vaunted issue of analytic philosophy, 'What is the nature of meaning?', have all long been the loci of philosophical interest. Thus, it is not surprising that over the past few years there has been a remarkable surge in historical studies, all motivated by the goal of establishing the relevance of some classical figure or argument for contemporary thought—as Professor Parkinson and I point out in our general introduction to this *History*.

Still, it would be imprudent to conclude from the perennial nature of its problems that philosophy has not in fact changed in some fundamental way this century. It is not so much the pervasive influence of formal and formalist thought (which may in fact already be starting to wane), however, as the relation in which philosophy now stands to science. This issue has been a pre-eminent concern throughout this century: indeed, in some ways, it has been a defining issue for the aspiring philosopher of logic, mathematics, or science.

The two main rival positions have been the Russellian and the Wittgensteinian: scientism, and what has been dubbed (by its critics at any rate) ordinary language philosophy. According to Russell, philosophy should 'seek to base itself upon science': it should 'study the methods of science, and seek to apply these methods, with the necessary adaptations, to its own peculiar province'.[1] There are two basic aspects of scientism as conceived by Russell. First, there is no intrinsic difference between philosophy and science: each is engaged in the pursuit of knowledge (albeit at different levels of generality); each constructs theories and

generates hypotheses. Second, philosophy plays a heuristic role in the evolution of science. As Russell saw it,

> To a great extent, the uncertainty of philosophy is more apparent than real: those questions which are already capable of definite answers are placed in the sciences, while those only to which, at present, no definite answer can be given, remain to form the residue which is called philosophy.[2]

On this picture, the realm of philosophy is constantly being eroded. The more effective philosophers are, the more imminent becomes their demise. For their success entails the active engagement of scientists, rigorously testing and revising the theories that originated in a priori reasoning.

The appeal of Russell's argument stemmed largely from the fact that he had history on his side. The pattern was set in the mechanist/ vitalist debates: in the removal of first the animal heat debate and then the reflex theory debate from the province of philosophy and their resolution in physiology. It was natural for scientistic philosophers to assume that Turing's mechanical version of Church's thesis had set the stage for yet another major step in this process: i.e. the transference of the mind from philosophy's jurisdiction to that of cognitive science. The sentiment began to surface that one could no longer regard philosophy as the driving force behind logical, mathematic and scientific progress. Rather, the feeling was that the 'Queen of the Sciences' had been reduced to the role of handmaiden, initiating perhaps but in no way governing the great advances taking place in logic, mathematics and science. To borrow a term from contemporary concept theory, the fate of philosophy in the twentieth century began to be characterized as the descent from superordinate, to basic-level, to subordinate status.

On the face of it, this argument is rather curious. After all, it takes as its paradigm the displacement of natural philosophy by physics. But the philosophical debates that have been inspired by physics in the twentieth century are amongst the most profound and spirited that philosophy has ever enjoyed. Disputes over the nature of matter and time, the origin of the universe, the nature of experiment, evidence, explanation, laws and theory, the relation of physics to the other sciences: these are but a few of the issues which have been hotly debated this century, and which will continue to stimulate intense debate. And these pale in comparison to the controversies sparked off by Turing's thesis.

If anything, interest in philosophy has grown throughout this century, as is manifest by the rapid growth of philosophy faculties in every liberal arts programme. Like the relation of the Canadian economy to the American, the more science has advanced, the more philosophy has

grown. New scientific breakthroughs—indeed, new sciences—seem to create in their wake a host of new philosophical problems. But then the crucial question which this raises, which the scientistic conception of philosophy obscures, is: what renders these problems *philosophical*? Is it just that they arise at a premature scientific stage, before there is an adequate theory to deal with them? But if that were the case, how could we speak of there being *perennial* philosophical problems?

Wittgenstein sought to come to terms with this latter question throughout his later writings. In 1931 he wrote:

> You always hear people say that philosophy makes no progress and that the same philosophical problems which were already proccupying the Greeks are still troubling us today. I read: '… philosophers are no nearer to the meaning of "Reality" than Plato got,…'. What a strange situation. How extraordinary that Plato could have even got as far as he did! Or that we could not get any further! Was it because Plato was so *extremely* clever?[3]

Wittgenstein's proposed explanation for this phenomenon—viz., 'The reason is that our language has remained the same and always introduces us to the same questions' (Ibid.)—drew from Russell the bitter complaint that this would render philosophy 'at best, a slight help to lexicographers, and at worst, an idle tea-table amusement.'[4] But this criticism rests on a profound misreading of Wittgenstein's conception of the nature of philosophy. Indeed, the very assumption that the philosophers whom Russell cites in *My Philosophical Development* (viz., Wittgenstein, Ryle, Austin, Urmson and Strawson) can be identified as forming a philosophical 'school' is deeply suspect. Admittedly, they all shared certain fundamental attitudes towards the proper method of resolving philosophical problems, but in no way did they all share the same philosophical interests and objectives, let alone subscribe to a common set of philosophical doctrines or theses.

The basic premiss Wittgenstein was advancing is that questions about the nature of concepts belong to logic, and that we clarify the nature of a concept by surveying the manner in which the concept-word is used or learnt. Russell attributed to Wittgenstein the view that philosophical problems can be resolved by studying the ordinary grammar of concept-words. But nothing could be further from the truth. The fundamental principle underlying Wittgenstein's argument is that the source of a philosophical problem often lies in a crucial and often elusive difference between the *surface grammar* of a concept-word and its *depth* or *logical grammar,* or in the philosopher's tendency to treat what are disguised *grammatical propositions* as if they were empirical propositions.

Where Russell was certainly right, however, was in thinking that the later Wittgenstein was fundamentally opposed to the scientistic conception of philosophy. In his 1930 lectures Wittgenstein announced:

> What we find out in philosophy is trivial; it does not teach us new facts, only science does that. But the proper synopsis of these trivialities is enormously difficult, and has immense importance. Philosophy is in fact the synopsis of trivialities.[5]

This means that the task of philosophy is to clarify concepts and theories, not to draw inductive generalizations or to formulate theses. Indeed, Wittgenstein went so far as to insist, 'The philosopher is not a citizen of any community of ideas. That is what makes him into a philosopher.'[6] Wittgenstein did not mean to suggest by this that philosophy does not have a crucial role to play *vis-à-vis* science. In the *Bouwsma Notes* he remarks that 'the consummation of philosophy' in the twentieth century might very well lie in the clarification of scientific theories: in 'work which does not cheat and where the confusions have been cleared up'.[7] But this would seem to limit philosophy to the task of interpreting scientific prose: the 'history of evolving ideas', as it were. And as the following chapters demonstrate, the philosophies of logic, mathematics and science this century took *Principia Mathematica* not *The A.B.C of Relativity* as their standard-bearer.

What's more, there is a real danger in this thought that the principal role of philosophy is to describe and not explain. For it has a tendency to promote the view that philosophers are armchair critics, akin to theatre critics, both professionally and temperamentally set apart from the scientific writings whose shortcomings it is their chief job to expose. Not surprisingly, one frequently hears the complaint from scientists that philosophers have been seduced by the negative: that they criticize a theory without appreciating the subtle difficulties involved, or without making the necessary effort to master the literature underpinning a scientific issue. Yet philosophers, even scientistic philosophers, are in no rush to lose their distinctive identity. There has thus been marked hostility and frustration on both sides of the 'philosophy versus science' divide.

These are important emotions. For if philosophy were irrelevant to the ongoing development of logic, mathematics and science, there would be neither anger nor impatience: only disinterest. But one constantly hears the demand from scientists for positive philosophical input. So the question which this naturally raises is, what is impeding this union? Is it perhaps the very terms in which twentieth-century philosophy has tried to assess its relation to science? Is it not significant that both scientism and ordinary language philosophy have strong nineteenth-century roots: the former in scientific materialism and the latter in hermeneutics? Indeed, is

not the battle between scientism and ordinary language philosophy reminiscent—and perhaps simply a continuation—of the battle between scientific materialism and hermeneutics? If there has not been a decisive victory by either side, is it, perhaps, because each is articulating an important truth: and, perhaps, omitting an important aspect of the development of the philosophy of logic, mathematics and science this century?

We can turn again to Wittgenstein to appreciate this point. At the close of the second book of *Philosophical Investigations* Wittgenstein remarks how, 'in psychology there are experimental methods and *conceptual confusion*… The existence of the experimental method makes us think we have the means of solving the problems which trouble us; though problem and method pass one another by'.[8] Ironically, a few cognitivists actually greeted Wittgenstein's censure as confirming the importance of the post-computational revolution. For example, F.H. George insisted that:

> [Wittgenstein's] criticism of experimental psychology, at the time it was made, [was] almost entirely justified. Experimental psychologists were, at that time, struggling to unscramble their concepts and clarify their language and models: at worst they believed that as long as a well-controlled experiment was carried out, the mere accumulation of facts would make a science. The relation, so vital to the development of psychology, between experimental results, by way of interpretation and explanatory frameworks, models, used largely to be neglected.[9]

On this reading, the mechanist paradigm that Wittgenstein was attacking was fundamentally displaced by Turing's version of Church's thesis. Hence, Wittgenstein's concerns are now hopelessly dated for:

> Almost everyone now acknowledges that theory and experiment, model making, theory construction and linguistics all go together, and that the successful development of a science of behavior depends upon a 'total approach' in which, given that the computer 'is the only large-scale universal model' that we possess, 'we may expect to follow the prescription of Simon and construct our models—or most of them—in the form of computer programs'.[10]

Ignoring his enthusiasm here for the post-computational mechanist revolution, what is most intriguing about George's interpretation of Wittgenstein's argument is the manner in which he seeks to synthesize scientism with ordinary language philosophy. On this argument, philosophy enters a scientific enterprise at its very beginnings; it serves an

important role in clearing away the confusions inhibiting the construction of a comprehensive explanatory framework. But once the new model is in place, philosophy has no further constructive role to play. For, as George puts it, 'much of this conceptual confusion has now disappeared'.[11]

Is this really the case? Has philosophy been even more successful than Russell envisaged? The philosophies of logic, mathematics and science have been driven by five leading problems this century:

1 What is the nature of logic, of logical truth?
2 What is the nature of mathematics: of mathematical propositions, mathematical conjectures, and mathematical proof?
3 What is the nature of formal systems, and what is their relation to what Hilbert called 'the activity of understanding'?
4 What is the nature of language: of meaning, reference, and truth?
5 What is the nature of mind: of consciousness, mental states, mental processes?

I have limited these to five problems to suggest a generational flux. A few philosophers have, of course, been active in all these areas throughout the century, but there is some basis for viewing the development of the philosophies of logic, mathematics and science in the twentieth century in terms of the succession of these five leading problems.

Now, very few philosophers would be willing to consign any, let alone all five, of these problems to the 'History of Ideas'. What the following chapters reveal is not the resolution of these issues, but the deepening understanding we have achieved of the nature of logic, mathematics, language and cognition. Moreover, as the century has progressed, it has become increasingly tenuous to suppose that philosophy is either conceptually prior to science, i.e., that philosophy clears away the confusions so that the proper business of theory-making can proceed—or that philosophy is conceptually posterior to science, i.e., that philosophy is restricted to correcting the errors that occur in scientific prose. For the advances that have been realized in the topics covered in this volume are not simply the result of philosophical reflection, or well-controlled experiments, but rather, are the outcome of a complex interplay of philosophic and scientific techniques as practised by both philosophers and scientists.

Thus, each of the chapters in this volume is as important to science students as the relevant science textbooks are to philosophy students. The point here is not that the categorial difference between philosophy and science—between philosophical and empirical problems, or philosophical and empirical methods—is disappearing, but that the formal, or institutional demarcation of these activities is fast becoming obsolete. All over the world interdisciplinary units are springing up which are

specifically designed to train their students in various cognitive sciences as well as in philosophy. This is a reflection of the fact that scientists themselves are constantly engaged in conceptual clarification, while philosophers have grasped the importance of entering fully into the community of science if their efforts are to serve the needs of scientists. What has been consigned to the 'History of Ideas' are the old terms of the 'philosophy versus science' debate. But the following chapters are not just history; more fundamentally, they are a harbinger of the great changes we can continue to expect in the ongoing evolution of philosophy.

CHAPTER 1

Philosophy of logic

A.D.Irvine

The relationship between evidence and hypothesis is fundamental to the advancement of science. It is this relationship—referred to as the relationship between premisses and conclusion—which lies at the heart of logic. Logic, in this traditional sense, is the study of correct inference. It is the study of formal structures and non-formal relations which hold between evidence and hypothesis, reasons and belief, or premisses and conclusion. It is the study of both conclusive (or monotonic) and inconclusive (non-monotonic or ampliative) inferences or, as it is also commonly described, the study of both entailments and inductions. Specifically, logic involves the detailed study of formal systems designed to exhibit such entailments and inductions. More generally, though, it is the study of those conditions under which evidence rightly can be said to justify, entail, imply, support, corroborate, confirm or falsify a conclusion.

In this broad sense, logic in the twentieth century has come to include, not only theories of formal entailment, but informal logic, probability theory, confirmation theory, decision theory, game theory and theories of computability and epistemic modelling as well. As a result, over the course of the century the study of logic has benefited, not only from advances in traditional fields such as philosophy and mathematics, but also from advances in other fields as diverse as computer science and economics. Through Frege and others late in the nineteenth century, mathematics helped transform logic from a merely formal discipline to a mathematical one as well, making available to it the resources of contemporary mathematics. In turn, logic opened up new avenues of investigation concerning reasoning in mathematics, thereby helping to develop new branches of mathematical research—such as set theory and category theory—relevant to the foundations of mathematics itself.

Similarly, much of twentieth-century philosophy—including advances in metaphysics, epistemology, the philosophy of mathematics, the philosophy of science, the philosophy of language and formal semantics—closely parallels this century's logical developments. These advances have led in turn to a broadening of logic and to a deeper appreciation of its application and extent. Finally, logic has provided many of the underlying theoretical results which have motivated the advent of the computing era, learning as much from the systematic application of these ideas as it has from any other source.

This chapter is divided into four sections. The first, 'The Close of the Nineteenth Century', summarizes the logical work of Boole, Frege and others prior to 1900. The second, 'From Russell to Gödel', discusses advances made in formal logic from 1901, the year in which Russell discovered his famous paradox, to 1931, the year in which Gödel's seminal incompleteness results appeared. The third section, 'From Gödel to Friedman', discusses developments in formal logic made during the fifty years following Gödel's remarkable achievement. Finally, the fourth section, 'The Expansion of Logic', discusses logic in the broader sense as it has flourished throughout the latter half of the twentieth century.

THE CLOSE OF THE NINETEENTH CENTURY

'Logic is an old subject, and since 1879 it has been a great one.'[1] This judgment appears as the opening sentence of W.V.Quine's 1950 *Methods of Logic*. The sentence is justly famous—even if it has about it an air of exaggeration—for nothing less than a revolution had occurred in logic by the end of the nineteenth century.

Several important factors led to this revolution, but without doubt the most important of these concerned the mathematization of logic. Since the time of Aristotle, logic had taken as its subject matter formal patterns of inference, both inside and outside mathematics. Aristotle's *Organon* had been intended as nothing less than a tool or canon governing correct inference. However, it was not until the mid-nineteenth century that logic came to be viewed as a subject which could be developed mathematically, alongside other branches of mathematics. The leaders in this movement—George Boole (1815–64), Augustus DeMorgan (1806–71), William Stanley Jevons (1835–82), Ernst Schröder (1841–1902), and Charles Sanders Peirce (1839–1914)—all saw the potential for developing what was to be called an 'algebra of logic', a mathematical means of modelling the abstract laws governing formal inference. However, it was not until the appearance, in 1847, of a small pamphlet entitled *The Mathematical Analysis of Logic,* that Boole's calculus of

classes—later extended by Schröder and Peirce to form a calculus of relations—successfully achieved this end.

Boole had been prompted to write *The Mathematical Analysis of Logic* by a public dispute between DeMorgan and the philosopher William Hamilton (1788–1856) over the quantification of the predicate. As a result, Boole's landmark pamphlet was the first successful, systematic application of the methods of algebra to the subject of logic. So impressed was DeMorgan that two years later, in 1849, despite Boole's lack of university education, he was appointed Professor of Mathematics at Queen's College, Cork, Ireland, largely on DeMorgan's recommendation. Five years following his appointment, Boole's next work, *An Investigation of the Laws of Thoughts,* expanded many of the ideas introduced in his earlier pamphlet. In the *Laws of Thought,* Boole developed more thoroughly the formal analogy between the operations of logic and mathematics which would help revolutionize logic. Specifically, his algebra of logic showed how recognizably algebraic formulas could be used to express and manipulate logical relations.

Boole's calculus, which is known today as the theory of Boolean algebras, can be viewed as a formal system consisting of a set, S, over which three operations, $\cap$ (or $\times$, representing intersection), $\cup$ (or +, representing union), and ' (or -, representing complementation) are defined, such that for all a, b, and c that are members of S, the following axioms hold:

(1) Commutativity:
$a \cap b = b \cap a$, and $a \cup b = b \cup a$

(2) Associativity:
$a \cap (b \cap c) = (a \cap b) \cap c$, and $a \cup (b \cup c) = (a \cup b) \cup c$

(3) Distributivity:
$a \cap (b \cup c) = (a \cap b) \cup (a \cap c)$, and $a \cup (b \cap c) = (a \cup b) \cap (a \cup c)$

(4) Identity:
There exist two elements, 0 and 1, of S such that, $a \cup 0 = a$, and $a \cap 1 = a$

(5) Complementation:
For each element a in S, there is an element a' such that $a \cup a' = 1$, and $a \cap a' = 0$.

The logical utility of the system arises once it is realized that many logical relations are successfully formalizable in it. For example, by letting a and b represent variables for statements or propositions, $\cap$ represent the truth-functional connective 'and', and $\cup$ represent the truth-functional connective 'or', the commutativity axioms assert that statements of the form 'a and b' are equivalent to statements of the form 'b and a', and that

statements of the form '*a* or *b*' are equivalent to statements of the form '*b* or *a*'. Similarly, by letting ' represent truth-functional negation, the complementation axioms assert that for each statement, *a*, there is a second statement, not-*a*, such that the statement '*a* or not-*a*' is true and the statement '*a* and not-*a*' is false. A similar interpretation (which identifies electronic gates with Boolean operators) provides the foundation for the theory of switching circuits. Thus, by 1854 the mathematization of logic was well under way.

A second important factor concerning the advancement of logic during this period had to do, not with the mathematization of logic, but with the logicizing of mathematics. The idea of reducing mathematics to logic had been advocated first by Gottfried Wilhelm Leibniz (1646–1716) and later by Richard Dedekind (1831–1916). In general, it amounted to a two-part proposal: first, that the concepts of (some or all branches of) mathematics were to be defined in terms of purely logical concepts and, second, that the theorems of (these same branches of) mathematics were in turn to be deduced from purely logical axioms. However, it was not until the late nineteenth century that the logical tools necessary for attempting such a project were discovered.

Not accidentally, the attempt to logicize mathematics coincided with a process of systematizing and rigorizing mathematics generally. Many commentators had called for such work to be done. Earlier discoveries by Gerolamo Saccheri (1667–1733), Karl Gauss (1777–1855), Nikolai Lobachevski (1793–1856), János Bolyai (1802–60) and Bernhard Riemann (1826–66) in the development of non-Euclidean geometry had led to a new sensitivity about axiomatics and about foundations generally. Thus, by the late 1800s, the critical movement—which had begun in the 1820s—had eliminated many of the contradictions and much of the vagueness contained in many early nineteenth century mathematical theories. Bernard Bolzano (1781–1848), Niels Abel (1802–29), Louis Cauchy (1789–1857) and Karl Weierstrass (1815–97) had successfully taken up the challenge of rigorizing the calculus. Weierstrass, Dedekind and Georg Cantor (1845–1918) had all independently developed methods for founding the irrationals in terms of the rationals and, as early as 1837, William Rowan Hamilton (1805–65) had introduced ordered couples of reals as the first step in supplying a logical basis for the complex numbers. By 1888, Dedekind had also developed a consistent postulate set for axiomatizing the set of natural (or counting) numbers, *N*. Building upon these results, as well as others by H.G.Grassmann (1809–77), Guiseppe Peano (1858–1932) was then able to develop systematically, not just a theory of arithmetic and of the rationals, but a reasonably detailed theory of real limits as well. The results appeared in Peano's 1889 *Arithmetics Principia*.

Beginning with four axioms governing his underlying logic, and the five (now famous) Peano postulates first introduced by Dedekind, Peano

defined the set of natural numbers as a series of successors to the number zero. Letting '0' stand for zero, *'s(x)'* stand for the successor of *x*, and *'N'* stand for the set of natural numbers, the non-logical postulates may be listed as follows:

(1) Zero is a number:
$$o \in N$$
(2) Zero is not the successor of any number:
$$\sim(\exists x)(x \in N \,\&\, s(x) = o)$$
(3) The successor of every number is a number:
$$(\forall x)(x \in N \rightarrow s(x) \in N)$$
(4) No two distinct numbers have the same successor:
$$(\forall x)(\forall y)(((x \in N \,\&\, y \in N) \,\&\, x \neq y) \rightarrow s(x) \neq s(y))$$
(5) The Principle of Mathematical Induction, that if zero has a property, *P*, and if whenever a number has the property its successor also has the property, then all numbers have the property:
$$(\forall P)(((P(o) \,\&\, (\forall x)((x \in N \,\&\, Px) \rightarrow Ps(x)))) \rightarrow (\forall y)(y \in N \rightarrow Py)).$$

Thus, beginning with a few primitive notions, it was in principle possible to derive almost all of mathematics in a rigorous, coherent fashion. Despite this, the task of formally relating most of logic to mathematics remained virtually unadvanced since the time of Boole.

Crucial to further advancement was the introduction of the quantifiers and the development of the predicate calculus. The introduction of the quantifiers resulted from the independent work of several authors, including Peirce and Schröder, but predominantly it came about through the work of Gottlob Frege (1848–1925). It is possible that Peirce was the first to arrive at the notion of a quantifier, although explicit mention of either the universal or the existential quantifier does not appear in his published writings until 1885. Frege, in contrast, first published his account in 1879 in his now famous *Begriffsschrift* (meaning literally 'concept writing'). Hence the date in Quine's famous aphorism. Subtitled 'a formula language, modeled upon that of arithmetic, for pure thought', the *Begriffsschrift* took as its goal nothing less than a rigorization of proof itself. Said Frege,

> My intention was not to represent an abstract logic in formulas, but to express a content through written signs in a more precise and clear way than it is possible to do through words. In fact, what I wanted to create was not a mere *calculus ratiocinator* but a *lingua characterica* in Leibniz's sense.[2]

The result was the introduction of a very general symbolic language

suitable for expressing the type of formal inferences used in mathematical proofs. By combining expressions representing individuals and predicates (properties and relations) with the prepositional connectives ('and', 'or', 'not', etc.) and quantifiers ('all', 'some'), Frege succeeded in producing a language powerful enough to express even the most complicated of mathematical statements. Frege immediately put his language to work, applying it as he did to his project of logicizing arithmetic. By the time his *Die Grundlagen der Arithmetik* appeared in 1884, Frege had arrived at the appropriate logical definitions for the necessary arithmetical terms and had begun work on the essential derivations. The derivations themselves appeared in his two-volume *Grundgesetze der Arithmetik* in 1893 and 1903. Thus, it is Frege, along with Boole, who is generally credited as being one of the two most important founders of modern formal logic.

The *Begriffsschrift* was Frege's first work in logic, but it is a landmark one, for in it he develops the truth-functional prepositional calculus, the theory of quantification (or predicate calculus), an analysis of propositions in terms of functions and arguments (instead of in terms of subject and predicate), a definition of the notion of mathematical sequence and the notion of a purely formal system of derivation or inference. Of these contributions, Frege's unique insight with regard to the predicate calculus was to note the inadequacy of the traditional subject/predicate distinction, and to replace it with one from mathematics, that of function and argument. For Frege, once arguments have been substituted into the free variables of a prepositional function, a judgement is obtained. In short, a word in a statement which can be replaced by other words is itself an argument, while the remainder of the sentence is the function. The fact that the *Begriffsschrift* additionally contains the first formally adequate notation for quantification, together with the first successful formalization of first-order logic, has guaranteed it a position of unique importance in the history of logic.

Unfortunately, for much of his life, Frege's work was met with indifference or hostility on the part of his contemporaries. Response to the *Begriffsschrift* was typified by a rather caustic review by Cantor, who had not even bothered to read the book. Frege's axioms for the propositional calculus (which use negation and material implication as primitive connectives) turned out not to be independent and, in addition to his one stated rule of inference, detachment (also called *modus ponens,* the rule that given well-formed formulas of the form p and $p \rightarrow q$, one can infer a well-formed formula of the form q), an unstated rule of substitution was also used. However, the most important reason for the *Begriffsschrift's* poor reception was the difficulty of working with Frege's rather idiosyncratic and cumbersome logical notation, which has not survived. Thus, it was not until others were able to replace Frege's

notation, and further rigorize his logic, that Frege's discoveries began to receive the prominence they deserved. None the less, it is Frege's analysis of propositions into functions and arguments, along with his introduction of the quantifiers, which to this day remain at the heart of the development of modern logic.

Yet a third factor contributing to the revolutionary advancement of logic during the late nineteenth century was Cantor's discovery of set theory. Intuitively, a set can be thought of as any collection of well-defined distinct objects. In Cantor's words, by the idea of a set 'we are to understand any collection into a whole *M* of definite and separate objects *m* of our intuition or our thought'.[3] The objects which determine each set are called the elements or members of that set. The symbol '$\in$' is used regularly to denote the relation of membership or elementhood. Thus '$m \in M$' is read '*m* is an element (or member) of *M*' or '*m* belongs to *M*'. Two sets are identical if and only if they contain exactly the same elements; thus, if $A=\{1, 2, 3\}$ and $B = \{+\sqrt{1}, +\sqrt{9}, +\sqrt{4}\}$, then $A=B$.

With little more than these beginnings, Cantor was able to show that the cardinality of the set of all subsets of any given set (i.e. the power set of that set) is always greater than that of the set itself, thus introducing the modern hierarchy of sets. In addition, he showed that the set of real numbers is non-denumerable (or, equivalently, that the cardinality of the continuum of reals, *R*, is greater than that of *N*). Cantor proved both results in 1891 by means of a diagonal argument, an argument designed to construct objects, on the basis of other objects, and in such a way that the new objects are guaranteed to differ from the old. Cantor's diagonal argument therefore provides an important example of a modern impossibility proof since, by using it, he proved the non-denumerability of the reals by showing that a one-to-one correspondence between the natural numbers and the reals is impossible. It also followed from Cantor's work that infinite sets could consistently be placed in one-to-one correspondence with proper subsets of themselves, thus disproving Euclid's general axiom that the whole is necessarily greater than the part. Such unintuitive results meant that set theory, like non-Euclidean geometry before it, would soon lead to further questions about the nature of proof. The question of when to rely upon axioms which, up until this point had still regularly been based upon 'clear and distinct ideas', therefore became crucial. The fact that there was also an intuitive identity between the extension of a predicate and its corresponding set meant that developments in set theory were bound to affect logic.

FROM RUSSELL TO GÖDEL

If it is fair to say that by the end of the nineteenth century logic had become invigorated as a result of its connections with mathematics, it is also fair to say that mathematics was becoming similarly invigorated as a result of its connections with logic. In fact, it was the interplay between logic and mathematics which led a host of figures in both disciplines—including most famously David Hilbert (1862–1943), L.E. J.Brouwer (1881–1966), Arend Heyting (1898–1980), A.N.Whitehead (1861–1947), Bertrand Russell (1872–1970), Ernst Zermelo (1871–1953), Kurt Gödel (1906–78), Alfred Tarski (1902–83), Alonzo Church (b. 1903) and W.V.Quine (b. 1908)—to concentrate their efforts upon foundational issues in logic and mathematics. Many were prompted to do so as a result of a problem which affected both logic and mathematics equally, the problem of the antinomies.

In 1900 many of the world's best philosophers met to attend the Third International Congress of Philosophy, held in Paris from 1 to 5 August. Following the Congress, a significant number of philosophers remained in Paris for the Second International Congress of Mathematicians, which was being held immediately afterwards, from 6 to 12 August. It was at these later meetings that Hilbert delivered his famous keynote address welcoming the mathematical world to Paris. Conscious of his place in history, Hilbert took the occasion to remind his audience of the challenges facing them as they entered a new century:

> If we would obtain an idea of the probable development of mathematical knowledge in the immediate future, we must let the unsettled questions pass before our minds and look over the problems which the science of to-day sets and whose solution we expect from the future. To such a review of problems the present day, lying at the meeting of the centuries, seems to be well adapted… However unapproachable these problems may seem to us and however helpless we stand before them, we have, nevertheless, the firm conviction that their solution must follow by a finite number of purely logical processes… This conviction of the solvability of every mathematical problem is a powerful incentive to the worker. We hear within us the perpetual call: There is the problem. Seek its solution. You can find it by reason, for in mathematics there is no *ignorabimus*.[4]

To emphasize his challenge, Hilbert presented his now famous list of twenty-three major unsolved logical and mathematical problems. First on Hilbert's list was Cantor's continuum problem, the problem of determining whether there is a set with cardinality greater than that of the

natural numbers but less than that of the continuum. Second on the list, but equally important from the point of view of the logician, was the problem of proving an axiom set consistent or, as Hilbert put it, the problem of the 'compatibility of the arithmetical axioms'. Although primarily of theoretical interest in 1900, it was a problem which would, within the year, take on new urgency.

It was also at these meetings that Russell met Peano. By all accounts the meeting was a congenial one. As Russell reports:

> The Congress was a turning point in my intellectual life, because I there met Peano. I already knew him by name and had seen some of his work, but had not taken the trouble to master his notation. In discussions at the Congress I observed that he was always more precise than anyone else, and that he invariably got the better of any argument upon which he embarked. As the days went by, I decided that this must be owing to his mathematical logic.[5]

Thus, impressed by Peano and his logic, Russell returned to England, motivated to begin work on his *Principles of Mathematics* and confident that any problem he might set for himself would quickly be solved. As one might guess, Russell's *Principles* was to be heavily influenced, not only by Peano's *Arithmetices Principia,* but also by Frege's *Begriffsschrift* and *Grundlagen*. Russell finished the first draft of the manuscript, as he tells us, 'on the last day of the century', 31 December 1900.[6]

Five months later, in May 1901, Russell discovered his now famous paradox. The paradox comes from considering the set of all sets which are not members of themselves, since this set must be a member of itself if and only if it is not a member of itself. As a result, one must attempt to find a principled way of denying the existence of such a set. Cesare Burali-Forti (1861–1931), an assistant to Peano, had discovered a similar antinomy in 1897 when he had observed that since the set of ordinals is well-ordered, it therefore must have an ordinal. However, this ordinal must be both an element of the set of ordinals and yet greater than any ordinal in the set. Hence the contradiction.[7]

After worrying about the difficulty for over a year, Russell wrote to Frege with news of the paradox on 16 June 1902. The antinomy was a crucial one, since Frege claimed that an expression such as *f(a)* could be considered to be both a function of the argument *f* and a function of the argument *a*. In effect, it was this ambiguity which allowed Russell to construct his paradox within Frege's logic. As Russell explains:

> this view [that *f(a)* may be viewed as a function of either *f* or of *a*] seems doubtful to me because of the following contradiction. Let *w* be the predicate: to be a predicate that cannot be predicated of

> itself. Can *w* be predicated of itself? From each answer its opposite follows. Therefore we must conclude that *w* is not a predicate. Likewise there is no class (as a totality) of those classes which, each taken as a totality, do not belong to themselves. From this I conclude that under certain circumstances a definable collection does not form a totality.[8]

Russell's letter to Frege, in effect telling him that his axioms were inconsistent, arrived just as the second volume of his *Grundgesetze* was in press. (Other antinomies were to follow shortly, including those discovered by Jules Richard (1862–1956) and Julius König (1849–1913), both in 1905.) Immediately appreciating the difficulty, Frege attempted to revise his work, adding an appendix to the *Grundgesetze* which discussed Russell's discovery. Nevertheless, he eventually felt forced to abandon his logicism. A projected third volume of the *Grundgesetze* which had been planned for geometry never appeared. Frege's later writings show that Russell's discovery had convinced him of the falsehood of logicism, and that he had opted instead for the view that all of mathematics, including number theory and analysis, was reducible only to geometry.

Despite his abandonment of logicism, it was Frege's dedication to truth which Russell commented upon in a letter many years later:

> As I think about acts of integrity and grace, I realize that there is nothing in my knowledge to compare with Frege's dedication to truth. His entire life's work was on the verge of completion, much of his work had been ignored to the benefit of men infinitely less capable,…and upon finding that his fundamental assumption was in error, he responded with intellectual pleasure clearly submerging any feelings of personal disappointment. It was almost superhuman and a telling indication of that which men are capable if their dedication is to creative work and knowledge instead of cruder efforts to dominate and be known.[9]

With the appearance of Russell's paradox, Hilbert's problem of proving consistency took on new urgency. After all, since (in classical logic) all sentences follow from a contradiction, no mathematical proof could be trusted once it was discovered that the underlying logic was contradictory. Important responses came not only from Hilbert and Russell, but from Brouwer and Zermelo as well.

The seeds of Hilbert's response were contained in his 1904 address to the Third International Congress of Mathematicians. In this address, Hilbert presented his first attempt at proving the consistency of arithmetic. (Earlier, in 1900, he had attempted an axiomatization of the

reals, R, and showed that the consistency of geometry depends upon the consistency of *R*.) Hilbert recognized that an attempt to avoid the contradictions by formalizing one's metalanguage would only lead to a vicious regress. As a result, he opted instead for an informal logic and metalanguage whose principles would be universally acceptable. His basic idea was to allow the use of only finite, well-defined and constructible objects, together with rules of inference which were deemed to be absolutely certain. Controversial principles such as the axiom of choice were to be explicitly excluded. The programme variously became known as the finitary method, formalism, proof theory, metamathematics and Hilbert's programme. Together with Wilhelm Ackermann (1896–1962), Hilbert went on to publish *Grundzüge der Theoretischen Logik (Principles of Mathematical Logic)* in 1928 and, together with Paul Bernays (1888–1977), the monumental two-volume work *Die Grundlagen der Mathematik (Foundations of Mathematics),* in 1934 and 1939, respectively. This latter work recorded the results of the formalist school up until 1938, including work done following the publication of Gödel's 1931 incompleteness theorems, after which it was concluded that the original finitistic methods of the programme had to be expanded.

Hilbert's finitary method had similarities to a second important response to the antinomies, that of Brouwer and the intuitionists. Like Hilbert, Brouwer held that one cannot assert the existence of a mathematical object unless one can also indicate how to go about constructing it. However, Brouwer argued, in addition, that the principles of formal logic were to be abstracted from purely mental mathematical intuitions. Thus, since logic finds its basis in mathematics, it could not itself serve as a foundation for mathematics. For similar reasons, Brouwer rejected the actual infinite, accepting only mathematical objects capable of effective construction by means of the natural numbers, together with methods of finite constructibility. On this view theoretical consistency would be guaranteed as a result of reformed mathematical practice.

Russell's own response to the paradox was contained in his aptly named theory of types. Russell's basic idea was that by ordering the sentences of a language or theory into a hierarchy (beginning with sentences about individuals at the lowest level, sentences about sets of individuals at the next lowest level, sentences about sets of sets of individuals at the next lowest level, etc.), one could avoid reference to sets such as the set of all sets, since there would be no level at which reference to such a set appears. It is then possible to refer to all things for which a given condition (or predicate) holds only if they are all at the same level or of the same 'type'. The theory itself admitted of two versions.

According to the simple theory of types, it is the universe of discourse (of the relevant language) which is to be viewed as forming a hierarchy. Within this hierarchy, individuals form the lowest type; sets of individuals form the next lowest type; sets of sets of individuals form the next lowest type; and so on. Individual variables are then indexed (using subscripts) to indicate the type of object over which they range, and the language's formation rules are restricted to allow only sentences such as '$a^n\ b^m$' (where $m=n+1$) to be counted among the (well-formed) formulas of the language. Such restrictions mean that strings such as '$x^n \in x^n$' are ill-formed, thereby blocking Russell's paradox.

The ramified theory of types goes further than the simple theory. It does so by describing a hierarchy, not only of objects, but of closed and open sentences (propositions and prepositional functions, respectively) as well. The theory then adds the condition that no proposition or prepositional function may contain quantifiers ranging over propositions or prepositional functions of any order except those lower than itself. Intuitively, this means that no proposition or prepositional function can refer to, or be about, any member of the hierarchy other than those which are defined in a logically prior manner. Since, for Russell, sets are to be understood as logical constructs based upon prepositional functions, it follows that the simple theory of types can be viewed as a special case of the ramified theory.

Russell first introduced his theory in 1903 in his *The Principles of Mathematics*. Later, in 1905, he abandoned the theory in order to consider three potential alternatives: the 'zigzag theory', in which only 'simple' propositional functions determine sets; the 'theory of limitation of size', in which the purported set of all entities is disallowed; and the 'no-classes theory', in which sets are outlawed, being replaced instead by sentences of certain kinds. Nevertheless, by 1908 Russell was to abandon all three of these suggestions in order to return to the theory of types, which he develops in detail in his article 'Mathematical Logic as Based on the Theory of Types'. The theory finds its mature expression in Whitehead and Russell's monumental work defending logicism, *Principia Mathematica*, the first volume of which appeared in 1910.

In order to justify both his simple and ramified theories, Russell introduced the principle that 'Whatever involves *all* of a collection must not [itself] be one of the collection'.[10] Following Henri Poincaré (1854–1912), Russell called this principle the 'Vicious Circle Principle' (or VCP). Once the VCP is accepted, it follows that the claim—first championed by Peano and later by Frank Ramsey (1903–30)—that there is an important theoretical distinction between the set-theoretic and the semantic paradoxes, is mistaken. The reason is that in both

cases the VCP provides a philosophical justification for outlawing self-reference.

Yet a fourth response to the paradoxes was Zermelo's axiomatization of set theory. In 1904 Zermelo had solved one of Hilbert's twenty-three problems of the 1900 Congress by proving that every set can be well ordered. Four years later, in 1908, he developed the first standard axiomatization, Z, of set theory, improving upon both Dedekind's and Cantor's original, more fragmentary treatments.

Zermelo's axioms were designed to resolve Russell's paradox by restricting Cantor's naive principle of abstraction—the principle that from each and every predicate expression a set could be formed. Specifically, Zermelo's axiom of replacement would disallow the construction of paradoxical sets (such as the set of all sets that are not members of themselves), but would still allow the construction of other sets necessary for the development of mathematics. *ZF,* the axiomatization generally used today, is a modification of Zermelo's theory developed primarily by Abraham Fraenkel (1891–1965). When *ZF* is supplemented by the axiom of choice (proved independent by Fraenkel in 1922), the resulting theory, *ZFC,* may be summarized as follows:

1 Axiom of Extensionality:
$$(\forall x)(x \in A \longleftrightarrow x \in B) \rightarrow A = B$$

2 Sum Axiom:
$$(\exists C)(\forall x)(x \in C \longleftrightarrow (\exists B)(x \in B \,\&\, B \in A))$$

3 Power Set Axiom:
$$\exists B)(\forall C)(C \in B \longleftrightarrow A \supseteq C)$$

4 Axiom of Regularity:
$$(A \neq o \rightarrow (\exists x)(x \in A \& (\forall y)(y \in x \rightarrow y \notin A))$$

5 Axiom of Infinity:
$$(\exists A)(o \in A \& (\forall B)(B \in A \rightarrow B \cup \{B\} \in A))$$

6 Axiom Schema of Replacement:
If $(\forall x)(\forall y)(\forall z)(x \in A \& \phi(x,y) \,\&\, \phi(x,z) \rightarrow y = z)$
then $(\exists B)(\forall y)(y \in B \longleftrightarrow (\exists x)(x \in A \,\&\, \phi(x,y)))$

7 Axiom of Choice:
For any set *A* there is a function, *f*, such that
for any non-empty subset, *B*, of *A*, $f(B) \in B$.

As a result of the work of many others, including Thoralf Skolem (1887–1963), Leopold Löwenheim (1878–1957), and John von Neumann (1903–57), it is recognized that many additional axioms variously used to formalize set theory may be derived from the above list of axioms. For example, the separation axioms are derivable from the axiom schema of replacement; the pairing axiom is derivable from the power set axiom together with the

axiom schema of replacement; and the union axiom is derivable from the axiom of extensionality, the sum axiom and the pairing axiom. (Other axioms, such as an axiom for cardinals, that $\mathcal{K}(A)=\mathcal{K}(B)\leftrightarrow A\approx B$, are also occasionally added to the above list to form extensions of *ZFC*.)

Overall, these four responses to the antinomies signalled the arrival of a new and explicit awareness of the nature of formal systems and of the kinds of metalogical results which are today commonly associated with them. Specifically, formal systems are typically said to comprise:

1 a set of primitive symbols, which form the basic vocabulary of the system;
2 a set of formation rules, which provide the basic grammar of the system and which determine how primitive symbols may be combined to form well-formed formulas (sentences) of the system;
3 a set of axioms, which articulate any fundamental assumptions of the system; and
4 a set of transformation rules (or rules of inference), which provide the mechanism for proving formulas of the system called theorems.

Together, 1 and 2 are said to constitute the formal language of the system, 3 and 4 the logic of the system, and 1–4 the primitive basis of the system as a whole. A formal system thus consists essentially of an explicit, effective mechanism for the selection of a well-defined subset of well-formed formulas, known as the theorems of the system. Such systems may be either axiomatic or natural deduction systems, depending upon whether they emphasize the use of axioms at the expense of rules of inference, or rules of inference at the expense of axioms. In either case, each theorem is proved through a finite sequence of steps, each of which is either the statement of an axiom, or is justified (possibly from earlier formulas) by the allowed rules of inference.

Each formal system may be viewed from the point of view of proof theory (i.e. from the point of view of the system's syntax alone), but, following Tarski, it may also be viewed from the point of view of model theory (i.e. from the point of view of an interpretation, in which meanings are assigned to the formal symbols of the system). Given a set, *S*, of well-formed formulas, an interpretation consists of a non-empty set (or domain), together with a function which:

1 assigns to each individual constant found in members of *S* an element of the domain;
2 assigns to each *n*-place predicate found in members of *S* an *n*-place relation between members of the domain;
3 assigns to each *n*-place function-name found in members of *S* a

function whose arguments are *n*-tuples of elements of the domain and whose values are also elements of the domain; and

4 assigns to each sentence letter a truth value.

Logical constants, such as those representing truth functions and quantifiers, are assigned standard meanings using rules (such as truth tables) which specify how well-formed formulas containing them are to be evaluated. Any interpretation that satisfies the axioms of the system is called a model.

Among the most influential of formal systems to be developed were of course those associated with Frege's propositional and predicate logics. Propositional (or sentential) logic may thus be defined as a formal system or logical calculus which analyses truth-functional relations between propositions (sentences or statements). Any such system is based upon a set of propositional (sentential or statement) constants and connectives (or operators) which are combined in various ways to produce propositions of greater complexity. Standard connectives include those representing negation (~), conjunction (&), (inclusive) disjunction (∨), material implication (→), and material equivalence (↔). A standard axiomatization consists of several definitions (including the definitions that $p \rightarrow q =^{df} \sim p \vee q$, that $p \& q =^{df} \sim(\sim p \vee \sim q)$, and that $p \leftrightarrow q =^{df} (p \rightarrow q) \ \& \ (q \rightarrow p))$, the rules of substitution and detachment, and the following axioms:

1 $(p \vee p) \rightarrow p$
2 $q \rightarrow (p \vee q)$
3 $(p \vee q) \rightarrow (q \vee p)$
4 $(q \rightarrow r) \rightarrow ((p \vee q) \rightarrow (p \vee r))$.

Similarly, Hilbert's positive propositional calculus (which contains all and only those theorems of the classical calculus which are independent of negation), Heyting's intuitionistic propositional calculus (which uses intuitionistic, rather than classical, negation), the several systems of modal logic introduced by C.I.Lewis (1883–1964), and many-valued logics, such as those introduced by Jan Łukasiewicz (1878–1956), are all examples of propositional logics. (As Łukasiewicz also pointed out, logics such as the standard propositional calculus may be reformulated, using so-called Polish notation, in such a way as to avoid the need for scope indicators such as parentheses; thus, letting *N* represent negation, *K* represent conjunction, *A* represent disjunction (or alternation), *R* represent exclusive disjunction, *C* represent material implication, *E* represent material equivalence, *L* represent necessity, and *M* represent possibility, sentences such as $\sim(p \rightarrow (p \ \& \ q))$ and $\Box(p \rightarrow p)$ may be represented as *NCpKpq* and *LCpp*, respectively.)

Like propositional logic, predicate logic may also be defined as a

formal system or logical calculus, but one which analyses the relations between individuals and predicates within propositions, in addition to the truth-functional relations between propositions which are analysed within propositional logic. Each such system is based upon a set of individual and predicate (or functional) constants, individual (and sometime predicate) variables, and quantifiers (such as $\exists$ and $\forall$) which range over (some of) these variables, in addition to the standard constants and connectives of the propositional calculus. A standard axiomatization of first-order predicate logic can thus be viewed as an extension of the propositional calculus. One such axiomatization consists of the formulas and inference rules of the propositional calculus, together with the rule of universal generalization (that if A is a theorem, so is $(\forall a)A$) and the following axiom schemata:

1 If A is a uniform substitution instance of a valid well-formed formula of propositional logic (i.e. a formula obtained from a valid formula of propositional logic by uniformly replacing every variable in it by some well-formed formula of the first-order predicate calculus), then A is an axiom;
2 If a is an individual variable, A any well-formed formula, and B any well-formed formula differing from A only in having some individual variable b replacing every free occurrence of a in A, then $(\forall a)A \rightarrow B$ is an axiom, provided that a does not occur within the scope of any occurrence of a quantifier containing b;
3 $(\forall a)(A \rightarrow B) \rightarrow (A \rightarrow (\forall a)B)$, provided a is not free in A.

Other predicate logics include second-order logic (also called the second-order predicate or functional calculus), higher-order logics, in which quantifiers and functions range over predicate (or functional) variables and/or constants of the system, and modal (and other) extensions of both first- and higher-order logics. When the set of individual or predicate constants is empty, a predicate calculus is said to be pure; otherwise it is said to be applied.

With propositional and predicate logic formalized, the systematic metalogical study of formal properties of logical systems, and the investigation of informal, philosophical problems resulting from such results, began to develop. Among the most important metalogical results to be proved at the level of propositional logic are the completeness and soundness results (which show, respectively, that all valid formulas are theorems of the system and that all theorems of the system are valid formulas), the deduction theorem (which states that, if there is a proof from 's_1, s_2,…, sn' to 's_{n+1}', then there is also a proof from 's_1, s_2,…, s_{n-1}' to 'if s_n then s_{n+1}'), and the decidability result (which shows that there is an effective, mechanical decision procedure—such as truth tables—for determining the validity of any arbitrary formula of the system).

Among the metatheorems proved for first-order logic are similar completeness and soundness results, Tarski's theorem concerning the undefinability of (arithmetical) truth, and the now famous Löwenheim-Skolem theorems. These are a family of metatheoretical results proved by Löwenheim in 1915, and extended by Skolem in 1920 and 1922, to the effect that if there is an interpretation in which an enumerable set of sentences is satisfiable in an enumerably infinite domain then the set is also satisfiable in every infinite domain and, similarly, that if there is an interpretation in which a set of sentences is satisfiable in a non-empty domain then it is also satisfiable in an enumerably infinite domain. This latter theorem gives rise to the so-called 'Skolem's paradox', the unintuitive (but ultimately non-contradictory) result that systems for which Cantor's theorem is provable, and hence which must contain non-denumerable sets, nevertheless must be satisfiable in a (smaller) enumerably infinite domain.

Despite such impressive results, Hilbert's goal of discovering a consistency proof for arithmetic remained elusive. The explanation came with a paper published by Gödel in 1931. Today Gödel is remembered for several important results, any one of which would have given him a position of importance in the history of logic. Most famously, these included his proofs of the completeness and compactness of first-order logic in 1930, and the incompleteness of arithmetic in 1931. They also include results in constructive logic in 1932 and computation theory in 1933, as well as his 1938 proof that the continuum hypothesis is consistent with the Zermelo-Fraenkel axioms of set theory—in other words, that the usual axioms of set theory could never prove the continuum hypothesis false. (That the negation of the continuum hypothesis is also consistent with the Zermelo-Fraenkel axioms of set theory, and hence that the hypothesis is independent of the standard axiomatization for set theory, was proved twenty-five years later by Paul Cohen (b. 1934).)

Of these results, several require further comment. It was in Gödel's 1930 doctoral dissertation at the University of Vienna that the completeness of the first-order predicate calculus was proved for the first time. Completeness is the property that every valid formula of the system is provable within the system. This turns out to be equivalent to the claim that every formula is either refutable or satisfiable. Building on the results of Löwenheim and Skolem, Gödel succeeded in proving a result slightly stronger than this, a result which also entails the Löwenheim-Skolem theorem. Gödel then generalized his result to first-order logic with identity and to infinite sets of formulas. At the same time Gödel proved the compactness theorem for first-order logic, which states that any collection of well-formed formulas of a given

language has a model if every finite subset of the collection has a model.

Equally famous, however, are Gödel's two theorems relating to the incompleteness of systems of elementary number theory. The first of these two theorems states that any ω-consistent system adequate for expressing elementary number theory is incomplete, in the sense that there is a valid well-formed formula of the system that is not provable within the system. (A formal system is ω-consistent if whenever it has as theorems that a given property, *P,* holds of all individual natural numbers, then it fails to have as a theorem that *P* fails to hold of all numbers.) In 1936 this theorem was extended by J.B.Rosser (b. 1907) to apply, not just to any ω-consistent system, but to any consistent system of the relevant sort. The second theorem states that no consistent system adequate for expressing elementary number theory may contain a proof of a sentence known to state the system's consistency. Hence, the difficulty in resolving Hilbert's second problem.

Received by the publisher on 17 November 1930 but published the following year, Gödel's theorems were proved in what is, together with *Principia Mathematica,* one of the two most famous logical works of the current century: 'Über Formal Unentscheidbare Sätze der *Principia Mathematica* und Verwandter Systeme I' ('On Formally Undecidable Propositions of *Principia Mathematica* and Related Systems I'). The system Gödel uses is equivalent to the logic of Whitehead and Russell's *Principia Mathematica* without the ramified theory of types but supplemented by the arithmetical axioms of Peano. (A corollary shows that even supplemented by the axiom of choice or the continuum hypothesis, the system still contains undecidable propositions.)

By introducing his famous system of 'Gödel numbering', Gödel assigns natural numbers to sequences of signs and sequences of sequences of signs within the system. This is done in such a way that, given any sequence, the number assigned to it can be effectively calculated, and given any number, it can be effectively determined whether a sequence is assigned to it and, if so, what it is. Metamathematical predicates used to describe the system in this way can be correlated with number-theoretic predicates. For example, the metamathematical notion of being an axiom can be expressed using the predicate *Ax(x),* which in turn corresponds to exactly those Gödel numbers, *x,* which are correlated to the axioms of the system. Referring to the set of axioms can then be accomplished simply by referring to this set of Gödel numbers.

Theorem VI of Gödel's 1931 paper states that in a formal system of the specified kind there exists an undecidable proposition (that is, a proposition such that neither it nor its negation is provable within the

system). It is this theorem which is commonly referred to as Gödel's first incompleteness theorem (G1). In addition to proving G1, Gödel also proves several other corollaries: for example, that among the propositions whose validity is undecidable are both arithmetic propositions (Theorem VIII) and formulas of pure first-order logic (Theorem IX), and that a statement which expresses the consistency of the system and which can be written as a formula in the system is itself among those formulas not provable in the system (Theorem XI). It is this last theorem, Theorem XI, which is commonly referred to as Gödel's second incompleteness theorem (G2). Both of Gödel's incompleteness theorems required that logicians and mathematicians view formal systems of arithmetic in a new light.

FROM GÖDEL TO FRIEDMAN

Hilbert's programme in effect had two main goals concerning the foundations of mathematics. The first was descriptive, the second justificatory. The descriptive goal was to be achieved by means of the complete formalization of mathematics. The justificatory goal was to be achieved by means of a finitary (and hence epistemologically acceptable) proof of the reliability of those essential but non-finitary (and hence epistemologically more suspect) parts of mathematics. Work by both formalists and logicists during the first two decades of the century had effectively accomplished the former of these two goals. Ideally a finitary consistency proof would accomplish the latter.

Gödel's second incompleteness theorem, G2, is often thought relevant to Hilbert's programme for just this reason. Specifically, it is often claimed that G2 implies three philosophically significant corollaries: first, that any consistency proof for a theory, *T*, of which G2 holds will have to rely upon methods logically more powerful than those of theory *T* itself; second, that (in any significant case) a consistency proof for theory *T* can yield no epistemological gain and so cannot provide a satisfactory answer to the sceptic regarding *T*'s consistency; and third, that as a result of this, G2, if not strictly implying the outright failure of Hilbert's programme, at the very least indicates that significant modifications to it are needed. All three of these 'corollaries' are controversial.[11] In fact, Gödel himself explicitly makes the point that the truth of G2 should not be viewed, by itself, as sufficient reason for abandoning Hilbert's goal of discovering a finitary consistency proof:

> I wish to note expressly that Theorem XI (and the corresponding results for *M* and *A*) do not contradict Hilbert's formalistic viewpoint. For this viewpoint presupposes only the existence of a

> consistency proof in which nothing but finitary means of proof is used, and it is conceivable that there exist finitary proofs that *cannot* be expressed in the formalism of *P* (or of *M* or *A*).[12]

Nevertheless, the formalists themselves drew the moral that radical changes to their programme were required; thus, the 1936 consistency proof by Gerhard Gentzen (1909–45) required the use of transfinite induction up to the ordinal ε_0.

Other consequences also followed. Among them was a renewed interest in the problem of decidability, the problem of finding an effective, finite, mechanical, decision procedure (or algorithm) for determining whether an arbitrary, well-formed formula of a system is in fact a theorem of the system. A positive solution to such a problem is a proof that an effective procedure exists. A negative solution is a proof that an effective procedure does not exist. By 1931 it was already well known that a positive solution existed in the case of prepositional logic, that a decision procedure existed in the form of truth tables for determining whether an arbitrary formula was a tautology. However, in 1936 Church proved that there could be no such decision procedure for validity (or equivalently, for semantic entailment) in first-order logic.

Church proved that there does exist a decision procedure for determining that valid first-order sentences are valid. However, at the same time he also proved that there is no corresponding procedure for showing of sentences which are not valid that they are not valid. In other words, although there is an effective, finite, mechanical, positive test for first-order validity, there is, and can be, no such negative test. Thus, given an arbitrary first-order sentence, there can be no effective, finite, mechanical decision procedure for determining whether or not it is valid.

Central to Church's theorem was the idea of computability. Intuitively, a computable function may be said to be any function for which there exists an effective decision procedure or algorithm for calculating a solution. Several suggestions were offered as a means of making this notion more precise, not only by Gödel and Church, but by Emil Post (1897–1954) and Alan Turing (1912–54) as well. One such precise suggestion was to identify effective computability with that given by a Turing machine; another was to identify it with a series of functions identifiable in the lambda calculus; yet a third was to identify it with that of a general recursive function. Perhaps surprisingly, all three notions turned out to be equivalent. As a result, the thesis of identifying computability with the mathematically precise notion of general recursiveness became known alternatively as Church's thesis or the Church-Turing thesis.

Intuitively, a Turing machine can be thought of as a computer which

manipulates information contained on a linear tape (which is infinite in both directions) according to a series of instructions. More formally, the machine can be thought of as a set of ordered quintuples, $\langle q_i, S_i, S_j, I_i, q_j \rangle$, where q_i is the current state of the machine, S_i is the symbol currently being read on the tape, S_j is the symbol with which the machine replaces S_i, I_i is an instruction to move the tape one unit to the right, to the left, or to remain where it is, and q_j is the machine's next state. From this rather impoverished set of operations it turns out that a wide range of functions are computable. It also turns out that the decision problem for first-order validity is capable of being modelled via Turing machines since, by assigning unique numbers to first-order sentences, there will be a function which returns 1 if given a number representing a valid sentence and 0 otherwise. The question of whether this function is finitely and mechanically calculable turns out to be equivalent to the so-called halting problem, the problem of discovering an effective procedure for determining whether the appropriate Turing machine will ever halt, given arbitrary input. Church's theorem is equivalent to the result that such a function is not finitely and mechanically calculable.

Equivalent classes of functions turned out to be identifiable in the lambda calculus and in recursion theory. The former gains its name from the notation used to name functions. Terms such as *'f(x)'* or the 'successor of *y*' are used to refer to objects obtained from *x* or *y* by the appropriate functions. To refer to the functions themselves, Church introduced a notation which yields, respectively, **'$(\lambda x)(f(x))$'** and *'*(λy) (successor of *y*)' Having done so, he then identified a class of functions which turned out to be identical to both the Turing computable functions and the recursive functions.

The latter may be defined as a set of functions whose members are said to be either primitive recursive or general recursive, and which are themselves constructed from a set of more fundamental functions by a series of fixed procedures.

Specifically, a *constant* function is a function that yields the same value for all arguments. A *successor* function is a function that yields as its value the successor of its argument, for example, $s(1)=2$, $s(35)=36$. An *identity* function of *n* arguments is a function that yields as its value the *i*th of its *n* arguments. Together, the constant, successor and identity functions are called the *fundamental* functions.

In addition, given a set of functions h_i, each, of *n* arguments, a new function, *f*, of *n* arguments is defined by *composition* such that the value of the new function is equal to the value of a previously introduced function, *g*, whose arguments are the values of each of the members of the original set of functions when their arguments are the arguments of the newly introduced function. In other words, if *f* is being defined by composition

and g, $h_1,\ldots h_m$ are previously defined functions, then $f(x_1,\ldots,x_n)=g(h_1(x_1,\ldots,x_n),\ldots, h_m(x_1,\ldots, x_n))$.

Similarly, a new function, f, of n arguments is defined by *primitive recursion* as follows: first, if a designated argument is 0, then f is defined in terms of a previously defined function, g, of n-1 arguments whose arguments are taken to be exactly those of f except for the designated argument, 0. In other words, if f is being defined by recursion and g is a previously defined function, then $f(x_1,\ldots,x_{n-1},0)=g(x_1,\ldots, x_n)$. Second, if the designated argument is not 0, and is instead the successor, c+1, of some number, c, then f is defined in terms of a previously defined function, g, of n+1 arguments whose arguments are taken to be exactly those of f except for the designated argument, c+1, together with c and the value of f when its arguments are exactly those arguments already given for g. In other words, if f is being defined by recursion and g is a previously defined function, then $f(x_1,\ldots,x_{n-1}, c+1)= g(x_1,\ldots, x_{n-1}, c, f(x,\ldots,x_{n-1},c))$.

Any function which is either a fundamental function or can be obtained from the fundamental functions by a finite number of applications of composition and primitive recursion is then said to be a *primitive recursive* function.

Next, a new function, f of n arguments is defined by *minimization* such that its value (whenever it exists) is the least c such that, given a previously defined function, g, whose arguments are exactly the arguments of f together with c, g has the value 0. If there is no such c, then f remains undefined for those arguments. In other words, if f is being defined by minimization and g is a previously defined function, then $f(x_1,\ldots, x_n)$=the least c such that $g(x_1,\ldots,x_n, c)=0$, provided that there exists some c; otherwise f is undefined.

Any function which is either a fundamental function or can be obtained from the fundamental functions by a finite number of applications of composition, primitive recursion, and minimization is then said to be a *general recursive* (or simply *recursive*) function.

Examples of recursive functions include familiar arithmetical operations such as addition, multiplication, and others. Thus, letting z refer to the zero function (a constant function which yields the value zero), s the successor function, id^n_i an identity function of n arguments which yields its i^{th} argument as its value, Cn composition, and Pr primitive recursion, such functions can be defined as follows:

1 for sum, where $sum(x, y)=x+y$, we let
$sum = Pr[id, Cn[s, id^3_3]]$
or, more intuitively, $x+0=x$ and $x+s(y)=s(x+y)$
2 for product, where $prod(x, y)=x.y$, we let
$prod = Pr[z, Cn[sum, id^3_1, id^3_3]]$

or, more intuitively, $x.0=0$ and $x.s(y)=x+(x.y)$

3 for exponentiation, where $exp(x, y)=x^y$, we let

$$\boldsymbol{exp = Pr[Cn[s, z], Cn[prod, id^3_1, id^3_3]]}$$

or, more intuitively, $x^0=1$ and $x^{s(y)}=x.x^y$

4 for factorial, where $fac(y)=y!$, we let

$$\boldsymbol{fac = Pr[s(o), Cn[prod, Cn[s, id^2_1], id^2_2]]}$$

or, more intuitively, $0!=1$ and $s(y)!=s(y).y!$.

The proved identification of the class of recursive functions with the other two classes of functions thought to express the intuitive concept of computability lent strong support to the Church-Turing thesis.

Having observed both the incompleteness of first-order theories of arithmetic and the undecidability of first-order validity, questions naturally turned to other issues relating to computability. One such issue is that of computational complexity. Another concerns the extent and nature of arithmetical incompleteness. Recently, advances have been made in both of these areas.

The computational complexity of a problem is a measure of the computational resources required to solve the problem. In this context, the distinction is made between problems solvable by polynomial-time algorithms and problems which, if solvable, have solutions which are testable in polynomial time but which, if not solvable, do not. Problems of the former kind are said to be members of the class of problems P, while problems of the latter kind are members of the class NP. Those problems in NP which are measurably the hardest to solve are said to be NP-complete. Today the problem of whether P=NP remains open. Nevertheless, in 1971 Stephen Cook (b. 1939) proved that the problem of satisfiability (the problem of determining, given an arbitrary set of sentences, whether it is possible for all of the sentences to be jointly true) is at least as difficult to solve as is any NP-complete problem [1.87]. The result is important since it unifies the class of NP-complete problems in a way that was unappreciated prior to 1971.

Similarly, advances have been made concerning the extent and nature of arithmetical incompleteness. Chief among these are the 1981 independence results of Harvey Friedman (b. 1948) [1.58]. Friedman's contributions include the discovery of a series of mathematically natural propositions (concerning Borel functions of several variables) that are undecidable, not just in *ZFC,* but in the much stronger system of *ZFC* together with the axiom of constructibility, *V=L,* as well. This is important not simply because such propositions are of a level of abstraction significantly lower than previous results, but because virtually all propositions previously thought to have been undecidable have been made decidable by the addition of the axiom of constructibility to *ZFC*.

Importantly, Friedman has also shown that some of these propositions, although undecidable in *ZFC*, are decidable in a competing theory, Morse-Kelly class theory with choice. Such results are important since they indicate in what ways competing axiomatizations of set theory in fact differ.

THE EXPANSION OF LOGIC

As long ago as Galen (*c.* 129–*c.* 199) it was recognized that some sound arguments could not adequately be analysed in terms of either Aristotelian or Stoic logic. For example, neither the argument 'if Sophroniscus is father to Socrates, then Socrates is son to Sophroniscus', nor the argument 'if Theon has twice as much as Dio, and Philo twice as much as Theon, then Philo has four times as much as Dio' is provably valid in such systems.[13] Thus, modern first-order logic can be viewed as a means of extending the ancient idea of formal validity, since it successfully displays many formally valid inferences which ancient logic fails to capture.

One way of understanding the advent of contemporary nonclassical and informal logics is to view them in much the same way. Such logics regularly attempt to describe, in a systematic way, additional types of reliable inference not captured in classical first-order logic. They do so in two ways: first, *extensions* of classical logic attempt to exhibit reliable forms of inference in addition to those displayed in first-order logic much as first-order logic exhibits reliable forms of inference in addition to those displayed in ancient logic or in modern propositional logic. Second, *competitors* to classical logic advocate alternative ways of understanding the idea of valid inference itself, rejecting in one way or another the concept of validity as it is described in first-order logic.

Among the most philosophically interesting of the competitors to classical logic are intuitionistic logics, relevance logics and paraconsistent logics. Of these, intuitionistic logics were the first to appear. Motivated by the intuitionistic idea that satisfactory proofs must refer only to entities which can be successfully constructed or discovered, intuitionist logic requires that we find examples, or that we find algorithms for finding examples, of each object or set of objects referred to in a proof. Formalized by Heyting, intuitionistic logic therefore abandons those forms of classical proof (including indirect proof) which do not contain the appropriate constructions. A standard axiomatization consists of rules for substitution and detachment, together with the following axioms:

1 $p\rightarrow(p\wedge p)$
2 $(p\wedge q)\rightarrow(q\wedge p)$
3 $(p\rightarrow q)\rightarrow((p\wedge r)\rightarrow(q\wedge r))$
4 $((p\rightarrow q)\wedge(q\rightarrow r))\rightarrow(p\rightarrow r)$
6 $(p\wedge(p\rightarrow q))\rightarrow q$
7 $p\rightarrow(p\vee q)$
8 $(p\vee q)\rightarrow(q\vee p)$
9 $((p\rightarrow r)\wedge(q\rightarrow r))\rightarrow((p\vee q)\rightarrow r)$
10 $\neg p\rightarrow(p\rightarrow q)$
11 $((p\rightarrow q)\wedge(p\rightarrow\neg q))\rightarrow\neg p$.

It follows in Heyting's logic that the sentence '$p\vee\neg p$' is not a theorem and that inferences, such as those from '$\neg\neg p$' to 'p' and from '$\neg(\forall x)Fx$' to '$(\exists x)\neg Fx$', are not allowed.

Like intuitionistic logic, relevance logic is a competitor to classical logic which emphasizes a non-classical consequence relation. Like intuitionistic logic, too, relevance logic results from a dissatisfaction with the classical consequence relation. Developed by Alan Ross Anderson (1925–73), Nuel Belnap (b. 1930) and others, the logic stresses entailments which involve connections of relevance between premisses and conclusions, rather than simple classical derivability conditions. It is intended that the relevance consequence relation thereby avoids both the paradoxes of material implication and the paradoxes of strict implication. (The former involve the unintuitive but, strictly speaking, non-contradictory results to the effect that whenever the antecedent is false or the consequent is true in a material implication, the resulting implication will be true, regardless of content; the latter involve the unintuitive, but likewise non-contradictory, results that a necessary proposition is strictly implied by any proposition and that an impossible proposition strictly implies all propositions, regardless of content. Following Lewis's 1912 definition, one sentence, p, is said to strictly imply a second sentence, q, if and only if it is not possible that both p and $\sim q$.)

As it is normally formalized, relevance logic turns out to be a type of paraconsistent logic. Such logics tolerate, but do not encourage, inconsistencies. They do so in the sense that a contradiction (the joint assertion of a proposition and its denial) may be contained within the system; at the same time they are consistent in the sense that not every well-formed formula is a theorem. One example of such a logic (as in [1.146]), which is not a relevance logic, may be outlined as follows: Let $M=\langle W, R, w^*, v\rangle$ be a semantic interpretation of a formal system, with W an index set of possible worlds, w_i, R a binary relation on W, w* the actual world, and v a valuation of the propositional constants, i.e. a map from W×P (with P the set of propositional constants) into {{1}, {0}, {1, 0}}, the set

of truth values. (More naturally, we write $v(w, \alpha) = x$ as $v_w(\alpha)=x$ and read '$1 \in v_w(\alpha)$' as 'α is true under v at w' and '$0 \in v_w(\alpha)$' as 'α is false under v at w'.) Valuation v can then be extended to all well-formed formulas as follows:

$\neg$ $1 \in v_w(\neg\alpha)$ iff $0 \in v_w(\alpha)$
$0 \in v_w(\neg\alpha)$ iff $1 \in v_w(\alpha)$

$\wedge$ $1 \in v_w(\alpha \wedge \beta)$ iff $1 \in v_w(\alpha)$ and $1 \in v_w(\beta)$
$0 \in v_w(\alpha \wedge \beta)$ iff $0 \in v_w(\alpha)$ or $0 \in v_w(\beta)$

$\vee$ $1 \in v_w(\alpha \vee \beta)$ iff $1 \in v_w(\alpha)$ or $1 \in v_w(\beta)$
$0 \in v_w(\alpha \vee \beta)$ iff $0 \in v_w(\alpha)$ and $0 \in v_w(\beta)$

$\rightarrow$ $1 \in v_w(\alpha \rightarrow \beta)$ iff for all w_i such that w_iRw,
if $1 \in v_{w_i}(\alpha)$ then $1 \in v_{w_i}(\beta)$, and
if $0 \in v_{w_i}(\beta)$ then $0 \in v_{w_i}(\alpha)$
$0 \in v_w(\alpha \rightarrow \beta)$ iff for some w_i such that w_iRw,
$1 \in v_{w_i}(\alpha)$ and $0 \in v_{w_i}(\beta)$.

Definitions of semantic consequence and logical truth are then introduced in the standard way:

$\Sigma \models \alpha$ iff for all interpretations, *M*, it is true of the evaluation, *v*, that
if $1 \in v(\beta)$ for all $\beta \in \Sigma$, then $1 \in v(\alpha)$
$\models \alpha$ iff for all interpretations, *M*, itis true of the evaluation, *v*, that
$1 \in v(\alpha)$.

Given these semantics, some rules of inference, such as disjunctive syllogism ($P \vee Q$, $\neg P + Q$), fail. As a result, the logic turns out to be paraconsistent in just the sense outlined above.

Other competing logics include combinatory logic (a variable-free branch of logic which contains functions capable of playing the role of variables in ordinary logic); free logics (logics in which it is not assumed that names successfully refer, hence logics which do not make the kind of existence assumptions normally associated with classical logic); many-valued logics (logics which countenance more than the two possible classical truth values, truth and falsity; historically, such logics have been motivated by the problem of future contingents, the problem first raised by Aristotle but popularized by Lukasiewicz of determining whether contingent statements concerning future states have truth values prior to the time to which they refer); and quantum logics (logics designed to take account of the unusual entailment relations between propositions in theories of contemporary quantum physics; hence, a logic in which the law of distributivity fails).

In contrast to the above logics, extensions of first-order logic typically have as their goal the construction of a broader, more inclusive type of consequence relation than that found in classical logic. Formal extensions, such as modal extensions of both prepositional and predicate logic, do so by expanding the concept of formal entailment to include a class of formally valid arguments in addition to those of first-order logic. In contrast, informal extensions do so by expanding the concept of validity to include informal (or material) validity in addition to formal validity. Finally, inductive or non-monotonic extensions do so by expanding the concept of consequence to include, not just entailments, but implications, corroborations, and confirmations as well. Thus it is that logic (in the broad sense) has come to include, not just theories of formal entailment relations, but probability theory, confirmation theory, decision theory, game theory and theories of epistemic modelling as well.

Among the most important extensions to classical logic are the modal extensions. These are extensions emphasizing inferential relations resulting from the alethic modalities, including necessity, possibility, impossibility and contingency. Such logics are obtained from classical prepositional or predicate logic by the addition of axioms and rules of inference governing operators such as $\Box$ and $\Diamond$ in '$\Box\ p$' ('it is necessary that p') and '$\Diamond p$' ('it is possible that p'). The weakest logic generally thought to count as a modal logic in this sense is a logic introduced by Robert Feys (b. 1889) in 1937, system *T*. A standard axiomatization consists of the axioms and rules of inference for classical propositional logic, together with several definitions (including the definition that $\Diamond p =_{df} {\sim}\Box{\sim} p$), the rule of necessitation (to the effect that if p is a theorem, so is $\Box\ p$), and the following axioms:

1 $\Box\ p \rightarrow p$
2 $\Box\ (p \rightarrow q) \rightarrow (\Box\ p \rightarrow \Box q)$.

Additional modal systems, including the 1932 systems *S*1 to *S*5, introduced by Lewis and C.H.Langford (1895–1964), are normally developed as extensions of *T*[1.37]. Since a formula, p, is said to strictly imply another formula, q, if and only if it is not possible that both p and ${\sim}q$, modal logics may be viewed either extensionally as a type of many-valued logic or intensionally as a theory of strict implication. The standard possible world semantics for such logics (in which a proposition is necessary if and only if it is true in all possible worlds, impossible if and only if it is true in no possible world, possible if and only if it is true in at least one possible world, and so on) was developed by Saul Kripke (b. 1940).

Like modal logics, epistemic logics (logics emphasizing inferential relations and entailments which result from epistemic properties of

sentences) may be obtained from classical prepositional or predicate logic by the addition of axioms and rules of inference governing operators such as *K* and *B* in *'Kp'* ('it is known that *p*') and *'Bp'* ('it is believed that *p*'). Similarly, deontic logics (logics emphasizing inferential relations and entailments which result from deontic properties of sentences) may be obtained by the addition of axioms and rules of inference governing operators such as *O* and *P* in *'Op'* ('it ought to be the case that *p*') and *'Pp'* ('it is permissible that *p*').

Other extensions include counterfactual logics (logics which are primarily concerned with conditional sentences containing false antecedents); erotetic or interrogative logics (logics emphasizing inferential relations and entailments pertaining to questions and answers); fuzzy logics (logics concerned with imprecise information, such as information conveyed through vague predicates or information associated with so-called fuzzy sets, sets in which membership is a matter of degree); imperative logics (logics emphasizing inferential relations and entailments which result from imperatives); mereology (the formal study of inferences and entailments which result from the relationship of whole and part); theories of multigrade connectives (logics whose connectives fail to take a fixed number of arguments); plurality, pleonotetic or plurative logics (logics emphasizing inferential relations and entailments pertaining to relations of quantity and involving plurality quantifiers such as 'most' and 'few'); preference logics (logics emphasizing inferential relations and entailments which result from preferences); second-order and higher-order logics (logics carried out in higher-order languages in which quantifiers and functions are allowed to range over properties and functions as well as over individual i.e. individuals); and tense or temporal logics (logics designed to be sensitive to the tense of sentences and to the changing truth values of sentences over time).

In contrast to the above logics, informal logic is the study of arguments whose validity (or inductive strength) depends upon the material content, rather than the form or structure, of their component statements or propositions. (The logical form of a sentence or argument is obtained by making explicit the expression's logical constants and then by substituting free variables for its non-logical constants; logical form is thus typically contrasted with the material content—or subject matter—of the non-logical constants for which the free variables are substituted.) Such logics are extensions of formal logic in that they recognize the significance of formal validity, but also recognize the existence of valid arguments which are not instances of valid argument forms. Thus the argument from 'If Hume is a male parent then Hume is a father' and 'Hume is a father' to 'Hume is a male parent', although valid, is not formally so. In fact, far from being formally valid, it is an instance of the invalid argument form of affirming the consequent. Since all so-called invalid argument forms have

valid arguments as uniform substitution instances, the claim is made that formal characterizations alone will never be able to capture completely the concepts of either validity or invalidity.

Finally, mention should be made of formal systems which expand the traditional consequence relation by weakening it to a relation which is less than that of a valid inference. Such systems include inductive and non-monotonic logics, as well as theories of probability and confirmation. All such systems are concerned with so-called ampliative arguments, arguments whose conclusions in some important sense go beyond the information contained in their premisses. Such arguments are defeasible in the sense that their premisses fail to provide conclusive evidence for their conclusions and, hence, allow for the later overturning or revision of a conclusion. Ampliative arguments include both inductive inferences and inferences to the best explanation. They may be either acceptable or unacceptable depending upon their (inductive or probabilistic) strength or weakness. Similarly, confirmation theories evaluate the degree to which evidence supports (or confirms) a given hypothesis, emphasizing the rational degree of confidence that a cognitive agent should have in favour of a hypothesis given some body of evidence.

Such theories are typically (but not always) based upon probability theory, the mathematical theory of the acceptability of a statement or proposition, or of its likelihood. The standard account, first axiomatized in 1933 by Andrej Kolmogorov (b. 1903) [1.160], can be summarized as follows: Given sentences s and t, probability is a real-valued function, Pr, such that

1 $Pr(s) \geq 0$,
2 $Pr(t)=1$, if t is a tautology
3 $Pr(s \vee t)=Pr(s)+Pr(t)$, provided that s and t are mutually exclusive (i.e. $\sim(s \,\&\, t)$)
4 $Pr(s \mid t)=Pr(s \,\&\, t)/Pr(s)$, provided that $Pr(s) \neq 0$.

Default logics, which permit the acceptance or rejection of certain types of default inferences in the absence of information to the contrary, provide one type of non-monotonic alternative to probabilistic theories.

Defeasible theories often give rise to so-called 'applied logics', including theories of belief revision and theories of practical rationality. Theories of belief revision (for example in [1.123]) are typically designed in such a way as to model changes in one's belief set which come about both as a result of the acceptance of new beliefs and the revision of old beliefs. Thus, if K is a consistent belief set closed under logical consequence, then for any well-formed sentence, S, one of the following three cases will obtain:

1 S is accepted, i.e. $S \in K$ (and $\sim S \notin K$);
2 S is rejected, i.e. $\sim S \in K$(and $S \notin K$); or
3 S is indetermined, i.e. $S \notin K$ and $\sim S \notin K$.

Epistemic changes may then be of any of the following three types:

1 Expansions: given that S is indetermined, either accept S (and its consequences) or accept $\sim S$ (and its consequences);
2 Contractions: given that S is accepted (or that $\sim S$ is accepted, i.e. S is rejected), conclude that S is indetermined;
3 Revisions: given that S is accepted (or that $\sim S$ is accepted, i.e. S is rejected), conclude that S is rejected (or that $\sim S$ is rejected, i.e. S is accepted).

Theories of practical rationality (for example in [1.159]) typically include both decision theory (the theory of choice selection under various conditions of risk and uncertainty, given that each option has associated with it an expected probability distribution of outcomes, gains and losses), and game theory (the theory of choice selection by two or more agents or players when the outcome is a function, not just of one's own choice or strategy, but of the choices or strategies of other agents as well). Such theories may be either bounded or not, depending upon whether they take account of possible cognitive limitations of the decision-makers.

CHAPTER 2

Philosophy of mathematics in the twentieth century

Michael Detlefsen

INTRODUCTION

Philosophy of mathematics in the twentieth century has primarily been shaped by three influences. The first of these is the work of Kant and, especially, the problematic he laid down for the subject in the late eighteenth century. The second is the reaction to Kant's conception of geometry that arose among nineteenth-century thinkers and which centred first on the discovery of non-Euclidean geometries in the 1820s. The third is the new discoveries in logic that emerged with increasing rapidity and force during the latter half of the nineteenth century. In one way or another, the main currents of twentieth-century philosophy of mathematics—and, in particular, the so-called logicist, intuitionist and formalist movements—are all attempts to reconcile Kant's revolutionary plan for mathematical epistemology with the equally revolutionary ideas of Gauss, Bolyai and Lobatchevsky in geometry, and the powerful ideas and techniques developed by Boole, Peirce, Peano, Frege and other nineteenth-century figures in logic.

To understand twentieth-century philosophy of mathematics, it is therefore necessary first to have some knowledge of Kant's ideas and of the ideas that were at the heart of the nineteenth-century reactions to his views. We shall therefore devote the remainder of this introduction to surveying these ideas.

We begin with Kant and the *Problematik* he established for mathematical epistemology. This *Problematik* was focused on the reconciliation of two apparently incompatible features of mathematical thought: namely, its rich *substantiality* as a science, which gives it the

appearance of something that arises from sources external to the human intellect, and its apparent certainty or *necessity*, which gives it the appearance of something that is independent of the one external source which is best founded and understood—namely, sensory experience.

To resolve this difficulty, Kant formulated a theory of knowledge which imported much of what had traditionally been thought of as information arising from external sources (specifically, the basic spatial characteristics of sensory thought, and the temporal characteristics of both sensory and non-sensory thinking) into the human mind itself, representing it as the product of certain deep, standing traits of human cognition. At the centre of this theory was a certain conception of judgement which represented the intersection of two different schemes for classifying propositions. On the first of these, propositions were sorted according to the type of knowledge of which they admitted; those which required sensory experience were called *a posteriori*, those which did not were called *a priori*. On the second, they were sorted according to whether or not their predicate terms were contained in their subject terms (in the sense that one *thinking* the subject term would, as a part of that very act itself, also *think* the predicate term). Those judgements in which the subject term contained the predicate term in this sense were to be called *analytic*. Those in which no such containment obtained were either falsehoods, because there was no connection between the subject and predicate concepts at all, or they were *synthetic* truths. In true synthetic judgements, the subject and predicate concepts were joined not by a relation of containment, but rather by a relation of *association*. The association of a predicate with a subject provided for their being thought together in tandem, though it did not, like containment, require that a thinking of the predicate term of a judgement be a constituent part of any thinking of its subject term (cf. [2.58] for a good discussion of the Kantian doctrine of concepts, specifically in relation to his conception of intuition).

Kant erected his mathematical epistemology upon these distinctions between a priori and a posteriori and analytic and synthetic judgements. He attempted to explain what he referred to as the 'certainty' or 'necessity' of mathematical judgements by showing that our knowledge of them is a priori. Such knowledge, he argued, derives from two standing capacities of the human mind. One of these, which Kant referred to as our a priori intuition of space, was taken to function as a formal constraint on sensory experience by forcing it to be represented in a Euclidean space of three dimensions. The other, the so-called a priori intuition of time, served formally to constrain both sensory and non-sensory experience by representing it as temporally ordered. Both the a priori intuition of space and the a priori intuition of time therefore functioned to control the senses rather than the other way round. It was because of this that Kant believed judgements arising from them (i.e. the

judgements of geometry and arithmetic) to be impervious to falsification by sensory experience.

This, in brief, was Kant's proposal for accounting for the necessity of mathematics. He proposed to account for its substantiality by establishing that its judgements are synthetic rather than analytic in character. If mathematical judgement is synthetic in character, then it cannot be seen as consisting in the mere apprehension of a *containment* relation between its subject and predicate concepts. Rather, it must be seen as the fusion in thought of two analytically unrelated concepts through one of two means: either the conjunction of concepts provided for by repeated sensory experience, or the invariant and inevitable association provided for by an a priori structuring of our minds in such a way as to bring the two together *in thought*. Such a joining of analytically unrelated concepts, in which the thinking of the predicate concept is not, logically speaking, strictly required for the thinking of the subject concept, was, in Kant's view, the essential ingredient of substantiality in judgement. This notion of analytically unrelated concepts necessarily joined in thought enabled Kant to frame an account of the substantiality of mathematical judgements which would allow mathematical judgement to be necessary but, at the same time, not limit the degree and kind of the informativeness of mathematical judgements to the degree and kind of complexity that logical containment relations are capable of displaying. In Kant's estimation, this latter was a limitation that it was important to avoid.

Kant adopted a similarly synthetic view of the nature of mathematical *reasoning*. He maintained that mathematical (as opposed to logical or analytical) inference possesses the same rich substantiality of character that distinguishes mathematical from logical or analytical judgement. He also argued (cf. [2.86], 741–7) that the connection between the premiss(es) and conclusion of a mathematical inference calls for synthetic rather than analytic means of bonding.

To illustrate the point, he elaborated upon an elementary case of geometrical inference; namely, that inference in ordinary Euclidean geometry which takes one from a premiss to the effect that a given figure is a triangle to the conclusion that the sum of its interior angles is equal to that of two right angles. He maintained (Ibid.) that no amount of analysis of the concept of a triangle could ever reveal that its interior angles sum to two right angles. Rather, he said, in order to arrive at such a conclusion (i.e. a conclusion that extends our knowledge of triangles beyond what is given in the definition of the concept itself) we must rely primarily not on the definition of the concept, but on the means by which triangles are presented to us in intuition. In other words, we must construct a triangle in intuition (i.e. represent the object which 'corresponds to' [Ibid., p. 742] the concept of a triangle), and then extract the conclusion

not from the mere concept of a triangle but rather from *the universal conditions governing the construction of triangles* (Ibid., pp. 742, 744) in our intuition. 'In this fashion', said Kant, the mathematical reasoner arrives at his conclusion 'through a chain of inferences guided throughout by intuition' (Ibid., p. 745).

These, in brief, are Kant's proposals for the resolution of what he took to be the central problems facing the philosophy of mathematics. But though the problems themselves have remained a staple of twentieth-century thinking on the subject, Kant's particular proposals for their resolution have not. What caused this decline in the popularity of Kant's ideas was, primarily, the emergence of challenges to his conception of geometry and his view of the relation between geometry and arithmetic that arose in the nineteenth century. It is to these ideas that we now turn, beginning with geometry.

On Kant's conception, geometry was the product of an a priori intuition of space which specified the space in which human spatial experience was 'set', so to speak. The character of this a priori visual space was that spelled out in the Euclidean axioms for three-dimensional space. In calling Euclidean three-dimensional space the space of human visual experience, one does not mean, of course, that it is the only space that is intelligible or logically coherent to the human mind. Visualizability is one thing, intelligibility or logical coherence another. Kant's position was that Euclidean three-dimensional space is the only space that is *visualizable* by humans (cf. [2.57] for a useful discussion of Kant's view of geometry).

Not long after Kant elaborated his views in the *Critique of Pure Reason,* mathematicians expressed doubts about them. Gauss, for example, clearly stated his doubts concerning the a priori character of geometry in a letter written in 1817 to Olbers (cf. [2.60], 651–2). He restated the same view in an 1829 letter to Bessel (cf. [2.59], VIII:200) and added that it had been his view for nearly 40 years. In (my translation of) his words:

> My innermost conviction is that geometry has a completely different position in our a priori knowledge than arithmetic…we must humbly admit that, though number is purely a product of our intellect, space also has a reality external to our intellect which prohibits us from being able to give a complete specification of its laws a priori.[1]

Later, in a letter written in 1832 to Bolyai's father (cf. [2.59], VIII: 220–21), he reiterated this view, saying that Bolyai's results provided a proof of the incorrectness of Kant's views.

> It is precisely in the impossibility of deciding a priori between Σ [Euclidean geometry] and S [the younger Bolyai's non-Euclidean

> geometry] that we have the clearest proof that Kant was wrong to claim that space is only the form of our intuition. [Brackets and translation mine]

There thus arose among nineteenth-century thinkers the belief (given special impetus by the work of Bolyai and Lobatchevsky) that there are fundamental epistemological differences between geometry and arithmetic. Put briefly, the difference is that arithmetic is more and geometry less central to human thought and reason. Arithmetic, on this view, was taken to be wholly a product or creation of the human intellect; geometry, on the other hand, was taken to be determined at least in part by forces external to the human intellect. The difference was implied by a broad epistemological principle (which we might refer to as the *creation principle*) to the effect that what the mind creates or produces of itself is better known to it than that which comes from without.

Belief in the epistemological asymmetry of arithmetic and geometry (though not necessarily Gauss's particular conception of its character) thus became a central tenet of nineteenth-century thinking concerning the nature of mathematical knowledge. It also became a prime force shaping the major movements of twentieth-century philosophy of mathematics. In the main, two basic kinds of reactions emerged, corresponding to the two basic ways of accommodating this asymmetry. One was to retain a Kantian conception of arithmetic (as based on an a priori intuition of time) and adopt a non-Kantian conception of geometry (as based on an a priori intuition of space). The other was to take a non-Kantian view of arithmetic while retaining a Kantian conception of geometry. The former of these two tactics was essentially that which was adopted by the intuitionists Brouwer and Weyl, while the latter became the central idea motivating the logicism of Frege and Dedekind. Hilbert's finitist programme, the third main movement of twentieth-century philosophy of mathematics, in a way adopted and in a way rejected both. It maintained both the epistemological symmetry of arithmetic and geometry and their fundamentally a priori character. It rejected, however, Kant's proposed a priori intuitions of space and time as their bases.

The powerful confirmation of belief in the epistemological asymmetry of arithmetic and geometry that was provided by the nineteenth-century discovery of non-Euclidean geometries was therefore a major factor contributing to the decline of Kant's positive views in the philosophy of mathematics and the emergence of major alternatives in the twentieth century. The second major factor contributing to the weakening of Kant's influence in twentieth-century philosophy of mathematics was the dramatic development of logic during the latter part of the nineteenth and the early part of the

twentieth centuries. This included the introduction of algebraic methods by Boole and DeMorgan, the improved treatment of relations by Peirce, Schröder and Peano, the replacement of the Aristotelian analysis of form based on the subject-predicate relation with the more fecund analysis of form based on Frege's general notion of a logical function, and the advances in formalization brought about by the introduction (by Frege, Russell and Whitehead, and Peano) of precisely defined and managed symbolic languages and systems.[2]

These developments took logic to a point well beyond what it was in the time of Kant, and this caused some to judge that it was the relatively underdeveloped state of logic in Kant's time that was primarily responsible for his belief in the need for a *synthetic* basis for mathematical judgment and inference. Russell, for one (cf. [2.120], [2.123], [2.124]), took such a position, arguing that though Kant's views may have seemed reasonable given the sorry state of logic in his day, they would never have been given a serious hearing had our knowledge of logic been then what it is now. (N.B. But though Russell saw the enrichment of the analysis of logical form brought about by the modern logic of relations and the functional conception of the proposition as being of particular importance to the correction of Kant's deficiencies, he also believed that certain developments in mathematics proper were of great importance. Chief among these were (i) the arithmetization of analysis by Weierstrass, Dedekind and others; and (ii) the discovery by Peano of an axiomatization of arithmetic. These led to what Russell regarded as a codification of pure mathematics within a certain axiomatic system of arithmetic (viz. second-order Peano arithmetic), and so provided for its 'logicization'. Russell reckoned the significance of these developments for Kant's philosophy of mathematics to be as great as that of the discovery of non-Euclidean geometries (cf. [2.120], [2.123].)

For the most part, Russell's views on these matters were taken over by the logical empiricists, who, like Russell, were much impressed with the new logic, and who were also attracted to a logicism like Russell's,[3] because it allowed them to resolve the difficulties that mathematics had traditionally posed for empiricist epistemologies.[4] The new logic, then, in being seen as the basis for the working out of Russell's sweeping form of logicism, eventually led to the resurgence of empiricist epistemologies for mathematics, and these, quite clearly, represented a significant departure from Kantian mathematical epistemology. In addition, it posed what has proven to be an enduring challenge to the Kantian view that mathematical *reasoning* is essentially distinct from logical reasoning.[5]

This completes our synopsis of the major influences shaping twentieth-century philosophy of mathematics. The longer story, which we shall now

tell in greater detail, is, for the most part, the story of the ebb and flow of Kant's ideas as they met and interacted with new developments in geometry, logic, science and philosophy.

THE EARLY PERIOD AND THE DEVELOPMENT OF THE THREE 'ISMS'

We begin our discussion with the first three decades (what we are calling the 'early period'), which, if it was not *the* most active productive period, was certainly one of the most such in the entire history of the subject. The major developments of this period were the three great 'isms' of recent philosophy of mathematics: logicism, intuitionism and (Hilbert's) formalism. All of these, we shall argue, were profoundly influenced by Kantian ideas. In the case of logicism, however, one must take care to distinguish Frege's from Russell's version. Frege's had much closer ties to Kantian epistemology than did Russell's. Indeed, it attempted to retain many of Kant's most important ideas, including, as we shall see, certain of his ideas regarding the nature of reason.

Logicism

Frege was moved by the discovery of non-Euclidean geometries, and dedicated to the task of explaining what he took to be the main upshot of this discovery—namely, the asymmetry between arithmetic and geometry as regards their basicness to human thought. Geometrical thinking, though widely applied in human thought, was not so widely applied as to suggest that it is not based on a Kantian type of a priori intuition. Thus, Frege supported Kant's geometrical epistemology (cf. [2.49], section 89). Arithmetic, on the other hand, was too pervasively applicable in human thought to be ascribed plausibly to the working of a similar faculty of intuition. No, its epistemological source must be sought elsewhere—ultimately, as Frege saw it, in a reconceived faculty of reason.

The basics of this viewpoint were evident in Frege's writings from the very start. Thus, already in his 1873 doctoral dissertation, he emphasized that 'the whole of geometry rests, in the final analysis, on principles that derive their validity from the character of our intuition' (cf. [2.46], 3, my translation). And, in his 1874 *Habilitationsschrift* [2.47], he expanded this observation to include his view of the relation between geometry and arithmetic *vis à vis* their dependency on intuition.

> It is quite clear that there can be no intuition of so pervasive and abstract a concept as that of magnitude (Größe). There is therefore a noteworthy *(bemerkenswerter)* difference between geometry and arithmetic concerning the way in which their basic laws are grounded. The elements of all geometrical constructions are intuitions, and geometry refers to intuition as the source of its axioms. Because the object of arithmetic is not intuitable, it follows that its basic laws cannot be based on intuition.[6]

The same basic point concerning the 'unintuitedness' of the objects of arithmetic is made in the *Grundlagen,* where Frege remarks that:

> In arithmetic we are not concerned with objects which we come to know as something alien from without through the medium of the senses, but with objects given directly to our reason and, as its nearest kin, utterly transparent to it.
>
> [2.49, Section 105]

The same basic contrast between geometry and arithmetic is drawn in sections 13 and 14 of the *Grundlagen* [2.49]. There Frege broached the question of the relative places occupied in our thinking by empirical, geometrical, and arithmetical laws. His conclusion is that arithmetic laws are deeper than geometrical laws, and geometrical laws deeper than empirical laws. He arrives at this conclusion by conducting a thought experiment in which he considers the cognitive damage that one might expect to be done by denying each of the various kinds of laws. Denying a geometrical law, he concludes, stands to do more extensive damage to a person's cognitive orientation than denying a physical law. For it would lead to a conflict between what people can conceive and what they can spatially intuit. It would bring severe disorientation to a person's cognition. It would force them, for example, to deduce things that formerly they had been able just to 'see'. And it would even make the deductions strange and unfamiliar. It would not, however, result in a global breakdown of their rational thinking. Such global breakdown in one's rational functioning is rather that which would follow from a denial of arithmetical law. Denying an arithmetical law would not only keep one from seeing what he had formerly been able to see, it would, according to Frege, prohibit his engaging in deduction or reasoning of any sort. In his words, it would bring about 'complete confusion', so that 'even to think at all would seem no longer possible' (Ibid.).

Frege sought to explain this projected global breakdown in rational thought by arguing that the scope of arithmetical law, unlike that of physical and geometrical law, is universal. It governs not only that which

is physically actual and that which is spatially intuitable, but, indeed, all that which is *numerable*—and that, according to Frege, is the widest range possible, extending to all that which is in any coherent way thinkable or conceivable.[7] The laws of arithmetic must, therefore, he concluded, 'be connected very intimately with the laws of thought' (Ibid.)—that is, the laws of logic.[8]

This alleged difference in the pervasiveness to thought of arithmetic and geometry thus became, in Frege's thinking, the (or at least a) fundamental datum for the philosophy of mathematics. He also believed it to be a datum Kant had overlooked. For, had he been aware of it, Frege felt sure, Kant would never have tried, as he did, to stretch essentially the same epistemology to cover both arithmetic and geometry. Rather, he would have tried to do justice to the 'observable' differences in depth-to-rational-thought of arithmetic and geometry.

Kant's ultimate shortcoming, Frege believed, was that he had acknowledged only two basic sources of knowledge—sensation and understanding. This allowed room only for a distinction between sensory and a priori knowledge. It did not allow for a distinction—at least not a distinction of kind—between different subspecies of a priori knowledge. Frege, on the other hand, distinguished between sensory experience, the source of our knowledge of natural science, intuition, the source of our geometrical knowledge, and reason (cf. [2.49], sections 26, 105), which Frege described as the source of our arithmetical knowledge. This modification of Kant's general epistemology was, Frege believed, necessary if one was to account for the perceivable differences in the relative pervasiveness of arithmetic and geometry.[9]

(N.B. Actually, it is not clear that Kant's epistemology did not enable him to do something of the same sort. Certainly it *did* distinguish two types of experience (cf. [2.86], 37–53), 'inner' and 'outer', and noted that the one (viz., inner) made use of intuitional resources (viz., the a priori intuition of time) that are more pervasive than those (viz., the a priori intuition of space) upon which the other is based. Adding to this the fact that Kant maintained that arithmetical thinking is based on the more pervasive intuition of time and geometrical thinking on the less pervasive intuition of space, it would seem that the distinction between inner and outer experience in Kant is capable of effecting something of at least the same general kind of asymmetry between arithmetic and geometry that Frege believed to be so important to mathematical epistemology. Frege seems never to have considered this point.

We add this remark, however, mainly as an aside. For, clearly, there are important differences between Frege and Kant concerning the pervasiveness of arithmetic. Kant, for example, despite acknowledging arithmetic to be widely applicable, none the less held it to be limited to

that which is *experienceable*. He did not take it to apply to the whole of what is (rationally) imaginable or *conceivable*. Consequently, though he judged arithmetical law to be a priori in character, he also judged it to be synthetic. Frege, on the other hand, believed arithmetic to apply to all that is conceivable, and it was precisely in this departure from Kant that he was led to regard it as analytic rather than synthetic in character.)

Frege thus disagreed with Kant concerning the pervasiveness to rational human thought of arithmetical thinking. This disagreement cannot, however, be taken at face value in explaining why Kant held a synthetic and Frege an analytic conception of arithmetic. For the two employed different conceptions of the notions of analyticity and syntheticity. Thus, to comprehend better the true differences separating Kant and Frege, we must look more carefully at the definitions each used in formulating the key notions of his position.

Kant defined an analytic truth as a truth in which the predicate 'belongs to' the subject as something 'covertly contained' in it, and a synthetic truth as one that is not analytic (cf. [2.86], 9–11). He did not characterize the analytic/synthetic distinction, as he did the a priori/a posteriori distinction, in terms of the characters of the possible justifications of a judgement. Frege, on the other hand, did exactly that. In his scheme (cf. [2.49], sections 3, 17, 87–8), both the analytic/synthetic and the a priori/a posteriori distinctions are parts of a classificatory system regarding the different kinds of *justifications* a given judgement might have.

Each truth, Frege believed, possesses a kind of *canonical proof* or justification. This is a proof which, in its ultimate premisses, goes all the way back to the 'primitive truths' of the subject to which the theorem belongs. It gives 'the ultimate ground upon which rests the justification for holding [the theorem proven] to be true' (Ibid., section 3). It thus presupposes an ordering of truths, and its objective is precisely to retrieve that segment of the given ordering which links the proposition to be proven to those ur-truths of its subject which are responsible for its truth. It aims, in other words, at revealing what might be called the *grounds* of the proven proposition's truth—its Leibnizian *Sufficient Reason,* as it were (Ibid., sections 3, 17).

A proposition or judgement is said to be analytical, in this scheme, if its canonical proof contains only 'general logical laws' and 'definitions' (Ibid., Section 3). It is said to be synthetic if its canonical proof contains at least one premiss belonging to 'some special science' (Ibid.). It is considered a posteriori if its canonical proof includes an 'appeal to facts, i.e. to truths which cannot be proved and are not general' (Ibid.). And, finally, it is considered to be a priori if its canonical proof uses exclusively 'general laws, which themselves neither need nor admit of proof' (Ibid.)

(in other words, if knowledge of it can arise from the Fregean faculty of reason alone).[10]

Frege believed that finding the canonical proofs of arithmetical truths would reveal an intimate connection between them and the basic laws of thought (i.e. the 'general logical laws').[11] At the same time, however, he was keenly aware of the Kantian objection to such a proposal; namely, that it makes it difficult to account for the epistemic productivity or substantiality of arithmetic. Indeed, immediately after having broached the view that arithmetic is analytic in section 15 of the *Grundlagen* [2.49], Frege went on in section 16 to note that the chief difficulty facing such a view is to explain how 'the great tree of the science of number as we know it, towering, spreading, and still continually growing' can 'have its roots in bare identities'. He thus clearly saw his main task as that of explaining how analytic judgement and analytic inference can yield an epistemic product having the robustness that arithmetic appears to have.

His response can be seen as divided into two parts. The first of these consists in the giving of an account of the 'objectivity' of analytic judgements that does not appeal to sensation or intuition. The second concerns the more general problem of explaining how one might get a conclusion that extends the knowledge represented by the premisses of an inference out of premisses that can be inferentially manipulated only by purely logical means.

Regarding the former, Frege's idea was to ascribe special properties to concepts, or to the objectively existing *thoughts* which, via the context principle (the principle that it is only in the context of a proposition *(Satz)* that words have meaning, cf. [2.49], section 60), are prior to them. Numbers were then to be defined in terms of concept extensions, and concept extensions to be treated as 'logical objects' (which we somehow grasp by grasping the concepts of which they are extensions). The epistemologically salient features of this arrangement were summed up in the following remark from the *Grundlagen* (Ibid., section 105).

> reason's proper study is itself. In arithmetic we are not concerned with objects which we come to know as something alien from without through the medium of the senses, but with objects given directly to reason and, as its nearest kin, utterly transparent to it.
>
> And yet, for that very reason, these objects are not subjective fantasies. There is nothing more objective than the laws of arithmetic.[12]

In later writings, Frege elaborated a bit—but only a bit—on his notion of concept extensions as *logical objects*. He wrote, for example, that:

> it is futile to take the extension of a concept as a class, and make it rest, not on the concept, but on single things…the extension of a concept does not consist of objects falling under the concept, in the way, e.g., that a wood consists of trees… it attaches to the concept and to the concept alone…the concept takes logical precedence to its extension.
>
> (cf. [2.53], 455).

Thus, what made a class into a logical object, in Frege's view, was only its relation to the concept of which it formed the extension. He had ultimately, however, to establish the sense in which logical objects exist, since, in his view, they were not actual (i.e. not spatial or 'handleable'). Here he had only analogies to offer, citing such examples as the axis of the earth and the centre of mass of the solar system (cf. [2.49], section 26). These illustrated his generally negative characterization of logical objects as objects 'independent of our sensation, intuition and imagination, and of all construction of mental pictures, memories and earlier sensations, but not…independent of reason' (Ibid.).13

Frege had also to establish that logical objects deserve to be called 'logical'. This he did not do in the *Grundlagen,* being at that time unsure whether he needed concept extensions or just concepts.[14] He pursued the matter to a (for him) satisfactory end only in the 1891 lecture 'Function und Begriff [2.51], where he argued (i) that the notion of concept-extension can be reduced to that of the range-of-values of a function; and (ii) that this latter notion is clearly a logical notion.

Among the more important things that Frege's belief in the logical precedence of concepts to their extensions allowed him to do was to reduce knowledge of infinities to logical knowledge. Along with this he had also to accept a restriction on how we come to *acquire* concepts; namely, that we do so by means other than abstraction from the particulars falling under them (cf. [2.49], sections 49–51). Such a view of concept acquisition was of the utmost importance to his logicism. For, were concepts to be obtainable only via such a process of abstraction, knowledge of the number concept would likewise be obtainable only through prior knowledge of the particulars falling under it. If that were so, however, one would have to give a prior account of how it is that we come by knowledge of the particulars from which knowledge of the abstracted concept is derived. And in order to keep this account from destroying the 'logical' character of numbers, one would have to make sure that it made no appeal to the likes of sensation or Kantian intuition. Moreover, even if it were successful in avoiding appeals to Kantian intuition, such an abstractive account of concept acquisition would cause severe problems for the knowledge of infinite sets. For it is hardly plausible to believe that we could either obtain separate intuitions for each member of an infinite

collection or be given infinite sets of particulars in the space of a single intuition of their members (through devices such as, say, Kant's so-called 'unity of synthetic apperception').[15]

Frege's logicist treatment of number therefore relied heavily on the idea that concepts are given prior to and independent of their extensions. This, indeed, seems to be have been the leading idea behind his notorious Rule V, the principle that every concept has an extension (or, to put it in its original form, the principle that all and only s are s if and only if the extension of is identical to the extension of ψ).[16]

The discovery by Russell (cf. [2.119]) that this way of thinking of the relationship between concepts and (logical) objects is subject to paradox therefore threw Frege's entire 'improvement' of Kant's arithmetical epistemology into crisis. For without a principle that makes concepts prior to their extensions, a Fregean philosophy of arithmetic would have great difficulty in developing an appropriately non-intuitional model of cognition for our knowledge of concept extensions. And without a non-intuitional model of our knowledge of concept extensions, the major novelty (i.e. the major non-Kantian element) would be missing from Frege's proposed explanation of the epistemic robustness or substantiality of arithmetic.

Russell's discovery thus raised the problem of how we might come to apprehend logical objects (and thus numbers), even if it is assumed that they exist. Without a Frege-type scheme of comprehension, which sees apprehension of numbers as derived from apprehension of concepts, and which allows concepts to be apprehended without any prior non-conceptual apprehension of particulars, one is hard-pressed to avoid at least some minimal appeal to non-conceptually based knowledge of sets or extensions—a knowledge which is hard to account for without making some appeal to sensation or intuition.[17] Russell's paradox therefore raised grave problems for the epistemology of Frege's logical objects.

But even supposing these problems to have been solved, there were, by Frege's own admission (indeed, his own insistence!), serious difficulties still to be overcome in explaining the epistemic productivity of mathematical *inference*. To manage these, Frege appealed to the general phenomenon of *Sinn* and to the possibility of rearranging (or 'recarving') the contents of a proposition in such a way as to expose contents that had been hitherto undetected.

Concepts featured prominently in this explanation too. In particular, it included an appeal to an assumed relationship between concepts and propositions which allows a proposition to be both understood and known even though not all the concepts contained in it are apprehended. This crucially important feature of the relationship between propositions and their constituent concepts was taken to be

based on the principles that (i) in order to apprehend a proposition, one need only know a *definition* of its immediate constituent concepts; and that (ii) knowing a definition of a concept does not require that all content tacit in it be apprehended. It is the recovery of tacitly contained content (i.e. discovery of its presence and character) that thus allows the conclusion of an analytic inference to represent something more, by way of cognitive accomplishment, than is represented by the apprehension and knowledge of its premisses. As Frege himself put it, the identification and utilization of such content amounts to something more than merely 'taking out of the box again what we have just put into it' (Ibid., Section 88).[18] For what we put into an inferential 'box' is the knowledge of concepts we use in order to arrive at understanding and knowledge of its premises. What, on Frege's account, we are capable of extracting from such a box is not only judgements formed from those concepts, but also judgements formed from concepts identified, indeed *formed*, through the 'carving up' or conceptual rearrangement of the premises.[19]

However, if Frege required analytic inference to be epistemically productive, he also required (at least some of) it to be rigorous. Therefore, in some sense, he demanded that analytical judgement be *incapable* of concealing content. Indeed, he himself insisted that his logicism required the giving of utterly rigorous proofs for the laws of arithmetic. It is 'only if every gap in the chain of deductions is eliminated with the greatest care', he said, that we can 'say with certainty upon what primitive truths' they rest (Ibid., Section 4; cf. also the introduction to [2.52]). And it is only through seeing with certainty the truths upon which the truths of arithmetic rest that we would be in a position to judge whether or not those grounds are logical in character.

What Frege seems not to have seen so clearly, however, is that we can be certain that a canonically proven proposition is analytic only to the extent that we can be certain that its premisses do not tacitly contain any synthetic content. At any rate, how certainty on this score is to be attained is something about which he seems to have said little. He firmly believed that there are propositions—the so-called 'basic laws' of arithmetic—that are at once so rich as to be capable of delivering the whole of arithmetic and also so clearly analytic as to self-evidently conceal no synthetic content. What he took to be the justification of this confidence is less clear.

(N.B. Leibniz, the original logicist, also believed in such a layer of analytic truths. However, for him, things were different. For, in the first place, he believed that all propositions are analytic. Second, the propositions he saw as making up the 'basic laws'—namely, the so-called logical identities of the form 'A is A'—were transparently analytic. This is

so because, for Leibniz, analyticity consisted in containment of the predicate of a proposition in its subject, and propositions of the form 'A is A' satisfy this containment requirement in a manner in which none clearer or more certain can be conceived. Leibniz therefore had a natural stopping point for his reduction to analytic truth. Frege, on the other hand, having adopted a more complex and sophisticated definition of analyticity, seems to have lost the ability to identify a class of truths which were as clearly and certainly analytic as Leibniz's 'identities'. As a result, he lacked as clear a point at which to terminate the reduction of arithmetic laws to analytic truths.)

Frege's conception of mathematical inference was thus faced with two apparently competing demands: on the one hand, the need to endow analytic judgments with tacit content so as to enable analytic inference to be epistemically productive; and, on the other, the need to restrict the mechanisms producing tacit content in such a way as to guarantee that synthetic content can never be tacitly contained in what passes for analytic content. In the end, I believe, he failed to meet these two demands adequately. He did not succeed in providing a set of basic laws and a criterion of tacit content the pair of which were guaranteed to permit only the production of analytic truths as tacit contents of the basic laws. Nor did he manage to ensure that the epistemic productivity sustainable by means of his mechanisms of tacit content production are capable of matching those which may be observed to hold in arithmetic.

The first failure was clearly illustrated by Russell's paradox, which shows that the latent content concealed by Frege's axioms (in particular, his axiom of comprehension) could include not only synthetic truths, but even analytical falsehoods! The second failure became the pivotal feature of the intuitionists' critique of logicism, which will be discussed later.

Russell's logicism was quite different from Frege's. In the first place, it was not motivated primarily by the discovery of non-Euclidean geometries with its attendant belief in the epistemological asymmetry between geometry and arithmetic. Nor was it based on belief in such things as logical objects, and the associated division of cognition into faculties of sense, intuition and reason. Nor, finally, did it restrict its logicism to arithmetic, but, rather, extended it to the whole of mathematics, and even to certain areas outside traditional mathematics.[20] Rather, it took as its starting points (i) a certain general definition of mathematics; (ii) a methodological principle to pursue ever further generalization in science; and (iii) a belief that pursuing this principle in mathematics would eventually lead one to a most general science of all, namely, logic.[21] It was fuelled in these pursuits by the then rapid and impressive advances in symbolic logic.

In the opening paragraph of *The Principles of Mathematics* ([2.120], 3),[22] Russell offered the following definition of pure mathematics: 'Pure mathematics is the class of all propositions of the form "*p* implies *q*", and neither *p* nor *q* contains any constants except logical constants'. He then went on to describe his logicist project as that of showing 'that whatever has, in the past, been regarded as pure mathematics, is included in our definition, and that whatever else is included possesses those marks by which mathematics is commonly though vaguely distinguished from other studies' (Ibid.). Russell also maintained that, in addition to asserting implications, propositions of pure mathematics are characterized by the fact that they contain variables (Ibid., p. 5), indeed, variables of wholly unrestricted range (Ibid., p. 7).

Russell planned to defend this last claim, which he acknowledged as being highly counterintuitive, by showing that even such apparently variable-free statements as '1+1=2' can be seen to contain variables once their true meaning and form is revealed. The discovery (or, better, *recovery*) of the true meaning and form of such statements was made possible by the vast enrichment of the basic stock of logical forms made available through the work of Peirce, Schröder, Peano and Frege. Using this work, Russell produced analyses of the deep forms of ordinary mathematical statements. '1+1=2', for example, was analysed as 'If *x* is one and *y* is one, and *x* differs from *y*, then *x* and *y* are two.' Analysed in this way, Russell maintained, the supposedly non-implicational, variable free '1+1=2' is seen both to contain completely general variables and to express an implication, just as his logicist theory predicted would be the case (Ibid., p. 6).

Of course, 'if *x* is one and *y* is one, and *x* and *y* are different, then *x* and *y* are two' does not express a genuine proposition at all since it contains free variables. It expresses instead what might be called a proposition form or a proposition schema. Russell called it a '*type* of proposition', and went on to say that 'mathematics is interested exclusively in *types* of propositions' (Ibid., p. 7) rather than in individual propositions *per se*. On this view, the business of mathematics is to determine which propositions can be generalized (i.e. which constants can be turned into variables), and then to carry this process of generalization out to its maximum possible extent (Ibid., pp. 8, 9). This maximum will have been reached when we have penetrated to a level of propositions whose only constants are *logical* constants and whose only undemonstrated propositions are the most basic truths whose only constants are logical constants (Ibid., p. 8).[23] The logical constants themselves, as a class, were to be characterized only by enumeration. Indeed, by their very nature they admitted only of this kind of characterization, since any other kind

of characterization would be forced to make use of some element of the class to be defined.

At bottom, then, Russell's logicism was motivated by a view of mathematics that saw it as the science of the most general formal truths; a science whose only indefinables are those constants of rational thought (the so-called *logical* constants) that have the widest and most ubiquitous usage and whose only indemonstrables are those propositions which set out the most basic properties of those indefinable terms (Ibid). In his view, this provided the only precise description of what philosophers have had in mind in describing mathematics as an a priori science (Ibid). Mathematics is thus in the business of generalization. Its aim is to identify those truths that remain true when their non-logical constants are replaced by variables (Ibid., p. 7). This process of generalization may require some analysis in order to find the genuine form of the sentence to be generalized. But once that form is found, the generalization process should ultimately lead to the realization that the mathematical truth in question expresses a formal truth whose variables are completely general and whose only constants are logical constants.

Ideally, proper method in mathematics requires pursuit of this process of generalization to the ultimate degree.[24] At that point, Russell believed, we will find formal truths of maximum generality—truths of a generality so great as to render them incapable of further generalization—truths, that is, that are so general that they would become non-truths were any of their constants to be replaced, even through conceptual analysis, by variables. This, in Russell's opinion, was the only point at which the method of mathematics (i.e. the pursuit of maximal formal generalization) can properly and naturally be brought to a close. He also believed that it is in this domain of formal truths of the utmost generality, and in this domain alone, that we can rightly expect to meet what are properly regarded as *laws of logic*.

According to Russell, these laws are justified inductively from their consequences.

> in mathematics, except in the earliest parts, the propositions from which a given proposition is deduced generally give the reason why we believe the given proposition. But in dealing with the principles of mathematics, this relation is reversed. Our propositions are too simple to be easy, and thus their consequences are generally easier than they are. Hence we tend to believe the premises because we can see that their consequences are true, instead of believing the consequences because we know the premises to be true…thus the method in investigating the

> principles of mathematics is really an inductive method, and is substantially the same as the method of discovering general laws in any other science.[25]

Thus, contrary to what Kant had maintained, the pursuit of greater generality (or what Kant referred to as 'unification') has a natural and fairly inevitable stopping point; specifically, that level of judgements having broad scope, entirely general variables and utterly ubiquitous constants.

Frege and Russell, then, though they agreed in their rejection of Kantian intuition as the basis of mathematical knowledge, none the less differed with regard to their estimates of the proper scope of logicism and the nature and origins of its basic laws. They also differed on the important question of our knowledge of the infinities with which mathematics deals, and of how, exactly, that knowledge is related to our knowledge of concepts.

Unlike Frege, Russell did not believe that concepts alone can give rise to extensions or sets. Indeed, he responded to his own antinomy by offering a conception of set which assumed a class of individuals as given *prior to* the generation of sets by concepts. In his view, before there can be a rich universe of sets, there must first be a totality of individuals that is given by means other than grasp of a concept. Using this domain of individuals as a base, comprehension by concepts (or what Russell referred to as 'prepositional functions') was then supposed to operate according to predicative principles of collection. There was thus an order of 'priority' of *types* or levels induced among entities, with the domain of individuals constituting the lowest level and the upper levels being formed by application of comprehension operations to the entities lying at prior levels.

This way of thinking of set comprehension differs radically from the way Frege thought of it. Fregean comprehension did not presume an ordering of entities according to some 'priority' ranking, and it was not restricted to collection of entities formed at prior levels. Perhaps even more importantly, it did not posit a '0th-level' domain of entities as somehow given prior to all comprehension by concepts. Indeed, in Frege's scheme, the whole idea was to avoid the need of having a 'starting' collection—particularly an infinite one—to serve as the raw material from which comprehension by concepts is to get off the ground. For, in Frege's view, having a non-conceptually comprehended domain of individuals required something like Kantian intuition, and this is exactly what he hoped to avoid (since he did not see how knowledge of such a domain could rightly be seen as *logical* knowledge).

Russell, though he showed some sensitivity to this difficulty, seems never to have settled on a means of resolving it. In his earlier writings

he sometimes spoke (cf. [2.120], section 5, ch. 1) as if any statement positing a domain of existents, and therefore any axiom positing a domain of individuals, is not to be regarded as a truth of pure mathematics *per se*, but rather as an hypothesis whose consequences are to be investigated.

Later (cf. introduction to [2.120] (2nd edn) and [2.124]), however, he stated both that he believed such a view to be mistaken and that he himself had never held such a view. There are also systematic elements of his thought that would (or at least should) have led him to reject such a view. Chief in this regard was his belief in the need for the 'regressive' method in the foundations of mathematics (defended in both [2.123] and [2.124]).

Use of the regressive method allows the truth of a principle to be inferred from its usefulness in deductively unifying a recognized body of truths. Hence, to the extent that the postulation of a domain of individuals (e.g. an axiom of infinity) has utility as a means of deductively organizing the recognized truths of mathematics, it, too, inherits a certain plausibility and so deserves to be 'detached' and asserted as a truth on its own right. Russell's 'regressive' method thus elevated axioms of existence to the status of justified assertions, and so made them more than mere 'hypotheses' to be used as antecedents of conditionals whose consequents are propositions whose proof requires their use. There would therefore seem to be a tension between Russell's adoption of the 'regressive' method in mathematics and that part of his logicism (suggested by remarks he made in the second edition of the *Principia* [2.126]) which saw axioms of existence (and, in particular, his axiom of infinity) as mere hypotheses to be put into the antecedents of conditionals.

But if there were differences between Russell and Frege regarding the nature and justification of the basic laws of mathematical thought, there was substantial agreement between them as regards the nature of mathematical inference. In particular, there was agreement on the points that the inferences of mathematics are all to be strictly logical in character, and that this is necessary in order to satisfy the demands of rigour.

It is not always easy to see the similarities between their views, however, because they used different definitions of analyticity and syntheticity. For Frege, a synthetic inference was one in which the conclusion could not be extracted from the premisses by any re-carving of their contents, but rather required something like an infusion of intuition in order to connect the conclusion with the premiss(es). For Russell, on the other hand, an inference was synthetic, and, so, epistemically productive (at least in a minimal way), if its conclusion constituted a *different proposition from* its premiss(es). Thus, many inferences that Frege would

have classified as 'analytic', would have been classified by Russell as 'synthetic'.

The standard of syntheticity in inference set forth by Russell was weaker than that set forth by Frege. Consequently, many inferences satisfying Russell's condition would not satisfy Frege's.[26] Indeed, judged by the lights of Russell's definition, even the elementary inferences of syllogistic reasoning, which Frege classified as analytic, would have been counted as synthetic by Russell. This was all to the good so far as Russell was concerned. For it enabled him to meet Kant's challenge to explain the epistemic substantiality of mathematical reasoning while at the same time maintaining, in opposition to Kant, that the inferences involved in such reasoning are of a purely formal, logical nature and make no appeal to intuition (cf. [2.121]). If growth of knowledge through inference is essentially a matter of thereby obtaining a justified judgement whose propositional content is simply *distinct* from those of one's previously justified judgements, then even very elementary logical inferences can be epistemically productive.

The 'logicization' of mathematical inference was thus, in Russell's opinion (cf. [2.120], 4), nothing to be balked at epistemically. What had kept previous generations of thinkers, and, in particular, Kant, from embracing it was simply the relatively impoverished state of logic prior to the late nineteenth century. The old logic with its meagre stock of subject-predicate forms may have been inadequate to the riches of mathematical reasoning, but the new logic with its robust functional conception of form had changed all this. With its help mathematical reasoning could finally be logicized in its entirety, and 'a final and irrevocable refutation' (Ibid.) of the Kantian doctrine that mathematical inference makes use of intuition be given.

Effectively countering Kant's intuitional conception of mathematical inference was thus an important element of both Frege's and Russell's logicist programmes. They seemed to believe that this could be accomplished simply by deriving large bodies of mathematical theorems from specified axioms by purely logical means. On reflection, however, this seems to be mistaken. Kant may well have underestimated the power of logical inference. His main point, however, was not that there are mathematical proofs that have no logical counterparts whatsoever. Rather, it was that such counterparts, even if they were to exist, would not preserve the epistemologically essential features of the mathematical proofs of which they are the 'logicized' counterparts.

Against this essentially epistemological point, detailed *tours de force* (e.g. Frege's *Grundgesetze* and Russell's *Principles of Mathematics* and *Principia Mathematica*) which locate logical counterparts for mathematical proofs on even a grand scale can have but little effect. For the claim to be met is not that there are no counterparts, but rather that they are

epistomologically inadequate substitutes for the mathematical proofs they are to replace.

In summary, let us return to our original claim that logicism in this century arose from two very different sources, to wit, the discovery of non-Euclidean geometries and the development of symbolic logic. Frege's logicism owed the bulk of both its motivation and character to the former, while that of Russell was due primarily to the latter. This is the basic reason why Frege's logicism, unlike Russell's, was able to preserve a remarkable degree of fidelity to the precepts of Kantian epistemology.

Frege did not, however, agree with Kant's idealist conception of the faculty of reason (cf. the remark quoted from [2.49], section 105, p. 14 for an expression of this). To get a realist account, though, he had to get the right sorts of objects into the picture. They had to be independent of the human mind in order to insure the objectivity of arithmetic; but they also had to be intimately related to the basic operation of the human mind in order to avoid an appeal to intuition and thus to account for the greater pervasiveness of arithmetic as over against geometry. His solution was the logical object, the ur-form of which was the class-as-concept-extension. Through its essential relation with concepts, it could be brought close to reason. But through the objectivity of concepts it could also be made objective.

Frege's idea of giving a realist rather than idealist treatment of Kant's faculty of reason foundered on Russell's paradox. Russell's reaction to his paradox was rather different. Far from causing him to give up logicism, it led him instead to seek another basis for it—a methodological basis whose chief principle was one enjoining pursuit of maximal generality in one's theorizing, including one's mathematical theorizing.[27] In the presence of his belief that mathematical claims express generalizations, this principle led him in a natural way to a logicist conception of mathematics. In the end, however, Russell's paradox proved to be nearly as great an impediment to Russell's logicism as it was to Frege's. For just as Frege was unable to find a way to fit classes that do not descend from concepts into his realist logicism of logical objects given directly to reason, so, too, was Russell unable to find a satisfactory way of justifying laws asserting the existence of such classes as genuinely logical laws.

Intuitionism

Like Frege's logicism, the intuitionism of the early part of this century was also dominated by (i) the idea that what the mind brings forth

purely of itself cannot be hidden from it; and (ii) the belief that the existence of non-Euclidean geometries reveals important epistemological differences between geometry and arithmetic. The direct predecessors of the intuitionists appear to have been Gauss and Kronecker, who interpreted the discovery of non-Euclidean geometries differently than Frege. For whereas Frege proposed a realist modification of the creation principle in order to account for the apparent differences between arithmetic and geometry brought to light by the discovery of non-Euclidean geometry, Gauss and Kronecker, and the intuitionists after them, interpreted the difference between arithmetic and geometry in the light of the creation principle (i.e. principle (i) above), of which they adopted an idealist reading.

Thus, instead of maintaining Kant's synthetic a priori conception of geometry and trying to account for the difference between geometry and arithmetic by establishing arithmetic as analytic, the early intuitionist rejected Kant's synthetic a priori conception of geometry and proposed to account for the differences between arithmetic and geometry by seeing the former as a priori and the latter as a posteriori. As Gauss and Kronecker emphasized, arithmetic is purely a product of the human intellect, whereas geometry is determined by things outside the human intellect.[28] Years later, Weyl (cf. [2.148], 22) would reiterate the same theme, remarking that 'the numbers are to a far greater measure than the objects and relations of space a free product of the human mind and therefore transparent to the mind'.

Brouwer, too, expressed similar ideas, identifying as the primary cause of the demise of intuitionism since the time of Kant (cf. [2.16]) the refutation of Kant's belief in an a priori intuition of space by the discovery of non-Euclidean geometries. At the same time, however, he advocated resolute adherence to an a priori intuition of time, and even argued that from this intuition one could recoup a system of geometric judgements via Descartes' 'arithmetization' of geometry. He considered the 'primordial intuition of time'—which he described as the falling apart of a life-moment into a part that is passing away and a part that is becoming—as the 'fundamental phenomenon of the human intellect' (Ibid., p. 127).[29] From this intuition one can pass, via a process of abstraction, to the notion of 'bare two-oneness', which Brouwer regarded as the basal concept of all of mathematics. The further recognition by the intellect of the possibility of indefinitely continuing this process then leads it through the finite ordinals, to the smallest transfinite ordinal, and finally to the intuition of the linear continuum (i.e. to that unified plurality of elements which cannot be thought of as a mere collection of units since the relations of interposition which join them is not exhausted by mere interposition of new units). In this way, Brouwer believed (Ibid., pp. 131–2), first arithmetic and then geometry (albeit only analytic geometry), via

reduction of the former to the latter through Descartes' calculus of coordinates, come to be qualified as synthetic a priori.[30]

The early intuitionists thus retained a semblance of adherence to Kant's belief in the synthetic a priority of arithmetical knowledge while denying his belief in the a priority of our knowledge of the base characteristics of visual space. They were also staunchly Kantian in their conception of mathematical inference. Poincaré and Brouwer, in particular, devoted considerable attention to this point.[31] Indeed, Poincaré, who carried on a well-known debate with Russell in the early years of this century,[32] made the role of logical inference in mathematical proof the centrepiece of his critique of logicism. So, too, in effect, did Brouwer, though his critique was aimed at the use of logical reasoning in classical mathematics generally, and not just at the logicists' programmatic demand regarding the logicization of proof.

At the heart of the view of proof that both criticized is a conception of evidence—the *classical* conception evidence—which sees it as essentially a means of determining the (classical) truth value of a proposition. On this view, evidence is a relatively 'malleable' commodity. Its effects extend to a variety of propositions other than that which forms its direct content. This comes about as a result of subjecting the content of a piece of evidence to logical analysis, which is used to extract 'new' contents from the original content. By this means, the justificatory power which the evidence provided for its content can be transferred to the analytically extracted content. Hence, one and the same piece of evidence can be used to identify the truth value of a variety of different propositions. This holds, moreover, despite the fact that there is no parallel analysis directed at the evidence itself whose purpose is to reveal a separable part of the evidence whose content is precisely the new content brought forward by means of the analysis of its content. On the classical view, then, the prepositional content of a piece of evidence can be 'detached' from that evidence itself. Applying logical analysis to that 'detached' content, one can then transfer the warrant attaching to it to any of the new propositions extracted by means of that analysis.

Both Brouwer and Poincaré reacted sharply to this view of inference. Brouwer's reaction was based on the view that mathematical knowledge is essentially a product of introspective experience (cf. [2.17], 488). The extension or development of such knowledge can therefore not proceed via logical extrapolation of its content, since such extrapolation does not guarantee any similar extension of the experience having the extrapolated content as its content. Extension of genuinely mathematical knowledge thus requires the extension of the mathematical experience serving as the evidence for a given content into a mathematical experience of another content. (Here, experience is understood in such a way as to make it

capable of serving as the evidence for a given content only if it itself has that content as its content.) In other words, inference is not to be seen as a matter of logically extracting new contents from old and thence transferring warrant from old to new. Rather, it is to be seen as a process of *experientally transforming* an introspective construction having one content into an introspective construction having another.

Brouwer thus held that one can never 'deduce a *mathematical* state of things' (cf. [2.18], 524, emphasis mine) by means of *logical inference*.[33] He memorialized this view in his so-called *First Act of Intuitionism*, in which it he declared that mathematics should be completely separated from 'mathematical language and hence from the phenomena of language described by theoretical logic, recognizing that intuitionist mathematics is an essentially languageless activity of the mind having its origin in the perception of a move of time' (cf. [2.21], 4).

Brouwer thus adhered to a basically Kantian conception of mathematical reasoning according to which extension of mathematical knowledge via inference requires development of a new intuition underlying that inference. Poincaré, too, adopted such a conception of inference, though his view differed in certain respects from Brouwer's. Mathematical reasoning, as he put it (cf. [2.99], 32), has a 'kind of creative virtue' by which its conclusions go beyond its premisses in a way that the conclusions of logical inferences do not go beyond their premisses. Logical inference from a mathematically known proposition, therefore, though it may yield *some* kind of extension of that knowledge, will none the less typically not yield an extension of the genuinely mathematical knowledge thereby represented. In short, in order for mathematical knowledge that **p** to be extended to mathematical knowledge that q, it is not enough that **p** be seen logically to imply **q**. Rather, **p** must be seen both to be mathematically different from **q** and to *mathematically* imply **q** (cf. [2.101], bk. II, ch. 2, section 6; [2.100], ch. 1, section 5). In other words, the 'movement' from premiss to conclusion in a mathematical inference is a case of joint comprehension of the premisses and conclusion by a common mathematical 'universal' which is seen to persist in the 'differences' through which it 'moves'.

For Poincaré, then, mathematical reasoning consisted in the synthesis of different propositions by a single, distinctively mathematical structure or architecture. Thus, as with Brouwer, so, too, with Poincaré, we find a view of mathematical reasoning which contrasts sharply with the logicists' conception of mathematical reasoning.

The views of mathematical reasoning or inference of Brouwer and Poincaré are thus Kantian in the sense that they reject the idea that genuine mathematical inference can be logical. They also represent a modification of Kant's views, however. For Kant suggested (cf. [2.86],

741–6) that by means of genuinely mathematical reasoning from a given set of premisses, one can obtain conclusions that are actually *unattainable* by means of purely logical (i.e. purely analytical or discursive) reasoning from those same premisses. Such an idea, however, seems not to have figured at all in the arguments of Poincaré and Brouwer.[34] What they were stressing was a difference in *epistemic quality* between logical and mathematical reasoning—a difference which, in their view, would persist even if the two types of reasoning might prove to be result-wise equivalent. This emphasis on epistemic quality was based on their belief in a difference between the epistemic condition of one whose reasoning is founded on topic-neutral steps of logical inference and one whose inference rests on topic-specific insights into the given mathematical subject at hand. Reasoning of the latter sort presupposes a knowledge of the local 'architecture' of a subject. Reasoning of the former sort does not. To use Poincaré's own figures of speech, the difference is (i) like that between a writer who has only a knowledge of grammar versus one who also has an idea for a story (cf. [2.101], bk. II, ch. 2); or (ii) like that between a chess player who has knowledge only of the permissible moves of the several players versus one who has a tactical understanding of the game as well ([2.100], pt. I, ch. 1, section V).

The intuitionists were thus at odds with the logicists over the question of the nature of mathematical reasoning. The heart of their disagreement, moreover, was not a dispute concerning which logic is the right logic, but rather a deeper difference regarding the role that *any* logical inference—classical or non-classical—has to play in mathematical reasoning. They were, in other words, divided over the Kantian question of whether intuition has an indispensable role to play in mathematical inference. The intuitionists sided with Kant in holding that it does. The logicists took the contrary view.[35]

In the intuitionism of Brouwer, Poincaré and Weyl we thus find an attempt to work out a modified form of Kant's specifically mathematical epistemology. So far, the modifications noted include (i) the jettisoning of Kant's use of spatial intuition as a fundament for mathematical knowledge; and (ii) the extension and elaboration of his use of temporal intuition as a basis for arithmetic (and, relatedly, the reduction of geometry to arithmetic via appeal to Descartes' 'arithmetization' of geometry).

There is, however, one final modification to be noted, and that concerns the intuitionists' (in particular, Brouwer's and Weyl's) conception of existence claims. It is perhaps the most significant of all the modifications made and consists in a shift from Kant's conception of existence claims and our knowledge of them to a conception of existence claims that is more like that found in such post-Kantian romantic

idealists as Fichte, Schelling and Goethe. The basic non-Kantian element of this view was the introduction of a non-sensory, purely intellectual form of intuition *(intellektuelle Anschauung)*.[36] This was conceived as a form of self-knowledge whose key epistemic feature was its immediacy—an immediacy expressing the romantic idealists' concern with the epistemic effects of representation. They saw representation as the basic source of error and uncertainty in cognition and therefore advocated its avoidance.

Their reasoning was basically Kantian. That is, they began with the Kantian premiss that no idea or concept (more generally, no representation) contains the being or existence of that which it represents[37] and concluded from this that no concept or idea (more generally, no representation) could, in and of itself, give the existence of anything falling under it. Indeed, representations only tend to increase the epistemic distance between the knower and the object to be known since they leave the being of the object still to be given while adding grasp of the representation to those things that must be accomplished before the object can be known.

What was wanted, therefore, was some kind of representationless knowledge of being. For the paradigm case of such knowledge, the romantic idealists turned to our knowledge of our willing and acting selves. Their model for knowledge of existence thus became one of self-knowledge; in order to know that something exists, the knower must *live* it or *be* it. In other words, she must incorporate it into herself so that her knowledge of its existence becomes that of her knowledge of her own existence. As Schelling said (cf. [2.12], 344), 'the proposition that there are things external to us will only be certain… to the extent that it is identical with the proposition I exist, and its certainty can only match that of the proposition from which it derives.'

Brouwer, it seems, adopted this romantic idealist conception of knowledge of existence. His so-called *First Act of Intuitionism* can indeed be seen as issuing a call for the mathematical knower to turn into himself and to shun the epistemic indirection of the classical view of mathematics with its involvement in the representation of mathematical thought—that is, mathematical *language*.[38] Thus he reminded us:

> you know that very meaningful phrase 'turn into yourself'. There seems to be a kind of attention which centres round yourself and which to some extent is within your power. What this Self is we cannot further say; we cannot even reason about it, since—as we know—all speaking and reasoning is an attention at a great distance from the Self; we cannot even get near it by reasoning or words, but only by 'turning into the Self' as it is given to us….

> Now you will recognize your Free Will, in so far [as] it is free to withdraw from the world of causality and then to remain free only then obtaining a definite Direction which it will follow freely, reversibly.
>
> ([2.14], 2 square brackets, mine)

Here we clearly see the romanticist idea that representation impedes knowledge—an idea that was expressed in strikingly similar terms by Fichte, who said:

> Look into yourself. Turn away from everything that surrounds you and towards your inner life. This is the first demand that philosophy makes on its followers. What matters is not what is outside you, but only what comes from within yourself.
>
> ([2.41], 422)

Though we lack the space adequately to argue for it here, we believe that Brouwer adhered to this romantic idealist conception of knowledge in his mathematical epistemology. He believed that mathematical existence consisted in construction, that construction was a kind of autonomous 'interior' activity[39] and that mathematical knowledge was therefore ultimately a form of self-knowledge. The key point was summed up well in Weyl's remark (quoted earlier) that arithmetic is a free creation of the human mind and therefore especially transparent to it.

For Brouwer, then, existence claims were to be backed by exhibitions of objects (of the type claimed to exist), where these exhibitions were, at bottom, acts of *creation* by the mathematical subject. He thus departed from Kant's receptive conception of our knowledge of existence claims whose main idea was that judgements of existence must be forced upon a passive cognitive agent and not be the product of its own creative or inventive activity.[40]

Hilbert's position

In the third major 'ism' of the early period, Hilbert's so-called formalism, we find another form of Kantianism, and one which contrasts with the intuitionist position in at least three important respects. The first concerns the conception of our knowledge of existence claims that was adopted. The second concerns the epistemic importance placed on spatial or quasi-spatial intuition in the foundations of mathematics. The third concerns the distinction between genuine judgements and regulative ideals that figured so prominently in Kant's general epistemology.

As was noted above, Brouwer and Weyl conceived of the act of exhibition required for knowledge of an existence claim as, ultimately, an act of creation by the exhibiting subject. The epistemic significance of this act was taken to be based on the special access that a creating subject is supposed to have to his creations. This reduced the epistemic distance between the exhibitor and the exhibited object to that between the willing, acting subject and himself—a distance which, according to romantic idealist lights, is the desirable, optimal or perhaps only tolerable distance to have separating the mathematical knower from the objects of her existential judgements. It also, however, created an irreducible asymmetry between the exhibiting agent and all other agents as regards their knowledge of the exhibited object. Indeed, that was an essential part of the intuitionists' point—namely, that mathematical knowledge is ultimately a form of self-knowledge, and that it is indeed only self-knowledge that possesses the epistemic qualities that we want mathematical knowledge to have.

Hilbert consciously adopted a conception of mathematical knowledge that was more in keeping with what he thought of as the ideal of *objectivity*. He rejected the intuitionists' focus on the inner life and self-knowledge as too subjective a basis on which to found mathematical knowledge. In opposition to the epistemic *individualism* of the intuitionists, Hilbert opted for a more *communitarian* conception of knowledge. Indeed, he believed that it was the very 'task of science to liberate us from arbitrariness, sentiment and habit and to protect us from the subjectivism that already made itself felt in Kronecker's views and…find its culmination in intuitionism' (cf. [2.77], 475).

In Hilbert's view, therefore, there was to be a public domain of objects to which all members of the human (or at least the human-scientific) epistemic community were to have equal access. Hilbert thus stressed the fact that the objects of finitary intuitions were to be *recognizable* (wiedererkennbar) (cf. [2.75], 171). This meant that those intuitions could be re-enacted and confirmed by other intuitions, including other intuitions of the exhibitor's as well as intuitions of non-exhibitors. Consequently, the exhibitor of a finitary object would have no essential epistemic advantage over the non-exhibitor as regards knowledge of the object exhibited.

In Hilbert's finitism, therefore, the 'constructivist' demand that objects claimed to exist be exhibited was to serve the role of taking the object of exhibition out of the exhibitor's head and putting it in the public domain where both exhibitor and non-exhibitor, alike and equally, would be able (and, indeed, required) to judge the object by its intersubjectively confirmable effects. Intuitionistic and finitistic exhibition were thus two very different things. For while the whole intent of the former was to tap the epistemic power of the supposedly

special relation of intimacy that a creative subject was believed to have with respect to his own creative acts and intentions, the latter was intended to function as part of a more communitarian scheme of knowledge—a scheme in which the exhibitor had no epistemic advantage over the non-exhibitor. This parity between exhibitor and non-exhibitor is the kind of thing that is necessary if there is to be meaningful epistemic co-operation (e.g. division of epistemic labour) between them and if there is to be a way of monitoring the quality of each contributor's contribution. Epistemic co-operation, in turn, is desirable because through it the total amount of knowledge at the disposal of the individual community member can be expected to exceed that obtainable by that member himself, acting exclusively on his own.[41]

There are, then, we believe, large and important differences between the finitist and intuitionist conceptions of what is to be accomplished through exhibition. So much so, indeed, that we doubt there is much to be accomplished by describing them both as having adhered to a 'constructivist' conception of existence claims.

The second point of contrast between Hilbert and the early constructivists (which, like the preceding one, we can only mention and not develop here) concerns the very different roles they accorded to spatial intuition. Contrary to both the early constructivists (in particular, Kronecker, Brouwer and Weyl) and Kant, all of whom limited spatial intuition to geometry, Hilbert identified a type of spatial intuition which he took to be the basis of *arithmetical* knowledge. This was the position of his so-called 'finitary standpoint' according to which the basis of our arithmetical (and perhaps also our geometrical)[42] knowledge is a kind of a priori intuition in which the shapes or forms *(Gestalten)* of concrete signs are 'intuitively present as immediate experience prior to all thought' (cf. [2.75], 171; [2.76], 376; [2.77], 464) and 'immediately given intuitively, together with the objects, as something that neither can be reduced to anything else nor requires reduction' (cf. [2.76], 376; [2.77], 465).[43]

Hilbert thus proposed replacing Kant's a priori intuitions of space and time, which he viewed as so much 'anthropological garbage' (cf. [2.78], 385), with a single intuition which was taken to provide a framework of shapes or forms in which our experience of concrete signs was embedded (cf. [2.75], 171). This intuition, being 'prior to' all thought as its 'irremissible pre-condition' (cf. [2.76], 376; [2.78], 383, 385), was the source of all our a priori knowledge.

The third main point at which Hilbert's Kantianism contrasted with that of the early constructivists was in its use of certain key elements of Kant's general (as opposed to his specifically mathematical) epistemology. Of particular importance here is Kant's distinction

between genuine judgements and regulative ideals. Hilbert took this distinction as the basic model for his division of classical mathematics into a *real* and an *ideal* part. The real propositions and proofs were taken to be the genuine judgements and evidence of which our knowledge is constituted. Ideal propositions, on the other hand, though they served to stimulate and guide the growth of our knowledge, were none the less not considered to be a part of it. They did not describe things that are 'present in the world' (cf. [2.75], 190). Nor were they 'admissible as a foundation of that part of our thought having to do with the understanding *(in unserem verstandesmäßtigen Denken)*' (cf. [2.75], 190). They corresponded instead to *ideas* 'if, following Kant's terminology, one understands as an idea a concept of reason which transcends all experience and by means of which the concrete is to be completed into a totality' (Ibid.).

Hilbert's ideal sentences are therefore not to be likened to the indirectly verifiable 'theoretical sentences' of a realistically interpreted scientific theory familiar to us from logical empiricist epistemology. Rather, they are to be interpreted instrumentalistically, as having the same general regulative function as Kantian ideas of reason. The objects and states of affairs described in the 'theoretical sentences' of a realistically interpreted science clearly do not 'transcend all experience'. Kant's ideas of reason, on the other hand, do.

Hilbert's ideal propositions thus function as regulative devices. They do not 'prescribe any law for objects, and [do] not contain any general ground of the possibility of knowing or of determining objects as such' ([2.86], 362, square brackets mine). Rather, they are 'merely subjective law(s) for the orderly management of the possessions of our understanding, that by comparison of its concepts it may reduce them to the smallest number' (Ibid.).

Hilbert also followed Kant in maintaining that the use of ideal methods should be *epistemically conservative*. They should, that is, be only more efficient means of producing real judgements which could, none the less, in principle (though less efficiently) be developed through the exclusive use of real methods. As Kant put it:

> Although we must say of the transcendental concepts of reason that they are only ideas, this is not by any means to be taken as signifying that they are superfluous or void. For even if they cannot determine any object, they may yet, in a fundamental and unobserved fashion, be of service to the understanding as a canon for its extended and consistent employment. The understanding does not thereby obtain more knowledge of any object than it would have by its own concepts, but for the

> acquiring of such knowledge it receives better and more extensive guidance.
>
> ([2.86], 385)

Similarly in Hilbert. Ideal methods, he said, play an 'indispensable' and 'well-justified' role 'in our *thinking*' (cf. [2.76], 372, emphasis Hilbert's). They should not, however, be permitted to generate any real result that does not agree with the dictates of real evidence itself (cf.[2.76], 376; [2.77], 471). Their role is rather that of enabling us to retain in our reasoning those patterns of inference in terms of which we most readily and efficiently conduct our inferential affairs (cf.[2.76], 379; [2.77], 476).

These patterns are the patterns of classical logic. Thus, Hilbert's introduction of the so-called ideal elements was ultimately for the sake of preserving classical logic as the logic of our mathematical reasoning. Introduction of ideal methods was made necessary by the fact that there exist certain real propositions (referred to by Hilbert as *problematic* real propositions) that do not abide by the principles of classical logic. By this it is meant that when these propositions are manipulated by the principles of classical logic, they produce conclusions that are not real propositions.[44] In order to obtain, then, a system that both contains the real truths and also has classical logic as its logic, Hilbert believed it necessary to add the *ideal* propositions. He also believed this to be the minimal modification of real mathematics necessary to restore it to its epistemically optimal classical logical state (cf.[2.76], 376–9; [2.77], 469–71).

However, in thus restoring mathematical reasoning to its classical logical state, Hilbert observed that the logical operators were no longer being conceived of and employed in a semantical or contentual way as expressions for operations on meaningful propositions. Rather, they were being used in a purely syntactical way as part of a larger computationo-algebraic device for manipulating formulas. As he put it:

> we have introduced the ideal propositions to ensure that the customary laws of logic again hold one and all. But since the ideal propositions, namely, the formulas, insofar as they do not express finitary assertions, do not mean anything in themselves, the logical operations cannot be applied to them in a contentual way, as they are to the finitary propositions. Hence, it is necessary to formalize the logical operations and also the mathematical proofs themselves; this requires a transcription of the logical relations into formulas, so that to the mathematical signs we must still adjoin some logical signs, say
>
> | & | ∨ | → | ~ |
> |---|---|---|---|
> | and | or | implies | not |
>
> ([2.76], 381)

We thus find here a final step of abstraction from meaning in Hilbert's ideal mathematics—namely, abstraction from the meanings of the logical constants. It was made necessary by the decision to preserve the psychologically natural laws of classical logic as the laws of mathematical reasoning; a decision which, in turn, was the result of trying to preserve the most effective 'canon' available to us for the development of our real mathematical judgements. Ultimately, then, this 'formalism' of Hilbert's, with its radical abstraction from meaning, derived from his Kantian conception of the distinction between the real and ideal propositions according to which he saw the cognitive or epistemic value of the ideal elements as residing in their utility as instruments for extending our real judgements.

At the same time, however, it is also almost certainly this same radical abstraction from meaning that has tempted so many to misdescribe Hilbert's position as a *formalist* position in the sense of one which sees mathematics as a 'game' played with symbols. The idea behind this 'game' imagery, presumably, is that when every trace of meaning is obliterated, as in Hilbert's view of ideal mathematics, mathematics becomes ultimately a symbol-manipulation activity conducted according to certain rules; rules which, moreover, answer not to anything as serious as a concern for objective truth, but rather only to such less weighty concerns as a subjective or psychological urge for logical unity in our thinking. Even such a well-positioned and astute interpreter of Hilbert as Weyl eventually succumbed to the temptations of this description of Hilbert's views (cf.[2.147], 640). In our opinion, however, such an interpretation fails to take account both of Hilbert's overall Kantian epistemology and of certain quite specific remarks he himself made regarding the syntactical character of ideal reasoning. Hence, while we see no particular reason to deny the title of formalism to Hilbert's position, we would none the less insist that it is formalism of a quite different kind than the 'game-played-with-symbols' formalism. Hilbert stated his view forcefully in the following remark.

> The formula game that Brouwer so deprecates has, besides its mathematical value, an important general philosophical significance. For this formula game is carried out according to certain definite rules, in which the *technique of our thinking* is expressed. These rules form a closed system that can be discovered and definitively stated. The fundamental idea of my proof theory is none other than to describe the activity of our understanding, to make a protocol of the rules according to which our thinking actually proceeds. Thinking, it so happens, parallels speaking and writing: we form statements and place

> them one behind another. If any totality of observations and phenomena deserve to be made the object of a serious and thorough investigation, it is this one.
>
> ([2.77], 475 (emphasis Hilbert's))

This suggests that the rules of the so-called 'game' of ideal reasoning are nothing other than the basic laws of human thought. The heart of Hilbert's proof theory, and the heart of the 'formalism' of his later thought, was thus the belief that much of human mathematical thought is, at bottom, formal-algebraic or syntactical in character. Indeed, as he remarked elsewhere, the custom in mathematical thought, and in scientific thought generally, is to make 'application of formal thought-processes *(formaler Denkprozesse)* and abstract methods' (cf.[2.78], 380). In fact, he noted,

> Even in everyday life one uses methods and conceptual constructions which require a high degree of abstraction and which only become intelligible by means of an unconscious application of the axiomatic method. Examples are the general process of negation and the concept of infinity.
>
> (Ibid.)

What emerges from all this is an idealistically oriented formalism whose goal is to locate and defend (as a sound regulative device) the basic 'forms' of human thought. These forms of thought, which might be thought of as *theory-forms*, represent high-level commonalities of form that our thinking about a wide variety of subjects share. It is less clear whether, in speaking of 'the techniques of our thinking' as being expressible in a 'closed system' of rules that can 'be discovered and definitively stated' ([2.77], 475), Hilbert meant a single system of rules which gives a general algebra of thought, or whether he was thinking of a plurality of different theory-forms, the repository of which is classical mathematics. In either case, however, we obtain a formalism whose forms are fundamentally forms of *thought*—forms of thought, moreover, which, despite their syntactical character, are none the less deep expressions of the nature of human reasoning and therefore much more than a mere 'playing' of a 'game' with symbols.

For Hilbert, then, the ideal methods of thinking constituted a logical mould to whose contours our minds are shaped in their inferential dealings. This makes their use inviting, if not unavoidable. But inviting or not, the legitimacy of ideal reasoning still depends on the satisfaction of a certain condition—namely, its consistency, or, more specifically, its *finitarily demonstrable consistency with the finitarily provable propositions*.[45] As is well known, however, it is precisely the satisfaction of this requirement

that was called into question by Gödel's discovery of his celebrated incompleteness theorems in 1931 (cf. [2.62]).

The proofs of these theorems featured a technique (commonly referred to as the 'arithmetization' of metamathematics) for representing the concepts and statements of the metamathematics of a given formal system **T**[46] in that portion of a formal theory of arithmetic that contains the elementary theory of recursive operations on the natural numbers. For present purposes, the important feature of this fragment of arithmetic is that it appears to be contained in what Hilbert regarded as the *finitary* part of number theory. For that reason, it also appears to be contained in those ideal theories of classical mathematics which it was Hilbert's concern to defend as legitimate.

What Gödel was able to show was first that for any formal system **T** containing the elementary fragment of arithmetic spoken of above, if **T** is consistent, then there is a sentence *G* of the language of **T** such that neither *G* nor ¬ *G* is a theorem of **T**. Using the proof of this *first incompleteness theorem*, Gödel was then able to prove a *second incompleteness theorem* by formulating in **T** a sentence, Con_T, of which there is reason to say that it expresses the claim that **T** is consistent, and of which it can be proven that it is not provable in **T** if **T** is consistent. From this second theorem, and the assumption that **T** contains finitary arithmetic, it is then concluded that the consistency of **T** is not provable by finitary means. From this conclusion it is in turn inferred that no system **I** of ideal mathematics that contains **T** is such that its real-consistency can be proven by finitary means, and from this, finally, it is concluded that Hilbert's intended defence of the ideal reasoning of classical mathematics cannot be carried out.

In the beginning, Gödel shied away from this conclusion, maintaining (with characteristic caution) that his second theorem did 'not contradict Hilbert's formalistic viewpoint' since 'it is conceivable that there exist finitary proofs that *cannot* be expressed' in the classical systems for which that theorem had been proved to hold (cf. [2.62], 615). Eventually, however, he was persuaded by Bernays that these reservations were unwarranted, at which time he then accepted the view that his second theorem did indeed refute Hilbert's programme as it was originally conceived by Hilbert (cf. [2.64], 133).

THE LATER PERIOD

This completes our discussion of the developments of the early period. We turn now to the later period (i.e. the period after 1931), where we shall begin by considering the changes it brought to the 'isms' of the early period.

Hilbert's Formalism

The above-stated argument against Hilbert's programme using Gödel's theorems gained nearly universal acceptance in the later period and has indeed become a commonplace amongst twentieth-century philosophers of mathematics. The few challenges there have been to it have been mainly of two types: (i) those that seek to revive Hilbert's programme by arguing for a less restrictive conception of fmitary evidence (and, hence, a more potent base from which to launch the search for a finitary proof of the real-consistency of ideal mathematics) than was originally intended by Hilbert; and (ii) those that seek a more restricted body of ideal methods whose real-consistency needs to be proven.

Those belonging to the first camp (e.g. Gentzen [2.61], Bernays [2.8], Ackermann [2.1], Gödel [2.64], Kreisel [2.90], Schütte [2.128], Feferman [2.38]; [2.39] and Takeuti [2.138]), in one way or another have all argued that the means used in giving the proof of real-consistency required by Hilbert's programme ought to be extended to means reaching beyond that which is formalizable in what has commonly been recognized as the natural formalization of Hilbert's finitary standpoint (namely, the theory known as *Primitive Recursive Arithmetic,* or **PRA**).[47] Among those, some (e.g. Gentzen [2.61], Ackermann [2.1], and, on one reading, Gödel [2.64]) have questioned the correctness of identifying the finitary with what is formalizable in **PRA,** arguing that finitary reasoning extends well beyond that which is formalizable in **PRA,** and includes such things as forms of transfinite induction which go beyond even what is provable in ordinary first-order Peano arithmetic **(PA)**.

The basic idea of this line of thought is that there are types of reasoning which (a) are not codifiable in **PRA,** but which none the less (b) share the same characteristics believed to give finitary evidence its distinctive epistemological credentials, and which (c) allow us to establish the consistency of much of the ideal reasoning of classical mathematics that cannot be secured by means of proofs formalizable in **PRA**. It is therefore argued that an extension of what is to be counted as admissible reasoning in constructing the required consistency proofs of the various ideal systems of classical mathematics is in order, and that a significant partial realization of Hilbert's original aims can thus be attained.

Others (e.g. Kreisel [2.90] and Feferman [2.39]) in the first camp have argued not so much for a reconsideration of what should be counted as finitary evidence, as for a liberalization and refinement of what are the epistemically gainful means of proving consistency, whether or not they are properly classifiable as finitary. The basic idea here is that the simple distinction between real and ideal methods does not begin to do justice to

the rich scheme of gradations in epistemic quality that separate the various kinds of evidence available for use in metamathematical proofs. Hence, this simple distinction should be replaced by a more refined scheme which distinguishes not only the finitary and the non-finitary, but also the various 'grades' of both constructive and non-constructive methods (and the various reducibility relations which exist between the distinguished kinds of non-constructive methods and the distinguished kinds of constructive methods).[48] When this is done, it is claimed, results amounting to a substantial partial realization of a generalized Hilbert's programme can be achieved (cf. Kreisel [2.90] and Feferman [2.39]).

The same basic conclusion is arrived at by a quite different line of reasoning in the so-called programme of 'reverse mathematics' of Friedman and Simpson (cf. [2.134]). The strategic idea of this programme is basically the opposite of that of Kreisel and Feferman. It does not aim at *beefing up* the methods available for constructing the requisite consistency proofs, but rather at *cutting down* the systems of ideal reasoning whose consistency needs proving. This is to be done by giving a more exact characterization of the core of ideal reasoning that is truly indispensable to the reconstruction of the essential results of classical mathematics.

The reverse-mathematical revision of Hilbert's programme thus begins by isolating those results of classical mathematics that are believed to constitute its 'core'. It then seeks to find the weakest possible natural axiomatic theory capable of formalizing this core. The hope is that this minimal system will eliminate unnecessary strength present in the usual axiomatizations of the core (generally, some version of second-order arithmetic) and therefore that its real-consistency will prove to be more susceptible to finitary proof than that of the usual systems.

So far, significant partial progress along these lines has been achieved. In particular, it has been shown that (i) there is a certain subsystem (known as $\mathbf{WKL}_0$) of $\mathbf{PA}^2$ (i.e. second-order Peano arithmetic) which embodies a substantial portion of classical mathematics; (ii) all the Π_1 theorems (i.e. theorems equivalent to some formula of the form where is a recursive formula) of $\mathbf{WKL}_0$ are provable in **PRA** (cf. [2.133], [2.134]; and (iii) the proof of (ii) can itself be given in **PRA** (cf. [2.132].[49] Assuming the codifiability of finitary reasoning in **PRA** and the importance of the Π_1 class of real truths, this amounts to a finitary proof of the real-consistency of an important part of classical ideal mathematics. This, in turn, would constitute a significant partial realization of Hilbert's programme.

In addition to these two alternatives, it is possible to describe, at least in philosophical outline, a third approach which seems in certain

important respects to be closer to Hilbert's original ideas than either of them. The key element of this third alternative, which is absent from each of the other two approaches just described, takes its lead from the Kantian character of Hilbert's conception of ideal mathematics. In particular, it stresses the point that Hilbert's ideal methods, like Kant's ideas of pure reason, are recommended solely by the efficiency that their instrumental use is supposed to bring to the development of our real judgements.

This means, among other things, that ideal propositions and inferences that fail to bring with them discernible improvements in efficiency (when compared to their real counterparts proving the same results) do not belong to that part of ideal mathematics that need, in principle, be defended by Hilbert. In other words, ideal elements that fail in any significant way to increase the efficiency of the development of our real knowledge have, in principle, no claim to be included among those ideal elements whose real-consistency the Hilbertian must defend. Therefore, in identifying the elements (i.e. axioms and rules of inference) of an ideal system I for whose defence the Hilbertian is to be held accountable, it must be borne in mind that they must figure in some significant way in the production of efficiency; that is, each must be an essential ingredient in some ideal derivation $\mathbf{\Delta}_1$ of a real theorem τ_R such that (i) $\mathbf{\Delta}_1$ (together with the necessary metamathematical proof of soundness for $\mathbf{I}^{50}$) is more efficient than any real proof of τR, and (ii) $\mathbf{\Delta}$1 is the only derivation in **I** that significantly improves upon the efficiency of the real proofs of τ_R. If an item (e.g. an axiom, rule of inference, etc.) of **I** possesses none of the virtues of efficiency for which ideal elements are in general prized, then, in principle, it can and should be eliminated from **I**. With all such eliminations made, one would expect the prospects for a finitary proof of **I**'s consistency to have been improved. Therefore, the question of whether an ideal system is comprised wholly of elements that are essential in the above-indicated sense ought to be of prime importance in determining the make-up of those ideal theories for whose defence the Hilbertian is ultimately taken to be responsible.

Yet, despite its clear importance for the proper reckoning of the ultimate responsibilities and prospects of Hilbert's programme, this question has been either ignored or overlooked by those writing on the subject. Simpson (cf. [2.134], 360–1), for example, readily admits that the proofs of standard theorems in $\mathbf{WKL}_0$ and are sometimes 'laborious' and 'much more complicated than the standard proof(s)'. Yet he takes no notice of the potential this feature of reverse mathematics has to undo its entire rationale for effecting a partial realization of Hilbert's programme. To the extent that the proofs in $\mathbf{WKL}_0$ and $\mathbf{WKL}_{\mathring{0}}$ are *more* laborious than the 'standard' proofs of the

same ideal theorems, to the same extent are $\mathbf{WKL}_0$ and of questionable worth as models of Hilbert's ideal reasoning. Moreover, were the least laborious ideal proofs of real theorems in $\mathbf{WKL}_0$ and $\mathbf{WKL}_0^*$ to reach levels of laboriousness equal to those of the least laborious real proofs for those theorems, they would cease to be ideal proofs that the Hilbertian should want to preserve, and, hence, cease to be proofs whose soundness he should be obliged to defend.

It is thus important for the 'reverse mathematicians' to answer the following questions: (1) Do the ideal proofs of real theorems in $\mathbf{WKL}_0$ and preserve, at least on balance, the kinds of gains in efficiency for which ideal reasoning was prized by Hilbert in the first place?; and (2) Are the ideal proofs of real theorems in $\mathbf{WKL}_0$ and less laborious than their most efficient real counterparts? To the extent that either of these questions is answered in the negative, the reverse mathematicians' use of the systems of reverse mathematics to establish partial realizations of Hilbert's programme becomes implausible. So far as I can see, however, the reverse mathematicians have done nothing to allay fears that such questions as (1) and (2) above may have to be answered in the negative.

It would be unfair, however, to lay too much blame on the reverse mathematicians. For the questions they have neglected have been generally neglected by those writing on Hilbert's programme. This includes philosophers, too (indeed, perhaps primarily), and not just logicians. All have failed properly to emphasize two fundamental points: (i) that the prospects for Hilbert's programme can adequately be assessed only when a suitably accurate means of comparing the complexity of real and ideal proofs has been developed and those systems containing the gainful ideal proofs have been identified; and (ii) the complexity metric figuring in (i) is capable of measuring not only the kind of complexity (call it *verificational complexity*) that is encountered when one sets about the task of determining of a *given* item whether or not it is an ideal proof of a certain kind, but also, and, indeed, primarily, a kind of complexity (call it *inventional complexity*) which constitutes the complexity involved in *discovering* an ideal proof of the desired kind in the first place.[51] Failure to appreciate points (i) and (ii) has, it seems to me, led to inadequate attention being paid to the development of *appropriate* metrics for measuring the complexity of ideal proofs and comparing the complexity thus measured to that for the corresponding real proofs. Without the development of such a theory of complexity, however, it does not seem to me possible to render a compelling final assessment of Hilbert's programme—and by that I mean the programme of Hilbert's *original* philosophical conception.

Logicism

Logicism re-emerged in the 1930s and 1940s as the favoured philosophy of mathematics of the logical empiricists (cf. [2.22], [2.23] and [2.66]). I say 're-emerged' because the positivists did not develop a logicism of their own in the way that Dedekind, Frege and Russell did. Rather, they simply appropriated the technical work of Russell and Whitehead (*modulo* the usual reservations concerning the axioms of infinity and reducibility)[52] and attempted to embed it in an overall empiricist epistemology.

This empiricist turn was a fairly novel development in the history of logicism, and it represented a radical departure from both the original logicism of Leibniz, which was part of a larger rationalist epistemology, and the more recent logicism of Frege, which was strongly critical of empiricist attempts to accommodate mathematics (cf. Frege's criticism of Mill in [2.49], sections 9–11, 23–5). It was, perhaps, less at odds with Russell's logicism with its imputation of a common methodology linking mathematics and the empirical sciences.

Like all empiricists, the logical empiricists, too, struggled with Kant's idea that mathematics is immune to empirical revision. More accurately, they struggled with the Kantian problematic concerning how to account for the apparent certainty and necessity of mathematics while at the same time being able to explain its seeming robust informativeness.[53] Their choice of strategies for trying to accommodate these two data was to empty mathematics of all non-analytic content while, at the same time, arguing that analytic truth can be 'substantial' and non-self-evident.

The logical empiricists thus sacrificed the strict empiricist claim that all knowledge is evidensorily based on the senses. Their empiricism was, therefore, a liberal empiricism, an empiricism making use of a distinction like that of Hume's between 'relations of ideas' and 'matters of fact' (cf. [2.83], section IV, Pt. I). The exact distinction they utilized was one calling for the separation of those propositions whose truth or falsity is determined by the meanings of their constituent terms (and is therefore independent of contingent fact) and those propositions whose truth or falsity is dependent upon contingent, empirical matters of fact.[54] They then appealed to this distinction in arguing that the truths of logic are analytic in character. And from this, and the technical work of Russell and Whitehead, they concluded that the truths of mathematics are analytic.[55]

Thus, though they accepted the traditional Kantian idea that mathematical judgements are immune to empirical revision, and though they made central use of something like Kant's analytic/synthetic distinction in formulating their account of mathematics, the logical empiricists none the less rejected the distinctive thesis of Kantian

mathematical epistemology; namely, that knowledge of mathematics is synthetic a priori in character. Indeed, the denial that *any* knowledge is synthetic a priori in character was a central ingredient of the logical empiricists' epistemological outlook.

Their mathematical epistemology came under heavy attack by Quine in the 1950s. Quine's attack was based on a criticism of the pivotal distinction of the empiricists between analytic and synthetic truths (cf. [2.109], [2.111]). According to Quine, the basic unit of knowledge or judgement—the basic item of our thinking that is tested against experience—is science as a whole. Since mathematical and logical statements are inextricably interwoven parts of the larger body of science, they therefore too, at least to some extent, must derive their confirmation or disconfirmation from empirical sources. Consequently, the statements of logic and mathematics cannot rightly be regarded as true by virtue of meanings alone, if by that there is intended some contrast with statements regarded as true in virtue of the facts. A distinction between truths of meaning (i.e. analytic truths) and truths of fact (i.e. synthetic truths) cannot therefore be maintained. Yet, without some such distinction, the logicism of the logical empiricists does not have a hope of succeeding.

Within a relatively brief period of time, this critique of Quine's became a major influence in the philosophy of mathematics and, under the weight of that influence, the logicism of the logical empiricists began to sink into oblivion. There have, however, been a few attempts to revive (or, perhaps better, to exhume) logicism along other lines. The most systematic and detailed (if, perhaps, not the most convincing) of these is that given in the two-volume work of David Bostock (viz. [2.12]). This is not, however, so much a defence of logicism as it is an attempt to determine a best case for it, so that its plausibility as a philosophy of arithmetic might finally be judged.[56] Indeed, he ends up concluding that logicism is of strictly limited viability as a philosophy of arithmetic. The main point of his argument is that there is no unique reduction of arithmetic to logic, and that this creates problems for any logicism (like, say, that of Frege or Russell) that wants to identify numbers with *objects*.

More nearly defences are the recent attempts by Hilary Putnam, Harold Hodes, Hartry Field and Steven Wagner to establish the plausibility of modified forms of logicism. Putnam [2.102] and Hodes [2.81] both offer defences of a type of logicist position also known as 'ifthenism' or 'deductivism'.[57] The former argues that, though statements of existence in mathematics are generally to be seen as statements asserting the existence of structures, they are not to be taken as assertions of the actual existence of these structures, but only of their possible existence. Existence statements are therefore, at bottom, logical claims,

and they are to be verified by generally logical means (and, in particular, by syntactical consistency proofs).

Hodes takes a somewhat different approach, arguing, in a manner reminiscent of Frege, that arithmetic claims can be translated into a second-order logic in which the second-order variables range over functions and concepts (as opposed to objects). In this way, commitment to sets and other specifically mathematical objects can be eliminated, and, this done, arithmetic may be considered a part of logic.

Field (cf. [2.42], [2.43]) offers what might be regarded as an epistemological form of logicism. He is concerned to defend the claim that mathematical knowledge is (at least largely) logical knowledge. He also argues, contrary to Quine and Putnam (see below), that one can be a realist with respect to physical theory without being a realist with respect to mathematics.[58]

Field begins his argument that mathematical knowledge is logical knowledge by defining mathematical knowledge as that knowledge which 'separates a person who knows a lot of mathematics from a person who knows only a little mathematics' (cf. 2.43], 511, 544). He then goes on to claim that what separates these two kinds of knowers is '*not* that the former knows many and the latter knows few' (cf. [Ibid], 511–12; 544–5) of such claims as those for which mathematicians commonly provide proofs of (i.e., of those claims, such that there are prime numbers greater than a million). Rather, he goes on to say, 'insofar as what separates them is knowledge at all, it is knowledge of various different sorts' (Ibid.).

Some of it is empirical knowledge (e.g. knowledge of what is commonly accepted by mathematicians and what they regard as the proper starting point for an inquiry). The bulk, however, is knowledge 'of a purely logical sort—even on the Kantian criterion of logic according to which logic can make no existential commitments' (Ibid., 512). In the end, Field concludes, mathematical knowledge for the most part comes down to knowledge that certain sentences do and certain other sentences do not follow from a given set of axioms.

Generally, such knowledge would either be understood in a semantical way (as knowledge about a class of models) or in a syntactical way (as knowledge about a class of formal proofs or derivations). Neither of these, however, qualifies as logical knowledge in the sense Field wants. For since models are just a particular kind of mathematical object, knowledge of them must be just a particular kind of mathematical knowledge. Similarly for syntactical derivations. For whether they are conceived of abstractly or concretely, they cannot be known to exist on purely logical grounds, since (so the reasoning goes) pure logic cannot assert the existence of things.

Field is therefore obliged to offer an account of logical knowledge that frees it of the need to be knowledge of semantical or syntactical entities. What he comes up with is a kind of 'modal' analysis according to which knowledge that a given sentence S follows from a given set of sentences A is (i) knowledge that **N** (A→S) (where '**Nϕ**' is to be read as 'it is logically necessary that ϕ'), and knowledge that S does not follow from A is (ii) knowledge that **M**(A&¬S) (where '**Mϕ**' is to be read as 'it is logically possible that ϕ'). The key feature of this analysis is that it treats the sentences 'A' and 'S' as *used* rather than *mentioned*. Hence, it treats **'N'** and **'M'** as operators (indeed, logical operators) rather than predicates that apply to entities like models, possible worlds and/or proofs.

Field identifies the chief task facing this analysis as that of accounting for the applicability of mathematics to physics, and he divides this task into two sub-tasks: namely: (a) that of showing the mathematics applied to be 'mathematically good'; and (b) that of showing that the physical world is such as to make the mathematical theory particularly useful in describing it. Both tasks must be carried out without appeal to the truth of (any parts of) mathematics if Field's logicist ideal is to be met, and it is to the demonstration of this that Field's writings on the subject (cf. 2.42 and 2.43) are primarily devoted.

There is much to question in Field's argument (cf. [2.130], [2.115], [2.27]; but see also Field's responses in [2.44] and [2.45]). For present purposes, however, we shall restrict ourselves to a question concerning the overall place of logical reasoning in mathematical proof. This, we noted earlier, was a point of central concern in Kant's mathematical epistemology, and was taken over as a principal motivating factor of the intuitionist epistemologies of Brouwer and Poincaré. Their belief, and the crux of their disagreement with logicism, was that mathematical and logical inference are fundamentally different—that the former is not only not reducible to the latter, but that it is indeed antithetical to it. As Poincaré put the point: mathematical reasoning has a kind of creative virtue that distinguishes it from the epistemically more 'sterile' reasoning of logic (cf. [2.99], 32–3); the logical reasoner's grasp of mathematics is like the grasp of elephanthood that naturalists would have were their knowledge to be restricted entirely to what they had observed through microscopic examination of their tissue.

> When the logician shall have broken up each demonstration into a multitude of elementary operations, all correct, he still will not possess the whole reality; this I know not what which makes the unity of the demonstration will completely escape him. In the edifices built up by our masters, of what use to admire the work of the mason if we cannot comprehend the plan of the architect? Now

> pure logic cannot give us this appreciation of the total effect; this we must ask of intuition.
>
> ([2.101], 436)

Poincaré therefore believed in a distinctively *mathematical* kind of reasoning. Without it one cannot account for the manifest differences in epistemic condition which separate the logical from the genuinely mathematical reasoner.[59] He would, therefore, have denied Field's assumed starting point that mathematical knowledge is largely logical knowledge and also his claim that the modalities pertaining to mathematical reasoning are *logical* rather than distinctively mathematical in character.[60] Both points, we believe, raise serious challenges for Field's position.

Steven Wagner ([2.145]) offers both a different conception and a different defence of logicism. He seeks to root mathematics in what he takes to be the universal needs and urges of (ideally) rational agents. His argument begins with the presumption of an idealized rational enquirer who seeks not only bodily survival but also understanding. He then goes on to say that counting is indispensable to such a being both in the sense of being partially constitutive of that person's rationality and in the sense of being necessary to his or her assimilation and processing of the elementary data of experience and thought. Nobody, he maintains, can get by without answering a host of 'How many?' questions. Thus, the rational agent must develop a system of counting.

From a system of counting there will eventually emerge a system of calculation. This is so because (i) calculation is essentially a refinement of counting (i.e. it functions to advance those cognitive and bodily ends that are served by the capacity to count); and (ii) there is a rational urge to improve those capacities that one possesses, but possesses in what is perhaps only too rudimentary a form[61].

Thus, from counting, the ideally rational agent passes to calculation. And from calculation, the argument continues, he or she will pass to something like number theory. This is due to the facts that (i) part of the urge to understand consists of an urge to unify, simplify and generalize; and (ii) efforts to unify, simplify and generalize one's system of arithmetic calculation will inevitably lead one to something like the arithmetic of the natural numbers. Therefore elementary number theory may be described as a kind of rational necessity.

As a final stage of rational development, the continued need and capacity to simplify, unify and generalize will eventually lead the ideally rational enquirer to some form of analysis and set theory. Wagner's 'second generation' logicism thus states that (i) any ideally rational enquirer will be under pressure to develop forms of arithmetic and set

theory; and that (ii) the theorems of such theories as are developed in response to this pressure will be analytic in the sense that *any rational being would have a reason to accept them*.

Wagner's position differs in significant ways from both the metaphysical logicism of Frege and the methodological logicism of Russell. It also differs from Field's logicism—particularly over the question of the in-principle dispensability of mathematics as a device for processing empirical information. Field believes that it is dispensable. Wagner, on the other hand, appeals to an alleged explanatory role that at least certain mathematical theories (e.g. elementary number theory, analysis and set theory) play, and he treats that explanatory role as part of the ultimate justification for those theories. He thus treats mathematics as ultimately indispensable for the full cognitive processing (i.e. the full explanation) of empirical information.

Intuitionism

Turning finally to post-Brouwerian intuitionism, there are two main developments to note: (i) the various attempts, initiated by Heyting's work, to formalize intuitionistic logic and mathematics and to develop it into something roughly comparable in power to classical mathematics; and (ii) the more recent attempts by Dummett and his followers to derive a philosophical justification for intuitionism from a kind of Wittgensteinian conception of the meanings of mathematical sentences.

Since (i) is only very loosely connected with philosophical concerns, we shall say little about it here. The reader desiring a relatively up-to-date presentation of technical findings may consult any of a number of recent surveys (e.g. [2.4], [2.13], or [2.143]) of the subject. We shall confine our discussion of (i) to the idea that seems to have been at the centre of Heyting's attempts to formalize intuitionistic reasoning; namely, the supposed distinction between 'a logic of existence' and 'a logic of knowledge'—a distinction Heyting regarded as fundamental to intuitionistic thought ([2.70], 107).

What Heyting meant by a 'logic of existence' is a logic of statements about objects whose existence is to be understood as being independent of human thought. Intuitionists, and other constructivists too, for the most part, reject the idea of a realm of thought-independent mathematical objects. Likewise, they reject the idea that mathematical propositions are true or false independently of human thought. They hold, instead, the view that mathematical propositions express the results of certain kinds of mental constructions.[62] A logic of such propositions—a 'logic of knowledge', in Heyting's terminology—is therefore one whose theorems express relations between mental constructions; specifically, relations of

latent containment among them (where one construction is taken latently to contain another just in case going through the process of effecting the one would automatically either effect the other or put one in a position to effect it).

Given this general outlook, Heyting argued, there is no essential difference between logical and mathematical theorems. Both serve essentially to affirm that one has succeeded in performing mental acts satisfying certain conditions. The former are distinguished only by their relatively greater generality ([2.69], 1–12; [2.70], 107–8).

Intuitionist logic was thus intended by Heyting to serve as an articulation of those most general patterns of latent containment relating our mental mathematical constructions.[63] Since, however, our mental constructional activities constitute 'a phenomenon of life, a natural activity of man' ([2.69], 9), containment relations between them are not conceptually based but rather based on the relations which bind our activities together *behaviourally*, as it were. Thus, a logical theorem to the effect that we know a proof of A only if we know a proof of B would express neither a conceptual connection between our knowledge of a proof of A and our knowledge of a proof of B, nor, except *per accidens*, a conceptual connection between A and B. Rather, it would express a natural fact concerning our (perhaps idealized) mental constructional life, namely, that it is characterized by a disposition to transform proofs of A into proofs of B. As Heyting himself put it, 'mathematics, from an intuitionistic point of view, is a study of certain functions of the human mind' ([2.69], 10). As such, it is akin to history and the social sciences (Ibid.).

Michael Dummett ([2.36], [2.37]) has offered both a different conception and a different defence of intuitionism. He conceives it as a view concerning what is to be regarded as the proper *logic* of mathematics. He argues that an adequate account of the meanings of mathematical propositions reveals that it is intuitionist logic (i.e. the logic set out by Heyting) that is the proper logic of mathematics. This account bears certain affinities to the views on meaning set out by Wittgenstein in his *Philosophical Investigations*. In particular, like Wittgenstein's view, it equates the meaning of a sentence with its canonical use. In mathematics, Dummett believes, canonical use consists in the role that an assertion plays in the central activity of proof. Hence, to know the meaning of a mathematical sentence is ultimately to know the conditions under which it would be proved or refuted.[64]

Dummett's intuitionism is thus far removed from that of Poincaré and Brouwer both in substance and motive.[65] Its defence is also, we believe, open to certain doubts. Dummett argues that since (i) 'that knowledge which, in general, constitutes, the understanding of language…must be implicit knowledge' ([2.36], 217), and (ii) 'implicit knowledge

cannot…meaningfully be ascribed to someone unless it is possible to say in what the manifestation of that knowledge consists—there must be an observable difference between the behaviour or capacities of someone who is said to have that knowledge and someone who is said to lack it' (Ibid.)—that it therefore follows that (iii) 'a grasp of the meaning of a…statement must, in general, consist of a capacity to use that statement in a certain way, or to respond in a certain way to its use by others' (Ibid.).

Premiss (ii), we believe, is inappropriate as a premiss in an argument for (iii). For it seems to beg the crucial question, namely, that concerning whether implicit knowledge (and hence knowledge of meaning) is ultimately to be taken as consisting in a capacity for behaviour or in, say, something like one's being in a mental or psychological or neural state that *underlies* such behaviour. Everyone, it would seem, must agree that (ii') implicit knowledge cannot legitimately be ascribed to someone unless such ascription is warranted by the best total explanation of his or her observed behaviour.[66] But (ii') carries with it no guarantee that, as (ii) requires, an ascription of implicit knowledge be traceable to some specific piece or pieces of speaker behaviour or, indeed, that it will even be traceable to the entire corpus of the speaker's behaviour. Speaker behaviour will, after all, typically underdetermine its best total explanation. Nor is there any reason to believe in advance that the best total explanation of the speaker's behaviour will not differ from its rivals in its ascriptions of implicit knowledge to the speaker.

Thus, to avoid begging the question, premiss (ii) of Dummett's argument would seemingly have to be replaced by something like (ii'). Such replacement, however, would block valid passage to (iii), and (iii) is at the heart of Dummett's defence of intuitionism. To salvage his defence would therefore seemingly require finding something like our (ii') that would (in the company of premiss (i), of course) validly imply (iii). It is not at all clear that this can be done, however.[67]

As noted above, Dummett's defence of intuitionism appeals to certain ideas of Wittgenstein's, or, at any rate, ideas that Dummett and others have attributed to Wittgenstein. It would, however, we believe, be a mistake to identify Wittgenstein's ideas on the philosophy of mathematics too closely with intuitionism.[68] For though it does bear affinities to those forms of constructivism which stress the autonomy of mathematics as a human creation (where creation is understood to consist ultimately of acts of will or decision), it also bears certain affinities to a more conventionalist interpretation. Moreover, in the end, it resists categorization as *either* a constructivist or a conventionalist philosophy.

Wittgenstein's central idea seems to have been that there is a basic kind of construction in mathematics known as a *Beweissystem*. A *Beweissytem* is made up of proofs and theorems, but its theorems function

as rules of logical syntax rather than descriptive truths concerning the terms of the system. These rules constitute autonomous acts of will by which are laid down the rules according to which we agree to play a certain 'language game' involving the terms introduced by the system. Mathematics as a whole, Wittgenstein maintained, is a 'motley' of such *local* activities or games.

For Wittgenstein, then, mathematical proofs (including even the simplest ones) do not play the role of *compelling* us to accept their conclusions. Nor are mathematical propositions in any other way 'forced' upon us as being true. 'Acceptance' of a mathematical statement does not therefore represent an acknowledgment of its truth, but rather represents a *decision* on our part to count something as a convention of a certain language game. Similarly, proof does not function to *remove* doubt through penetration of the truth, but rather to *exclude* doubt as a logical possibility through the establishment of a theorem as a *norm* governing a certain language game.

Thus, though Wittgenstein saw mathematics as essentially a human creation, he did not understand this in the *descriptive* way that constructivists traditionally have understood it. Nor did his normative conception of our mathematical creations lend itself to any of the usual conventionalist interpretations. For those all call for the reduction of mathematical truths to logical truths and this requires the 'co-operation' of the logical forms of mathematical truths, so to speak (since there are logical forms that a statement might have that would prohibit it from being reducible to a logical truth).

Logical form does not, however, appear to form the same kind of constraint on the institution of norms or rules. Moreover, even if it did, there is a big difference between a statement's being a logical truth and its being a norm of logical syntax. The former has to do with whether a statement passes a certain test of truth invariance (i.e. that it be stable under a certain variety of different semantical interpretations of its semantically variable parts), while the latter has to do with whether something is to be seen as one of the *rules* constituting a certain *rule-governed activity*. Sentences failing the requisite tests of the truth-invariance test could none the less, it seems, still at least in principle play the role of rules of a linguistic game. Consequently, it seems that Wittgenstein is not well classified as a traditional conventionalist, though there is a conventionalist element in his philosophy.[69]

Later Developments

Among later developments not having primarily to do with the three 'isms', perhaps the major one is that stemming from Quine's criticism of the logical empiricists in the 1940s and 1950s mentioned above. This criticism resulted in a new empiricist philosophy of mathematics shorn of even those few Kantian ideas that were retained by the logical empiricists—and this new empiricism has been perhaps the dominant theme in the philosophy of mathematics ever since.

The logical empiricists, as was noted earlier, retained Kant's commitment to the necessity of mathematical truth (though they conceived of this necessity as essentially consisting in immunity from empirical revision). Indeed, it was precisely for the sake of accommodating this 'datum' of mathematical epistemology that the logical empiricists put so much effort into nurturing and preserving the Kantian distinction between analytic and synthetic judgements. In their view, only such a distinction could sustain the division of mathematical judgements into those that are and those that are not subject to empirical revision.

Quine (see [2.108], [2.109]) and Putnam (see [2.105], [2.106]) swept even this final Kantian datum aside, offering instead a general empiricist epistemology in which all judgements, those of mathematics and logic as well as those of the natural sciences, are seen as evidentially connected to sensory phenomena and therefore subject to empirical revision. Central to their argument was an observation borrowed from Duhem; namely, that in order to connect science with sensory evidence, logic and mathematics are inevitably required.[70] They are therefore part of what gets confirmed when connection between a theory and a confirming phenomenon is made, and part of what gets disconfirmed when connection between a theory and a disconfirming phenomenon is made. They are, in sum, of an epistemological piece with natural science and, so, broadly speaking, empirical.

To accommodate the lingering conviction that there is at least some difference regarding sensitivity to empirical evidence between mathematics and logic, on the one hand, and natural science, on the other, Quine argued that while both are subject to empirical revision, the precise extent or degree to which this is true is different in the two cases. He backed this view with a pragmatic conception of rational belief revision, and a view of the totality of our cognitive holdings according to which it forms a 'web' whose various parts are interdependent and ordered with respect to their importance to the preservation of the general structure of the web. At the centre of the web lie logic and mathematics, and the beliefs of natural science and common sense for the most part fan out from this towards the periphery where the entire scheme encounters sensory experience.

According to Quine's pragmatic conception of belief revision, it is to be governed by a concern to at all times maximize our overall predictive and explanatory power. A scheme of beliefs which optimizes predictive and explanatory power also optimizes our ability cognitively to cope with our environment(s), and production of such a scheme is generally aided by policies of revision which minimize, both in scope and severity, the changes that are made to a previously successful conceptual scheme in response to recalcitrant experience. If the beliefs of mathematics and logic are therefore typically less subject to empirical revision than are the beliefs of natural science and common sense, this is because revising them generally (albeit not, in Quine's view, invariably) tends towards greater upheaval in the conceptual scheme than does revision of our common sense and natural scientific beliefs.[71] Quine therefore accommodates the traditional Kantian datum that mathematics is necessary by treating logic and mathematics not as being altogether impervious to empirical revision, but only as being more so, on average, than either natural science or common sense.[72] Quine thus merges the epistemologies of mathematics and natural science into a single, albeit quantitatively differentiated, empiricist whole.

In merging mathematics and science into a single explanatory system, Quine's empiricism also induces a realist or platonist view of mathematics. It sees the world as populated by those entities needed to staff the best theory of the totality of our experience. These include not only the medium-sized objects of ordinary experience and the theoretical entities of our best current physical science, but also mathematical entities, since, as was noted above, mathematical claims play an integral role in our best total theory of experience (see [2.108], [2.109], [2.105] and [2.106]).

Quine's views have been challenged on various grounds. Field, for example, has challenged Quine's claim that the roles played by natural science and mathematics are essentially the same and cannot be differentiated. On his view there is an immense difference between the role played by mathematics and the role played by natural science in our overall conceptual scheme. Mathematics, he believes functions basically as a logic, and its theorems do not make claims that are substantive in the way that the laws of natural science are.

Another criticism is that Quine's epistemology leaves unaccounted for those parts of mathematics that are *not* somehow involved in the explanation of sensory experience. It is not clear, however, how serious an objection this is since it is not clear how much, if any, of even the least elementary, most abstract mathematics would play *no* contributory role in the simplification and explanation of sensory experience.

A final criticism is that by Parsons, who has argued that treating the *elementary* arithmetical parts of mathematics (e.g. the truth that 7 +5=12)

as being on an epistemological par with the hypotheses of theoretical physics fails to capture an epistemologically important difference regarding the different kinds of evidentness or 'obviousness' displayed by the two (see [2.95], 151). The kind of evidentness displayed by an elementary arithmetic proposition like '7+5=12' is not the same as that displayed by even such highly confirmed physical hypotheses as 'The earth moves about the sun', says Parsons. To put it roughly, the latter is more highly *derivative* than the former. Consequently, Parsons concludes, it is not plausible to regard the two claims as based on essentially the same kind of evidence and, so, the empiricist epistemology of Quine and Putnam must be regarded as being of questionable adequacy for at least the more elementary parts of mathematics.

In addition to Quine and Putnam, there have been others who have suggested different kinds of mergings of mathematics with the natural sciences. Of those, some have been empiricists, others not. Kitcher, for instance, has presented a generally empiricist epistemology for mathematics in which *history* and *community* are important epistemological forces (see [2.89]). Gödel, too, offered an epistemology in which mathematical justification was conceived along lines structurally similar to those of justification in the natural sciences.[73] In his own words:

> despite their remoteness from sense experience, we do have something like a perception also of the objects of set theory, as is seen from the fact that the axioms force themselves upon us as being true. I don't see any reason why we should have less confidence in this kind of perception, i.e., in mathematical intuition, than in sense perception…
>
> It should be noted that mathematical intuition need not be conceived of as a faculty giving an *immediate* knowledge of the objects concerned. Rather it seems that, as in the case of physical experience, we *form* our ideas also of those objects on the basis of something else which is immediately given. Only this something else is *not*, or not primarily, the sensations. That something besides the sensations actually is immediately given follows…from the fact that even our ideas referring to physical objects contain constituents qualitatively different from sensations or mere combinations of sensations, e.g., the concept of object itself, whereas, on the other hand, by our thinking we cannot create any qualitatively new elements, but only reproduce and combine those that are given. Evidently, the 'given' in underlying mathematics is closely related to the abstract elements contained in our empirical ideas. It by no means follows, however, that the data of this second

> kind, because they cannot be associated with actions of certain things upon our sense organs, are something purely subjective, as Kant asserted. Rather they, too, may represent an aspect of objective reality, but, as opposed to the sensations, their presence in us may be due to another kind of relationship between ourselves and reality.
>
> ([2.65], 483–4)

Gödel then went on to claim (Ibid., 485) that this use of and need for intuition obtains both in high-level abstract areas of mathematics such as set theory, and in the elementary areas of mathematics such as finitary number theory. He noted, moreover, that even without appeal to intuition, mathematics, like the natural sciences, makes use of what are essentially inductive means of justification.

> even disregarding the intrinsic necessity of some new axiom, and even in case it has no intrinsic necessity at all, a probable decision about its truth is possible also in another way, namely, inductively by studying its 'success'. Success here means fruitfulness in consequences, in particular in 'verifiable' consequences, i.e., consequences demonstrable without the new axiom, whose proofs with the help of the new axiom, however, are considerably simpler and easier to discover, and make it possible to contract into one proof many different proofs. The axioms for the system of real numbers, rejected by the intuitionists, have in this sense been verified to some extent, owing to the fact that analytical number theory frequently allows one to prove number-theoretical theorems which, in a more cumbersome way, can subsequently be verified by elementary methods. A much higher degree of verification than that, however, is conceivable. There might exist axioms so abundant in their verifiable consequences, shedding so much light upon a whole field, and yielding such powerful methods for solving problems…that, no matter whether or not they are intrinsically necessary, they would have to be accepted at least in the same sense as any well-established physical theory.
>
> (Ibid, 477)

Higher-level mathematical hypotheses are thus taken to be inductively justified by the simplifying, or, more generally, explanatory effects they have on lower-level mathematical truths. In a later remark, Gödel extended this characterization of inductive justification in mathematics to include not only the 'fruitful' (i.e. simplificatory and explanatory) organization of lower-level mathematical results, but

also the 'fruitful' organization of principles and facts of physics (Ibid., 485).[74]

This extension is significant because it makes a place in Gödel's mathematical epistemology for what is essentially empirical justification of mathematical truths. This does not, however, make him an empiricist like Quine. For Gödel allowed only that some of our knowledge of mathematical truths might arise from empirical sources. He remained staunchly opposed to any suggestion that all mathematical justification must or even can ultimately rest on sensory experience. Indeed, he described the empiricist view of mathematics as too 'absurd' to be seriously maintained (see p. 16 of the manuscript of his Gibbs lecture). More positively, he maintained that there is a fundamental epistemic phenomenon (viz., that of certain axioms—including certain high-level set theoretical axioms—'forcing' themselves upon us as 'being true') that cannot be accounted for by an empiricist epistemology for mathematics. This same phenomenon is apparently also that which caused Gödel to reject idealism and accept a Platonist conception of mathematics. In our estimation, neither this phenomenon nor the related question of its status as a 'datum' for the philosophy of mathematics have received the attention they deserve.

Both the empiricist Platonism of Quine and the non-empiricist Platonism of Gödel have been important influences on recent work in the field. So, too, has been an argument given by Benacerraf in the early 1970s (see [2.6]). According to that argument, mathematical epistemology faces a general dilemma. It must, on the one hand, give a satisfactory account of the truth of mathematics and, on the other, offer a satisfactory account of how mathematics can be known. This constitutes a dilemma, in Benacerraf's opinion, because while to get a satisfactory account of the truth of mathematics seemingly requires that we bring abstract objects into the picture as referents of the singular terms used in mathematical discourse, to get a satisfactory account of mathematical knowledge seemingly requires that we avoid such reference. His argument makes use of the following key claims: (i) the semantics for mathematical language should be continuous with the semantics for non-mathematical language; (ii) the deep logical form of a mathematical expression should not be treated as too different from its surface grammatical form; (iii) the semantics for non-mathematical language is referential; and (iv) the best referential semantics for mathematical language uses abstract objects as referents.

As a result of the alleged need to construe the semantics of mathematical language as referential in character, we are obliged to see the *grounds of truth* of a mathematical sentence as residing in the properties of those abstract objects to which its referring terms make reference. Thus, for example, we are obliged to say that what makes '7 +

5=12' *true* are the properties of the abstract objects 7, 5 and 12, the characteristics of the addition operation as an operation on abstract objects, and the features of the identity relation as a relation between abstract objects.

On the other hand, any epistemology for mathematics that is to avoid susceptibility to Gettier-type problems must link the *grounds of truth* of a mathematical sentence with the *grounds of belief* in it. In other words, if a given belief is to count as genuine knowledge, there must be a certain causal relationship between that which makes it true and our state of belief in it. This causes a dilemma because there is seemingly no way of securing the aforementioned causal connection while at the same time securing a reasonable referential semantics for mathematical discourse. There are mathematical epistemologies—in particular, various Platonist epistemologies—which allow for a plausible account of the truth of mathematical sentences. And there are mathematical epistemologies (e.g. various formalist epistemologies) which allow for a plausible account of how we might come to know mathematical sentences. There is, however, no known way of securing both a plausible account of mathematical truth and a plausible account of mathematical knowledge.

A great deal of recent work in the philosophy of mathematics has been devoted to trying to resolve this dilemma. So, for example, there are Field (see [2.42]) and Hellmann (see [2.68]), both of which offer anti-Platonist resolutions of the dilemma, and Maddy (see [2.92]), who attempts to work out an epistemology which is at once Platonistic and yet naturalistic. To date there is no general consensus on which approach is the more plausible.[75]

An earlier argument of Benacerraf's (see [2.5]) on another topic has been similarly influential in shaping recent developments. Perhaps more than any other single source, this paper has served as the inspiration of that recent position known as 'structuralism'. Applied to mathematics generally, structuralism is the view that

> In mathematics… we do not have objects with an 'internal' composition arranged in structures, we have only structures. The objects of mathematics, that is, the entities which our mathematical constants and quantifiers denote, are structureless points or positions in structures. As positions in structures, they have no identity or features outside of a structure.
>
> ([2.113], 530)[76]

Such a view, Resnik claims (Ibid., p. 529), is in keeping with the fact that 'no mathematical theory can do more than determine its objects up to isomorphism', a fact which seems to have led mathematicians increasingly to the view that (i) 'mathematics is concerned with structures

involving objects and not with the "internal" nature of the objects themselves' (Ibid.), and that (ii) we are not 'given' mathematical objects in isolation, but rather only in structures.[77]

Benacerraf himself applied the idea only to arithmetic, and, in particular, to the question, raised by Frege and others, of the 'deeper' ontological characteristics of the individual numbers. Frege, as is well known, held the view that numbers are objects. Benacerraf opposed this, arguing that such questions as 'Are the individual numbers really sets?' are spurious. 'Questions of the identification of the referents of number words should be dismissed as misguided in just the way that a question about the referents of the parts of a ruler would be seen as misguided.' ([2.5], 292). He then went on to complement this by noting that:

> 'Objects' do not do the job of numbers singly; the whole system performs the job or nothing does. I therefore argue…that numbers could not be objects…; for there is no more reason to identify any individual number with any one particular object than with any other.
>
> …in giving the properties of numbers…you merely characterize an *abstract structure*…and the 'elements' of the structure have no properties other than those relating them to other 'elements' of the same structure.
>
> ([Ibid., 290–1)

The primary motivation for such a view, apart from the desire for a more descriptively adequate account of mathematics, is apparently epistemological in nature. Knowledge of the characteristics of individual abstract objects would seem to require naturalistically inexplicable powers of cognition. Knowledge of at least some (e.g. finite) structures, on the other hand, could conceivably be explained as the result of applying such classical empiricist means of cognition as *abstraction* to observable physical complexes. Such abstracted structures would then become part of the general scientific framework and, as such, they could be extended and generalized in all manner of ways as the search for the simplest and most highly unified overall conceptual scheme is pursued.

Though Benacerraf and the other recent structuralists take no note of the fact, the basic idea behind their position enjoyed widespread popularity among philosophers of mathematics in the late nineteenth and early twentieth centuries. Indeed, Dedekind's essay *The Nature and Meaning of Number* ([2.25], section 73) contains an expression of the same basic idea on which the argument of Benacerraf [2.5] is centred. There Dedekind writes:

> If in the consideration of a simply infinite system *N* set in order by a transformation we entirely neglect the special character of the elements; simply retaining their distinguishability and taking into account only the relations to one another in which they are placed by the order-setting transformation , then are these elements called *natural numbers* or *ordinal numbers* or simply *numbers,* and the base element is called the *base-number* of the *number-series N*. With reference to this freeing the elements from every other content (abstraction) we are justified in calling numbers a free creation of the human mind. The relations or laws which are…always the same in all ordered simply infinite systems, whatever names may happen to be given to the individual elements…form the first object of the *science of numbers* or *arithmetic*.[78]

Similarly, Weyl contains a striking expression—indeed, a strong generalization—of the structuralist idea that mathematical objects have no mathematically important features beyond those they possess as elements of structures. He writes: 'A science can only determine its domain of investigation up to an isomorphism mapping. In particular it remains quite indifferent as to the 'essence' of its objects. The idea of isomorphism demarcates the self-evident insurmountable boundary of cognition' [2.148], 25–6.

Similar, too, were ideas voiced by Hilbert (see, correspondence with Frege in 1899, [2.71] the Paris address of 1900 [2.72] and also by Bernays ([2.9]).[79]

Structuralism as a general philosophy of mathematics is criticized by Parsons [2.98]. There it is argued that there must be some mathematical objects for which structuralism is 'not the whole truth' (Ibid., 301). The objects of which Parsons speaks are those he refers to as 'quasiconcrete'. These are so-called because they are directly 'instantiated' or 'represented' by concrete objects. Examples are geometrical figures, symbols (construed as types) whose instances are written marks or uttered sounds, and the so-called 'stroke numerals' and the like of Hilbert's finitary arithmetic. Such quasi-concrete entities are among the most elementary mathematical objects there are and they are therefore of considerable importance to the foundations of mathematics. Yet they cannot be treated in a purely structuralist way, because their 'representational' function cannot be reduced to the purely intrastructural relations that they bear to other objects within a given system.

CONCLUSION

As noted in the introduction, philosophy of mathematics in this century has been centred on the problematic laid down for the subject by Kant, which is one of the three most important influences. The other two are the discovery of non-Euclidean geometries and the rapid development of symbolic logic.

For the first three decades of the century, the Kantian problematic was for the most part understood in pretty much the way Kant himself had thought of it. That is, necessity was understood as imperviousness to empirical revision, and substantiality was understood as a kind of epistemic non-triviality. What differentiated the rival philosophies of this period, primarily, were the different responses they gave to the discovery of non-Euclidean geometries. Here, three basic alternatives eventually came to be articulated.

The first of these, developed chiefly by Frege, attempted to preserve the basic Kantian judgement that both geometry and arithmetic are necessary. At the same time, however, it sought to distinguish two different kinds of necessity, one for arithmetic, the other for geometry. This it did in response to the discovery of non-Euclidean geometries, which it regarded as having revealed a fundamental asymmetry between geometry and arithmetic—namely, that though there are, at least at the level of conceptual possibility, alternative geometries, there are not alternative arithmetics. Arithmetical thinking was therefore thought to be a more pervasive part of rational thought than is geometrical thinking. Giving a proper account of this asymmetry then came to be seen as the primary duty of a philosophy of mathematics.

The second alternative, favoured by various of the early constructivists, modified the basic Kantian judgement that both geometry and arithmetic are necessary, and maintained instead that only arithmetic is necessary. It therefore also, like the first alternative, regarded the discovery of non-Euclidean geometries as having revealed a fundamental asymmetry between spatial geometry and arithmetic. Unlike the first alternative, however, it took this discovery to be best accounted for by reducing the truly mathematical part of geometry to arithmetic and rejecting its distinctively spatial part as being of an a posteriori rather than an a priori character (which thus means that it is an object *external* to the human mind). Arithmetic, on the other hand, since it admitted of no alternatives like those which non-Euclidean geometries constitute for geometry, was to be seen as arising from a source (viz., a very general kind of temporal intuition) which was wholly internal to the human mind and, so, a priori in nature.

The third alternative, developed by Hilbert, reacted to the discovery of non-Euclidean geometry in a different way still. It sought to put them to

the test in order to determine how deeply into geometrical thinking they truly penetrate. The original non-Euclidean geometries were only shown to be independent of Euclid's axioms for plane geometry. They therefore left open the possibility that there are unknown and/or articulated features of the Euclidean plane such that, were they to be registered as axioms, the axiom of parallels *would* follow from them (together with the other axioms). They also left open the possibility that, even supposing the axioms of the Euclidean plane to be 'complete' in the sense just alluded to, the axioms needed to move from a description of the Euclidean plane to a description of Euclidean space are such that the axiom of parallels would follow from them (in conjunction with the other axioms), and would therefore not signify an independent feature of Euclidean *space*.

It was with the resolution of these matters that Hilbert was concerned. He therefore sought to produce a set of axioms so 'complete' that no axiom could be added to them without turning them into an inconsistent theory. In order to do this, he turned to a certain kind of continuity principle (viz., his so-called *Vollständigkeitsaxiom*) which, in Kantian fashion, he reckoned to belong to the domain of pure reason (or what Hilbert referred to as 'ideal' thought) rather than the domain of judgement (which Hilbert referred to as 'real' thought). This distinction between real and ideal elements in our mathematical thinking became the cornerstone of Hilbert's mathematical epistemology, both for arithmetic and, we believe, for geometry.

Hilbert did not, therefore, affirm the necessity of either arithmetic or geometry in any simple, straightforward way. Rather, he distinguished two *different* types of necessity operating both within arithmetic and geometry. One of these—that which attaches to the 'ideal' parts of arithmetic and geometry—he identified with the kind of necessity that attached to Kant's faculty of reason; a kind of necessity borne of the manner in which our minds inevitably work. The other, that applying to the so-called 'real' parts of mathematics, he saw as consisting in the presumed fact that all our thought assumes as a pre-condition the apprehension of certain elementary spatial features of simple concrete objects (cf. [2.76], 376; [2.78], 383, 385).

This, roughly, was Hilbert's complex conception of the a priority of mathematics. Clearly, it represented a significant departure from Kant's 'idealist' explanation of necessity as residing in the supposed inevitable tendencies of our minds to couch all experience in temporal terms, and all spatial experience in Euclidean terms. Clearly, too, it represented a significant departure from the ideas of the logicists and intuitionists. Its response to the discovery of non-Euclidean geometries (and such related discoveries concerning intuition of time as Einstein's theory of relativity) was not to posit an essential epistemological asymmetry between arithmetical and geometrical knowledge, as did

(the original forms of) both logicism and intuitionism. Rather, or so it seems to us, it was to try and bring both under the authority of a single type of proto-geometric intuition concerning our apprehension of the elementary shapes or forms of concrete figures.

The 1930s witnessed the demise of Hilbert's Kantian programme at the hands of Gödel's theorems. Frege's Kantian logicism had earlier been vanquished by Russell's paradox, and the Kantian philosophies of the intuitionists, too, were under assault from both philosophical quarters (where their idealism was called into question) and mathematical quarters (where their ability to support a significant body of mathematics remained in doubt). Of the programmes of the early period, perhaps Russell's non-Kantian form of logicism remained most intact, being sustained chiefly through its embodiment of the recent advances in symbolic logic and its selection as the preferred philosophy of mathematics of the then-influential logical empiricist school.

Yet, even though the positive ideas of Kant's mathematical philosophy had largely been abandoned by the 1930s, his basic apparatus remained in effect until the early 1950s. It was only with Quine's attack on the analytic/synthetic distinction of the positivists that its influence, too, began to slip.[80] The dominant trend in the philosophy of mathematics since then, if, indeed, there has been one, has been that of empiricism: an empiricism which denies that there is a difference in kind between the necessity of mathematics and that of the rest of our judgements; an empiricism which sees mathematics as governed by the same basic inductive methodology as governs the natural sciences; an empiricism which sees mathematical inference as reducible to logical inference. The ultimate adequacy of this overall empiricist approach as an explanation of the 'data' of mathematical epistemology, however, remains unclear. So, too, does the justification of its view of what these data are. Indeed, the problem of determining what are the data of the philosophy of mathematics is, I would suggest, among the more serious problems facing the subject as the century draws to a close.

NOTES

1 Years later, in his only philosophical essay (see [2.91]), Kronecker would quote this view with approbation.

2 Ironically, it is probably the continued development of logic in the latter three-quarters of this century that has contributed as much as anything to the blindness of present-day philosophy of mathematics to the Kantian question of whether mathematical proof *can* rightly make use of logical inferences.

There are, of course, reasons for this new orientation. There are also, however, some drawbacks as we see it. Cf. Detlefsen [2.28], [2.30], [2.33] and Tragesser [2.142] for attempts to revitalize the Kantian question.

3 In speaking of a logicism 'like Russell's', we mean a logicism which was applied to the whole of mathematics and not just its arithmetic portion. The very different logicisms of Frege and Dedekind would not have been nearly so attractive to the logical empiricists because, though they would have allowed an analytic treatment of arithmetic judgement, they would not have allowed this account to be extended to geometry. The logical empiricists would therefore have had to deal with the seeming 'necessity' of geometrical judgement in some other way.

4 This it did by allowing them to treat mathematical judgement as analytic judgement, which they then treated as arising from the general phenomenon of linguistic convention. More on this later.

5 It should be noted, however, that the logicism of Frege and Dedekind raised a challenge to Kant on this score too. For it programmatically required that all reasoning appearing in a mathematical proof be reducible to logical reasoning and, indeed, logical reasoning of a sort so clear and perspicuous that it could not conceal anything of a non-logical nature.

6 Cf. [2.47], 50. [My translation.]

7 Frege expanded a bit further on this idea in section 24, where similar ideas in Locke and Leibniz are cited. See also [2.50].

8 In a later remark (cf. the introduction to [2.52], xv), Frege clarified further the connection between the laws of logic and the laws of thought alluded to here. 'The laws of logic have a special claim to be called "laws of thought" only because we recognize them as the most general laws, which prescribe universally the way in which thought ought to proceed when it proceeds at all.' (my translation).

9 This criticism of Kant would apply even more powerfully to Leibniz, since the latter acknowledged only *one* basic source of knowledge (namely, reason) and saw all truth as analytic in character (and, so qualitatively the same). It seems likely therefore that Frege would not have found Leibniz's mathematical epistemology as satisfying as Kant's—and this despite the fact that Leibniz advocated a kind of logicist view.

10 Frege says (cf. [2.49], the first footnote in section 3) that he has tried to capture what earlier writers, and, in particular, Kant, had in mind in their usages of the above terms. This is difficult to accept at face value, however, since Frege insists that *both* the a priori/a posteriori distinction *and* the analytic/synthetic distinction 'concern…not the content of a judgement but the justification for making the judgement' (Ibid., section 3), whereas Kant held only that the former is a distinction of this sort. Furthermore, Frege later (cf. [2.49], section 88) says that Kant underestimated the potential epistemic productivity of analytic judgements because he 'defined them too narrowly'. What he seems to mean by this is that Kant, because of his impoverished Aristotelian notion of logical form, defined analyticity only for subject-predicate propositions, whereas, of course, the notion applies to a much wider class of propositions. There is, however, no indication that Frege saw Kant as having intended the analytic/synthetic distinction to concern the content of a judgement rather than its justification.

It should also be noted that in the event that canonical proofs are allowed to be non-unique, the definitions of syntheticity and a posteriority would have to be changed to require that every canonical proof involves recourse to a truth of a special science (resp. involves an appeal to facts). Likewise, the definitions of analyticity and a priority would have to be changed to state that some canonical proof contain only general logical laws and definitions (resp. only general laws which neither need nor admit of proof).

11 Cf. [2.49], section 14.

12 Though Frege does not cite the original source of his inspiration, the main idea expressed clearly reverberates a remark from the preface of the first edition of the *Critique of Pure Reason:* 'in an inventory of that which is acquired by us through Pure Reason…nothing can escape us. For whatever reason brings forth *(hervorbringt)* entirely of itself cannot be hidden from it' (xx).

13 Cf. also section 27 where he says that numbers are neither 'spatial and physical…nor yet subjective like ideas, but non-sensible and objective' and that 'objectivity cannot…be based on any sense-impression, which as an affectation of our mind is entirely subjective, but only…on reason'.

14 Cf. [2.49], sections 69, 107.

15 On this latter, compare [2.49], section 48.

16 Frege's belief in the priority of concepts cannot, however, completely explain his opposition to Kant. For Kant as is well-known, believed in a *form* (as opposed to a *substance* or *content*) of intuition which 'precedes in my subjectivity all actual impressions through which I am affected by objects' (cf. [2.85], section 9, my translation) and held it to be the basis of our mathematical knowledge. He was therefore not committed to a conception of the intuitional basis of our mathematical knowledge according to which it rests on intuitions of particular sensible things. Why, then, did Frege feel that he needed concepts rather than merely Kant's *forms* of intuition? This, I believe, is a difficult question to answer. Such answers as might be given would appear to require recourse to Frege's belief that (i) concepts possess *special* unifying power (and, in particular, unifying power that is superior to that possessed by intuition generally); and that (ii) number is applicable to more than just that which can be sensed. Kant, by contrast, held that

> all mathematical cognition has this pecularity: that it must first exhibit its concept in intuitional form… Without this, mathematics cannot take a single step. Its judgements are therefore always intuitional, whereas philosophy must make do with discursive judgements from mere concepts. It may illustrate its judgements by means of a visual form, but it can never derive them from such a form.
>
> (Ibid., section 7).

17 Of course, quite apart from worries concerning its consistency, one might wonder how Rule V could be defended as a *logical* principle. In his defence, Frege employed his well-known distinction between sense and reference (which is related to his belief in the priority of concepts to their extensions) and constructed an argument to the effect that the two sides of the biconditional in Rule V have the same *sense*.

18 For more on this, as well as some examples, see [2.49], sections 64–66, 70, 88, 91.

19 Frege gives an example of the different ways of carving up content in section 70 of [2.49]. He also discusses it in section 9 of [2.48], where one of the example he considers is the proposition of 'Cato killed Cato'. He remarks there that if we think of this proposition as allowing for replacement of the first instance of 'Cato', we see it as formed from the propositional function 'x killed Cato'. If we think of it as allowing for the replacement of the last instance of 'Cato', we see it as formed from the function 'x was killed by Cato'. And, if we see it as allowing for the replacement of both occurrences of 'Cato' at once, we see it as formed from the function 'x killed y'. No single one of these ways of seeing the proposition is necessary for its apprehension. Hence, each might in its turn be thought of as a 'recarving' of its content.

20 Still, as was mentioned earlier, since Russell believed that the whole of what is ordinarily regarded as pure mathematics can be reduced to (second-order Peano) arithmetic, the distance between him and Frege on this point is not so great as might at first sight appear (cf. Russell [2.123], 275–9 (esp. 276); [2.120], 157–8, 259–60). It should be noted, too, that in these passages, Russell describes the work of the 'arithmetizers' of mathematics (e.g. Dedekind and Weierstrass) as being of greater importance to the cause of logicism than the discovery of non-Euclidean geometries.

21 Even here, of course, one sees vestiges of Kant. For he, too, conceived of reason as impelling one towards ever greater generality in science. He did not, however, think of this procedure as tending towards a terminus—a most general science (the TRUE science!), as it were. Still less did he think of it as tending towards a science of *logic*.

22 Hereinafter we will refer to this as Russell [2.120]. The pagination cited is that of the seventh impression of the second edition, which appeared in 1956.

23 Russell distinguished the level of generality where all constants are logical constants from what we are hero referring to as the level of *maximum* generality. The latter was seen as requiring the former. But in addition, it was taken to require an identification of what Russell referred to as the 'principles' of logic; that is, the most basic truths from which all other truths whose only constants are logical constants can be derived by logical means (cf. [2.120], 10).

24 Russell elaborated on this idea and extended a modified version of it to the case of the empirical sciences in [2.122] and [2.123].

25 Russell [2.123], 273–4. Page numbers are those of the reprint in [2.125].

26 It is not obvious that Russell's condition is weaker. Indeed, it is not weaker at all if a suitably stiff standard of individuation for propositions is adopted. For example, if one were to adopt a criterion of individuation which makes all logically equivalent sentences express the same proposition, then Russell's criterion would become considerably more demanding than he wanted it to be. Moreover, the problems intensify the broader one's notion of logical equivalence becomes. Hence, for the logicist, who requires a very broad conception of logical equivalence, a criterion of propositional identity that identifies logically equivalent propositions would make it virtually impossible for a standard of inferential epistemic productivity like Russell's to succeed. Russell did not explicitly propose any standard of individuation for propositions in his discussion of synthetic inference, but his remarks suggest that he would not have accepted a standard which implies the identity of logically

equivalent sentences (at least for any broad conception of logical equivalence).

27 We must leave for another occasion the explanation of how this differs from Kant's understanding of reason as a regulative ideal that leads us to ever greater generality (i.e. unity) in our judgements.

28 The reader will recall that in 1886 Kronecker famously remarked that while God made the whole numbers, everything else is the work of man *(Die ganzen Zahlen hat der liebe Gott gemacht, alles andere ist Mensckenwerk)*. How do we square that Kronecker with the Kronecker who accepted Gauss's view that the numbers are the product of the human intellect and that geometry is not? The answer would seem to lie in a distinction Kronecker made between arithmetic in a 'narrower' sense and arithmetic in a 'wider' sense. By the former, he meant the arithmetic of the natural numbers, while by the latter he meant to include algebra and analysis as well (cf. [2.91], 265). A resolution of the apparent conflict can be obtained by taking the work of God to be arithmetic in the narrower sense and taking the 'everything else' of Kronecker's remark to refer not to geometry and mechanics and the like, but to arithmetic in the wider sense.

29 Page references to Brouwer's papers are to the reprinting in [2.20].

30 Poincaré, another early constructivist, about whom we shall have more to say later, differed both from Kant, Brouwer and the other early constructivists on this point. He maintained that 'the axioms of geometry…are neither synthetic a priori judgements nor experimental facts… They are conventions…merely disguised definitions' (cf. [2.99], pt. II, ch. 3, section 10). For a statement (not wholly accurate, in my view) of some of the other differences, see [2.21], 2–4.

31 Poincaré, along with Borel and Lebesgue, was described by Brouwer (cf. [2.21], 2–3), as a 'pre-intuitionist'. For present purposes, however, the alleged differences between 'pre-intuitionism' and 'intuitionism' are of no importance.

32 Cf. 'Revue de metaphysique et de morale' 14:17–34, 294–317, 627–50, 866–8; 17:451–82; 18:263–301; [2.121], 412–18, 15:141–3.

33 As he put it elsewhere, it is a mistake to believe in:

> the possibility of extending one's knowledge of truth by the mental process of thinking, in particular thinking accompanied by linguistic operations independent of experience called 'logical reasoning', which to a limited stock of 'evidently' true assertions mainly founded on experience and sometimes called axioms, contrives to add an abundance of further truths.
>
> (Cf. [2.19], 113)

34 Brouwer, of course, believed that there can be significant differences between the class of theorems provable from a given set S of propositions by means of classical logic and those provable from S by means of intuitionistic mathematical reasoning. He would not, however, have maintained the same for the theorems provable via intuitionist logic from S and the theorems provable by genuine mathematical reasoning from S.Still, he saw an important difference between proving theorems by genuine mathematical means and proving them by means of intuitionist logic. Indeed, the central theme of his critique of classical mathematics was that mathematical reasoning is distinct from logical reasoning

generally, and not just from *classical* logical reasoning. For more on this, see [2.28].

35 Poincaré was led to his intuitional conception of inference by his belief in what he took to be a fundamental datum of mathematical epistemology; namely, that the epistemic condition of a purely logical reasoner, who sees none of the local architecture that creates the 'channels', as it were, of mathematical inference, is different from that of the genuine mathematician whose inferences reflect a grasp of these channels. Brouwer, in effect, held much the same view. For he insisted that logical inference reflects only a grasp of the channels of belief-movement provided for by the linguistic representation of belief, whereas genuine mathematical inference moves according to the channels provided by that constructional activity which itself is *constitutive* of mathematics.

36 There are, however, foreshadowings of such a notion in the Christian neoplatonists (e.g. Augustine, Boethius and Anselm) and also in Cusanus. The latter even coined a term for the notion—*visio intellectualis*. Kant, too, spoke of such a notion (cf. [2.86], 307, 311–12; and [2.87], vol., VIII, 389), though he thought that only God and not humans could possess it.

37 As Kant said (cf. ist edn of [2.86] (which was published in 1781), 639, [2.86], 667):

> In whatever manner the understanding may have arrived at a concept, the existence of its object is never, by any process of analysis, discoverable within it; for the knowledge of the existence of the object consists precisely in the fact that the object is posited in itself, outside the mere thought of it.

38 The First Act of Intuitionism says that mathematics is to be 'completely separated…from mathematical language and hence from the phenomenon of language itself described by theoretical logic' ([2.21], 4–5).

39 'to exist in mathematics means: to be constructed' ([2.15], 96). 'Mathematics is created by a free action' (Ibid., 97).

40 Cf. [2.34] for a more detailed development of these and related matters.

41 Cf. [2.34] for a more detailed discussion of these matters.

42 Conclusive textual evidence that Hilbert intended to use finitary intuition as the foundation for both our geometrical and our arithmetical knowledge may not exist. If we are right, however, in thinking that this was Hilbert's view, then, he not only would have regarded both arithmetic and geometry as a priori, but would have taken both as being based on the *same* a priori intuition.

43 Cf. [2.74], 163, and [2.80], 32 for related remarks.

44 Examples of unproblematic real propositions are variable-free equations of arithmetic and prepositional compounds formed from them. The sentences in this class can be manipulated according to the full range of classical logical operations without leading outside the reals. As examples of problematic real propositions, Hilbert offered the following: (i) for all non-negative integers **a, a**+1=1+**a;** and (ii) there is a prime number greater than **g** but less than **g!** +1 (where **'g'** stands for the greatest prime known at the moment), (i) was deemed problematic because its denial fails to bound the search for a counterexample to '**a**+1=1+**a**'. Hence, its denial is not a real proposition, and,

so, the law of excluded middle cannot be applied to (i), making it problematic. In like manner, (ii) classically implies 'there is a prime number greater than **g**'. This was not regarded as a real proposition since it gives no bound for the search for the prime it asserts to exist, and, by the definition of **g** (as being the largest prime known), any such bound would go beyond everything that is known. Hence (ii), too, was regarded as leading to non-finitary conclusions when manipulated according to the principles of classical logic and is therefore problematic. We are not sure that Hilbert's reasoning regarding this last case is ultimately capable of sustaining his conclusion. This does not, however, in our estimation, threaten the cogency of his distinction between problematic and unproblematic reals.

45 To be more exact, what was to be prohibited was the use of ideal methods that conflict with real methods in the sense that they generate real theorems that are *refutable* by finitary means. We will refer to this as *real-consistency*. This may signal a difference between Kant and Hilbert. For while Kant wanted to proscribe all uses of reason that transcend what is determinable by the senses, Hilbert, on the other hand, seems to have been primarily interested in prohibiting uses of ideal reasoning that are refutable by finitary reasoning. What he would have said about ideally proven real theorems that are neither provable nor refutable by finitary means is less clear.

It is also important to note in this connection that there is an asymmetry between the observation sentences of an empirical science and Hilbert's real sentences. This asymmetry consists in the fact that observation sentences are, by their very definition, to be decidable by observational evidence. Real sentences, on the other hand, are not understood as being necessarily decidable by finitary or real means. Thus, while it is possible to pass from a requirement that no observational consequence of an empirical theory be observationally refutable to a requirement that every observational consequence be observationally verifiable, it is not similarly possible to pass from a requirement that no ideally provable real theorem be refutable by real means to a requirement that every real theorem provable by ideal means be provable by real means. For more on this, see [2.29].

46 The salient feature of a formal system for the purposes of this discussion is that its set of theorems is recursively enumerable.

47 **PRA** has as its theorems all logical consequences of the recursion equations for (formalizations of) the primitive recursive functions. In addition, it admits mathematical induction restricted to (formulae formalizing) primitive recursive relations. Cf. [2.135] for an extended argument to the effect that **PRA** is a formalization of finitary reasoning.

48 For a useful discussion of this 'relativized' form of Hilbert's programme, see the very nice expository paper [2.40].

49 $\mathbf{WKL}_0$ is the theory obtained by adding the so-called *weak König's lemma,* (i.e. the claim that every infinite subtree of the complete binary tree has an infinite branch) to a system called $\mathbf{RCA}_0$, which contains the usual axioms for addition, multiplication, 0, equality and inequality, induction for Σ_1 formulae, and comprehension for Δ_1 formulae (i.e. all instances of the schema $\exists X\, \forall n\, (n \in X \leftrightarrow \phi(n))$ where ϕ is any Σ_1 formula such that there is a Π_1 formula ψ to which it is provably equivalent). It should also be mentioned that the proof of (ii); which is due to Harvey Friedman, actually establishes something

stronger than (ii); namely, that all Π_2 theorems (i.e. theorems equivalent to a sentence of the form '$\forall x \exists y\ \phi xy$', where '$\phi xy$' is a recursive formula) of $\mathbf{WKL}_0$ are provable in **PRA**. Finally, it should be noted that these same results are obtainable for a stronger system $\mathbf{WKL}_0^*$, which contains some non-constructive theorems of functional analysis not provable in $\mathbf{WKL}_0$. For more on this, see [2.134]. Cf. [2.133] for a more thorough bibliography concerning the work establishing (i) and (ii).

50 It is not just the ideal derivation of a real theorem τ_P which, by itself, is to be simpler than any real proof of τ_R. For that ideal derivation of τ_R must be supplemented with a metamathematical proof of **I**'s real-soundness if we are to obtain a genuine justification for τ_R from an ideal derivation of it. For a more thorough discussion of this and related matters, see [2.27], chs 2 (esp. pp. 57–73). 3 and 5, and [2.29].

51 Cf. [2.29], 370, 376 for a bit more on this.

52 Stated intuitively, the axiom of reducibility says that for every prepositional function f, there is a predicative prepositional function P_f such that f and P_f have the same extension.

53 Ayer stated the predicament of the empiricist well:

> Whereas a scientific generalization is readily admitted to be fallible, the truths of mathematics and logic appear to everyone to be necessary or certain. Accordingly the empiricist must deal with the truths of logic and mathematics in one of the two following ways: he must say either that they are not necessary truths, in which case he must account for the universal conviction that they are; or he must say that they have no factual content, and then he must explain how a proposition which is empty of all factual content can be true and useful and surprising.
>
> ([2–2], 72–3)

54 The former kind of proposition was called *analytic* and the latter kind *synthetic*.

55 In the case of Carnap (cf. [2.24]), this thesis of analyticity was developed by introducing the notion of a *linguistic framework*, which he understood as a system of rules for talking about entities of a given kind. Linguistic frameworks induce a distinction between *internal* and *external* questions of existence. Answers to internal questions, such as the question 'Is there a prime number greater than 100?', come from logical analysis based on the rules governing the expressions making up the framework. Answers to such questions are therefore logically or analytically true. External questions querying the general existence of the entities associated with a given linguistic framework are to be interpreted as questions regarding acceptance of the framework itself (Ibid., 250). Thus, the question 'Do numbers exist?', is to be understood as 'Should the linguistic framework of numerical discourse be accepted?'. Answers to such questions are to be decided on what are basically pragmatic grounds; that is to say, on the basis of the 'efficiency' of the framework in question as an 'instrument', or, in other words, on the basis of 'the ratio of the results achieved to the amount and complexity of the efforts required' (Ibid., 257). This view has often been described as a form of

conventionalism, though use of this term would seem to disguise its essentially pragmatist flavour. It also tends to confuse the position of Carnap's later writings on the nature of mathematics with that of his earlier writings, which truly was conventionalist in character. For more on this latter point see [2.116].

56 Sharing some of the general spirit of Bostock, but more concerned to defend (a version of) logicism, are Hodes [2.81] and [2.82].

57 This kind of logicism is closely related to the 'structuralist' position discussed below.

58 The views of Quine and Putnam are stated and discussed below. See also the discussion of Benacerraf's dilemma given there. Field seems mainly to be motivated by a desire to find a physicalist solution to this dilemma.

59 For the beginnings of a defence of the Kantian view, see [2.28], [2.30].

60 Cf. Field [2.43], 516, n. 7, where he cites this as the key feature distinguishing his modalization of mathematics from the earlier one of Putnam [2.102].

61 Basically, the idea is that if one has need of a given capacity, and could also benefit from its improvement, then one will be rationally impelled to bring about such improvements.

62 Heyting referred ([2.70], 108) to this thesis as the 'principle of positivity', and acknowledge that it is the chief determinant of the character of his logic.

63 'a logical theorem expresses the fact that, if we know a proof of certain theorems, then we also know a proof for another theorem' ([2.70], 107).

64 There is some question as to what exactly this means. Does it mean that one who knows the meaning of a mathematical sentence S either knows or can readily obtain either a proof or a disproof of S? Or does it mean, instead, that one knows the meaning of S when and only when he or she *would* recognize a proof or a disproof of S *were* he or she to be *given* it? See [2.93], [2.94] and [2.140] for more on this topic.

65 This is not said as a criticism of Dummett. For he states explicitly that his conception and defence of intuitionism is not intended to comport with that of Brouwer or Heyting or any other particular intuitionist ([2.36], 215).

66 (ii') is not altogether uncontroversial, however. For it equates legitimate ascription of implicit knowledge to a speaker with implication by the best total theory of his or her behaviour. In doing so, it fails adequately to reflect the fact that that theory of a speaker's behaviour which, judged by 'local' standards, qualifies as best might have to be sacrificed in order to obtain the best global theory (i.e. the best total explanation of *all* phenomena—not just those constituting the speaker's behaviour). Changing (ii) in this direction would, however, only intensify the objection to Dummett's argument developed here.

67 On occasion when I've presented this argument I've been met with the charge that it presupposes a holistic view of meaning and that that is something Dummett explicitly rejects. This latter claim is clearly true ([2.36], 218–21). It is, however, a misunderstanding of my argument to think of it as presupposing a holistic view of meaning. Indeed, the alternative I suggested above to Dummett's view of implicit knowledge is one that sees implicit knowledge (and hence knowledge of meaning) as consisting in the occupation of a specific mental or psychological or neural state that underlies the behaviour with which Dummett wants to equate it. Our claim is that even such a non-holistic view of meaning as this is subject to underdetermination by the observed facts of speaker behaviour. The basis of our objection is therefore not acceptance of a holistic view of

meaning, but rather acceptance of the general idea of underdetermination of theory by data. Regardless of whether Dummett has produced convincing reasons for rejecting holism (and we believe he has not), he has provided no reasons for rejecting the idea of underdetermination of theory by data.

68 Indeed, in his 1939 Cambridge lectures on the foundations of mathematics ([2.150], 237), Wittgenstein dismissed intuitionism as 'bosh'.

69 For useful discussions of Wittgenstein's views, the reader should consult [2.35], [2.152], and [2.129]. The latter is especially recommended for the many stimulating questions and challenges it raises for the more influential interpretations of the later writings.

70 Putnam [2.106] strengthens this to say that in order even to *formulate* science, mathematics is needed.

71 On the 'web' metaphor, this is what is meant by saying that they are 'centrally located'.

72 Nor is this merely lip service. For Putnam has argued that the best way of clearing up certain paradoxes in quantum physics may be to revise classical two-valued logic or classical probability theory [2.104].

73 His view was not, however, empiricist. This is so because he rejected the idea that sensory intuition is the ultimate basis for (at least most of) mathematical knowledge. He posited instead a distinctively mathematical form of intuition, though this mathematical intuition was interpreted in a realist or platonist manner, as a means of gaining acquaintance with externally existing objects, and not in a Kantian manner, as an a priori form or condition of thought.

74 Gödel notes in the same place, however, that, at present, so little is known about the lower level mathematical and physical effects of such higher level axioms as those concerning the existence of various kinds of so-called 'large cardinals' that inductive justification of the kind just noted is not possible.

75 My own inclination is to think that Benacerraf's dilemma is not a genuine dilemma. In particular, I am inclined to reject claim (i) of the argument leading to the dilemma—that is, the claim that we are under some sort of obligation to treat mathematical language as semantically continuous with non-mathematical language. What does seem to be an obligation is that we treat mathematical language as a congruous element of our larger linguistic system, conceived of as a device for manipulating representations of the world. In general, I take language to play the role in human thought of allowing us to substitute manipulation of representations of the world for manipulations of the world itself. But schemes for substituting manipulations of representations of the world for manipulations of the world itself (conceived in either realist or idealist terms) can certainly be so fashioned as to make room for sub-devices whose significance within the scheme is that of a calculary or computational device rather than that of a referential device. Sometimes syntactical manipulation of signs might be better than direct semantical manipulation as a way of managing what, in the end, is to be a representation-manipulation. That being so, syntactical manipulation might well play an important role in a greater overall scheme of basically semantical representation-manipulation. At the same time, however, it is hardly to be supposed that such devices are to be treated as semantically continuous with the more referential parts of the linguistic scheme. Nor is

there any reason I can see for denying that the role of mathematical language within our overall linguistic scheme is that of a calculary or computational device. As a result, I see little grounds for accepting Benacerraf's (i) and the ensuing 'dilemma' that is built upon it.

76 For another statement to this general effect, see [2.131], 534.

77 See the remarks from Weyl quoted below for a relatively early statement of just this idea.

78 For more on the ideas expressed here, the interested reader should consult the correspondence with H. Weber in volume III of Dedekind's *Gesammelte mathematische Werke*. For worthwhile discussions of Dedekind's views, see [2.136], [2.137] and [2.98], section 2.

79 The general prevalence of such views around the turn of the century is also noted in [2.148] and [2.10].

80 I would except Hilbert's later philosophy of mathematics (and, in particular, that expressed in [2.78]) from this generalization.

I would like to thank Aron Edidin, Richard Foley, Alasdair MacIntyre, Alvin Plantinga, Phillip Quinn, Stuart Shanker and Stewart Shapiro for reading and helpfully commenting on all or parts of this chapter. The mistakes that remain are mine alone.

CHAPTER 3

Frege

Rainer Born

LIFE IN INTELLECTUAL CONTEXT

Gottlob Friedrich Ludwig Frege was born on 8 November 1848 at Wismar Mecklenburg, Germany and died on 26 July 1925 at Bad Kleinen (south of Wismar). He was initially a mathematician and logician and finally became a very important philosopher in the field of analytical philosophy (depending of course on one's understanding or conception of philosophy).

Today it is usually undisputed that Frege was the real founder of modern (mathematical) logic, i.e. he is considered to be the most important logician since Aristotle. In his philosophy of mathematics (more precisely his philosophy of arithmetic), the so-called 'logizism', in which he attempted to reduce arithmetic to logic alone, depending on one's understanding of logic), Frege was concerned with the foundations of mathematics and provided the first contribution towards a modern philosophical discussion of mathematics.

Furthermore, Frege is considered to be the founder of philosophical logic and analysed language from a philosophical-semantic point of view (philosophy of language). In this respect he can be considered to be the grandfather of a modern, linguistically orientated analytical philosophy.[1]

Frege studied mathematics, physics and philosophy at Jena and Göttingen. Among his teachers was Hermann Lotze, who by some (e.g. Hans Sluga) is considered to have influenced the development of Frege's 'functional' conception of logic.[2] He wrote his doctoral thesis in 1873 at Göttingen about a geometrical representation of the imaginary entities in the plane *(Über eine geometrische Darstellung der imaginären, Gebilde in der Ebene)*[3] and was appointed University Lecturer in mathematics in 1874 at Jena with a second dissertation about 'Methods of calculation founded

upon an extension of the concept of magnitude', *(Rechnungsmethoden, die sich auf eine Erweiterung des Größenbegriffes gründen)*.[4] He was professor at Jena from 1879 to 1918 and in 1879 he was made extraordinary (and in 1896 ordinary) honorary professor.

During his lifetime Frege received little scientific acknowledgement and he died an embittered man.

Russell, Wittgenstein and Carnap, tried to promote Frege's ideas, but entitled the chapter *Gottlob Frege* in Philip E.B.Jourdain's 'The Development of The Theories of Mathematical logic and the Principles of Mathematics', which drew attention to Frege's work. It was not until the publication of the 'Philosophy of Arithmetic' *(Grundgesetze der Arithmetik)*, which Frege himself read and supplemented with commentaries, that his reputation was established. Frege considered it to be his life's work to produce incontestable foundations for elementary number theory and analysis.

Frege's published work can be divided into three important periods:

Early period:	*(1879–1891)*	*Reference number*
Begriffsschrift *(BS)*	(1879)	[3.3]
Grundlagen der Arithmetik *(GLA)*	(1884)	[3.6]
Mature period:	(1891–1904)	
Grundgesetze der Arithmetik I *(GGAI)*	(1893)	[3.11]
Grundgesetze der Arithmetik II *(GGAII)*	(1903)	[3.14]
Funktion und Begriff *(FB)*	(1891)	[3.8]
Sinn und Bedeutung *(SB)*	(1892)	[3.9]
Über Begriff und Gegenstand *(BG)*	(1892)	[3.10]
Was ist eine Funktion *(WF)*	(1904)	[3.15]
Late period:	(1906–1925)	
Der Gedanke *(LUI)*	(1918)	[3.16]
Die Verneinung *(LUII)*	(1918)	[3.17]
Das Gedankengefüge *(LUIII)*	(1923)	[3.18]

Further important insights can be gained by studying the *Nachlaß (NL)* [3.19] and the *Briefwechsel (BW)* [3.19]. These abbreviations are used internationally.

FREGE AND MODERN LOGIC

Summing up Frege's contribution to logic retrospectively speaking, i.e. from a modern point of view and with the knowledge of modern developments, one could say that Frege in his *BS* [3.3] for the first time produced a logical system with formalized language, axioms and rules for inference. The later logical system of the *GGAI* [3.11][6] is concerned with what today we call the second-order predicate calculus (quantification over objects and properties). The fragments of sentence and predicate logic of first order contained in the *BS* build—as we know today—a complete formalization of deductive logical theories. Frege's achievement in logics is comparable to Aristotle's with respect to 'syllogistics'. From the point of view of philosophy of science one can interpret the *BS* as a sort of preparation for the logical foundation of arithmetic, as the development of the instruments to achieve this aim.

In this section, I shall give a short survey of Frege's achievements in formal logic from a modern point of view.[7] Then, I shall deal with some philosophical considerations, which are especially important for our investigations. Finally, I shall briefly touch upon predicate logic and the transition from Frege's *BS* to his *GGA*. In doing so, I would like nevertheless to emphasize that one first has to make oneself familiar with a given field of knowledge,[8] so that one has a fund of examples at one's disposal and, while analysing and thinking about it, is able to gain new insights.[9] This is in accordance with posthumus interpretations of Frege's procedures, with what might be called his constructivist approach,[10] and which one should distinguish from Husserl's abstractivistic approach.

Frege's essential contribution to modern logic consists in the introduction of (logical) quantifiers, which helped to solve problems that hitherto had turned up in the logical analysis of general sentences, i.e. sentences containing expressions like 'for all', 'some', 'there exists one' (and perhaps only one), 'there exists at least one', etc.[11] The unsatisfactory attempts to analyse these sentences in a formal logical way had prevented substantial progress in logics since Aristotle.[12]

One can argue that from a logical point of view Frege analysed these sentences in such a way that they could be considered as names for truth-values. This means that he considers just judgeable expressions, i.e. sentences which possess a 'judgeable content', an idea that later, in connection with problems concerning the identity-relation between statements, led to the invention of the term 'sense' *(Sinn)* as distinct from 'reference' *(Bedeutung)*.

One can interpret this in the following way: when Frege uses '-' in front of some A (he calls '-' the content stroke) this means (to Frege, reconstructively speaking) that in analysing A one is abstracting from everything except from the fact that the expression A must be judgeable and that one can positively assert it, i.e. turn it into a statement, whereby the sentence (in the logical sense) thus 'created', i.e. being considered as a sentence,[13] can be true or false. In this case Frege uses what he calls judgment-stroke '|'and writes '⊢A' (asserting *that* A).

The way in which A is related to its content-A is then (explanatorily speaking) simulated by relating it to (letting it refer to) ⊢A, to a truth value. Thus '⊢A' (in modern language) can (very cautiously and for reasons of reconstruction) also be considered as an expression for a truth value variable. The 'truth values' themselves can be interpreted/considered as belonging to the 'realm of the objective' (in Frege's sense).

From an external, theoretico-explanatorical point of view, we are here concerned with simulations, and the truth values are so-called 'constructs'. From an internal, so-to-speak philosophical point of view, we have to consider that the idea of sentences as 'names for truth values' can be useful or not, i.e. as an explanatory concept which can be projected onto our understanding of what it is to be a sentence.

Kutschera, however, insists that Frege's logical operations are not defined for truth values or judgeable contents but for sentences, and sentences are not analysed as names but are names for truth-values ([3.46], 24).

Perhaps one should empasize that in the context of logic the expression 'sentence' has a primarily technical meaning, i.e. grammatical sentences are replaced (thought of) in such a way that their relation to real objects (our intimate experience of where it makes sense to talk of real objects) is simulated by the relation of sentence signs (names) to truth values, i.e. a sentence can be a name for a truth value. So the point is that sentences are analysed *as* functions.

The greatest difficulty in presenting Frege's 'logic'—especially if one analyses the original papers—is that one cannot simply immerse oneself in the background knowledge of Frege's time. We cannot really ignore our so-called modern knowledge, it will always influence our interpretation, as Kutschera illustrates in [3.46].

In the following considerations, I shall therefore resort to an approach that does not rest purely on linguistic means.

Frege in *BS* starts by introducing the distinction between variables and constants, then introduces an expression for judgements and goes on to introduce 'functions' as a new means for analysing linguistic expressions (a means distinct from the classical subject—predicate

analysis). He is thus able to circumvent the classical approach to logic, which starts with concepts, goes on to judgements, and ends with inferences.

Frege explicitly starts with judgements and later, after extending the mathematical concept of functions, shows that concepts can be analysed as special functions. In regarding a linguistic expression as a function, he considers the expression as the result of the application of a function, i.e. as the value of a function (in the modern sense).

In *BS* Frege talks only of signs and sign sequences which announce the content of a judgement, i.e., if A is such a sign in our language (a meaningful linguistic expression that refers to some fact in the world), then '-A'[14] is an expression for the idea to consider the sign A under the aspect that A expresses some content. Frege himself circumscribes this in normal language as 'the sentence that' or 'the fact that'. Later in *GGA* Frege very precisely distinguishes between a sign and what it designates and develops a logic of terms. In *BS* a judgement seems to be a statement that claims to be true or false.

But not every 'content' '–A' can be turned into a judgement (using the judgement stroke '|' as a means of expression, '⊢A'), i.e. turned into a claim about a fact that obtains/contains (or not) a true or false statement. According to Frege, one has therefore to distinguish between 'contents' that can be turned into judgements and contents for which this is not the case. The following remark by Frege in the *BS* is important:

'The horizontal stroke "–" in the sign "⊢" combines the signs or sign sequences following upon it into a *whole* (my emphasis). And the affirmation which is expressed by the vertical stroke at the left of the horizontal line concerns the sign sequence considered as a whole' [3.3], 2.[15] 'What follows upon the content stroke therefore must always be a "judgable content"' (Ibid.).[16] Thus, '⊢A' expresses the fact that the content '–A' is claimed or can be claimed.

In Frege's calculus one more or less stays within the given language. One considers linguistic expressions under a certain aspect of analysis but has to enrich the ontology, i.e. to locally refine the expressive power of the means of expression, the language. In other words, we are talking within a language about that language.

One can understand this procedure as a sort of simulation, i.e. as the picture that, just as a language is referring to the/some world, the claim '⊢A' refers to some content ' –A' as existing within the world our natural language refers to from the beginning. This means that the special matters in a natural language are simulated by some mapping or assignment '⊢A $\mapsto$ –A' within the given language.

It is interesting to see how Frege introduces what today are known as logical operators. Frege uses only two: negation and what today is called material implication, and uses a two-dimensional notation in analogy to

arithmetics, as he explains in '*Berechtigung,* 54' ([3.4]). The logical operators are defined for sentences or for linguistic expressions.[17] To my mind, however, and for matters of analysis, one should distinguish between a 'sentence' in the logical reconstruction/analysis and a sentence as element of a natural language.

Today, even in working with natural languages we regard the concatenation of sentences to form new sentences (with the help of some copula like and, or etc.) as produced by operators 'and', 'or', 'if, then', which from a logical point of view are considered as two-place operators that combine two given (logical) sentences into a new one, such that, considered as a whole, this new sentence possesses a definite truth value. It is clear that the theoretico-explanatory logical analysis is somehow (mis-)projected as descriptive of (or operative within) the inner process of a natural language. Language does not work in that way, but it can be *analysed* in that way, though not in a global manner and only under restrictive assumptions.

Summing up that part of *BS* which makes up sentential logic one can transcribe Frege's result in the following way:[18]

Axioms:
(A_1) $A\rightarrow(B\rightarrow A)$
(A_2) $(C\rightarrow(B\rightarrow A))\rightarrow((C\rightarrow B)\rightarrow(C-A))$
(A_3) $(D\rightarrow(B\rightarrow A))\rightarrow(B\rightarrow(D\rightarrow A))$
(A_4) $(B\rightarrow A)\rightarrow(\neg A\rightarrow\neg B)$
(A_5) $\neg\neg A\rightarrow A$
(A_6) $A\rightarrow\neg\neg A$

Derivation rule:
R 1: $A\rightarrow B, A\vdash B$

Frege was important in developing predicate logic. In *BS* he introduces a general concept of functions where his mathematical experience may have been essential. He had the idea that it is possible to express the utmost generality with respect to the *truth* of statements/propositions by using the analytical and expressive power of functions (as generalization of the mathematical use the latter). Thus, the introduction of functions amounts to introducing a new means and aspect of analysing linguistic expressions, in so far as the latter refer to or are concerned with the world, i.e. refer to a judgeable content. This method of analysis ought to be considered (with some qualms, of course, cf. G.Patzig vs. J.Lukasiewicz with respect to interpreting Aristotelian logic[19]) as a generalization of the subject-predicate analysis as exemplified by Aristotelian syllogistics.

Logic should—with respect to mathematics—be able to solve problems which hitherto could not be solved. Thus, a sentence such as 'there are infinitely many prime numbers' cannot even be analysed in Boolean logic.

Anyway, the merit of Frege's approach was to be able to exhibit Aristotelian logic as a sort of borderline case (e.g. [3.3], 22–4, where syllogistics is reconstructed).

Usually the sentence 'all men are mortal' is analysed (with respect to subject and object) as '(Bx→Ax)'. The functional analysis is $(\forall x)$ (Bx→Ax) meaning that 'for all x, if x is human then x is mortal'. But according to Patzig ([3.50], 47) there is more to it, since in the Aristotelian case the subject of a sentence is not the universal class of individuals but the class of individuals of which B holds, i.e. the class B. A is the predicate. In Aristotle the 'universe of discourse' is restricted to objects of which B holds.

The Transition from the Logic of Concepts and Functional Expressions (BS) to a Logic of Value Ranges (GGA)

In GGA ([3.11], [3.14]), Frege's main *oeuvre,* which is explicitly concerned with his so-called logicist programme of 'reducing' arithmetic to logic (given his conception of logic), Frege once more formulates his logic (cf. sections 1–48). The main differences with respect to *BS* concern:

1 The introduction of so-called value ranges for functions (see below).[20]
2 Sentences are consistently considered as names for truth (values), i.e. a logic of terms is developed.
3 Syntax and semantics are defined much more precisely.

Preparatory works for GGA ([3.11]) are *Funktion und Begriff* ([3.8]) in which Frege introduces value ranges, *Über Sinn und Bedeutung* ([3–9]), and *Über Begriff und Gegenstand* ([3.10]), which are all generally regarded as already belonging to Frege's linguistic philosophy.

In [3.8] Frege minutely dissects the concept of function (and its generalization) and for the first time introduces value ranges of functions (actually as undefined basic concepts). He also formulates a first version of what later became the notorious Axiom 5 in his GGA, opening up the possibility for the derivation of Russell's paradox. In the introduction to the *GGA* Frege discusses exactly that axiom and its possibilities as problematic.

To pick out just a few aspects which are interesting for shedding additional light on Frege's conception of logic in the later stages of his life, consider the following: Amongst other things, Frege shows how one can get from expressions for functions (remember they are values of the application of a rule of ascription/assignment) to the 'actual essence of a function'. Taking expressions like '2.1^3+1', '2.2^3+2', '$2.4^3 + 4$', one can see

what those expressions have in common, namely, what in the 'unsaturated' (see below) expression '$2\cdot x^3+x$' is present besides the 'x' and what could be written in the following way: '$2\cdot(\ )^3 + (\ )$'.[21] Into the empty slots one can insert names of numbers, such that again, a name of a number is the result. Thus a function by itself can only be *alluded* to but cannot be (literally) denominated.

The expression '$2\xi^3 + \eta$', and thus any *function* ξ,η (which today would be called dummy variables), is therefore incomplete or, as Frege calls it, 'unsaturated', which means it is in need of supplementation.

And it is this property that principally distinguishes functions from objects, or from what, in a model, can play the role of an object. So, if one wants to be clear about what is meant when we talk about an object, one could say that an object is something that can be put into an empty slot in a function, is able to play the role of an argument in a function, is something to which a name can refer.

Only in applying a function to an object does a function yield something independent in itself, namely the value of the function, which again is something that can play the röle of an object or, in Frege's diction, is an object, though this 'is' need not be interpreted in a Platonistic, realistic way but can also be understood as being simply explanatory with no ontological commitment.[22]

Nevertheless it makes sense to say that for Frege the distiction between function and object plays the röle of a basic ontological distinction.

Concepts especially (remember that Frege's starting point are judgements) are considered as special functions, whereas propositions (thoughts) are considered as objects. Thus, the unsaturatedness of functions means that functions are not objects. Any value of a function, however, is an object.

With respect to the plainly mathematical concept of functions it is essential to note that not only numbers are admitted as arguments and values. In Frege's 'technical' language 'truth values' especially are admissible as arguments and values, which means that concepts (technically speaking) can be characterized as specific functions, i.e. as functions whose value is always a truth value [3.8], 15.

Frege therefore insists that we should see how close what in logic is called concept is connected with what he (and we today) call functions. Especially the idea of the extension of a concept, i.e. the characterization of something as 'falling under a concept', can be grasped by the idea of a function (or be realized/actualized in a different way) in a more general way, i.e. as being the value of a function where the concept of 'value range' proves decisive.

We say, for example, that the value of the function $2x^3+x$ for the

argument 1 is 3. As we can see in Figure 3.1 below, we can identify the value range for two functions, which also allows us to talk about equivalence of function (i.e. if they produce the same value ranges).

	argument	0	1	2	3	4	5	6	
$x\ (x - 4)$	value (1)	0	–3	–4	–3	0	5	12	value range (1)
$x^2 - 4x - 2$	value (2)	0	–3	–4	–3	0	5	12	value range (2)

Figure 3.1

REFLECTIONS ON FREGE'S PHILOSOPHY OF ARITHMETIC

With the previous chapters at the back of our mind, we can now concentrate on the definition of numbers. I shall be very explicit in order to convey what it means to give a logical definition and once more shall shed some light upon Frege's concept of logic in general[23]. It is essential here to get a feeling for the formal tools in use, especially the epistemic resolution level provided by them, which I think is distinct from the epistemic resolution level of ordinary language. As background, I shall use primarily *GLA* and *GGA* and discuss the important distinction between sense and reference, into which Frege's *beurteilbarer Inhalt*[24] decomposed in the *GGA* and which is essential for his philosophy of language. I shall also briefly touch upon the so-called Axiom 5 (from the *Grundgesetze,* the principle of abstraction, cf. *Grundgesetze,* pp. 36, 69, 240 and 253 ff.), which led to Russell's paradox with respect to consequences for Frege's programme.

First, I shall try to develop a technical, theoretico-explanatory understanding of Frege's definition of a number, which is deliberately not to be understood in historical terms but rather as an explanatory reconstruction. The picture thus developed should assist in an understanding of how to understand the philosophical significance of Frege's definition.

Frege's starting point in his context of conveyance, i.e. the presupposition he uses to get off the ground in a discussion, is that the realms of application for the concept of number are usually one-place concepts (i.e. predicates), which means that he already presupposes his analysis/ understanding of concepts *as* functions. In short: since one-place concepts can be empty as well, the number zero [0] can be defined as a statement (actually a number statement) concerning an empty concept, i.e. a concept under which no objects fall or belong.

Furthermore, since a concept to which there belongs one and only one

object is definitely distinct from that object, one can consider the number one [1] as the *property* of a concept, and thus primarily not as the property of an object. And if one knows what it means to ascribe the number *n* to a concept, one also knows what it means to ascribe the number *n*+1 to a concept.

Now all this is not as simple as it sounds. An essential presupposition for an understanding of the approach is to have a 'logical picture' of what it means to talk about the immediate succession in a series/sequence of objects (cf. [3.3] *Einiges aus der allgemeinen Reihenlehre*). This logical analysis can be used to make clear in a most general way what the succession of one number to the next one in the sequence of natural numbers amounts to (cf. [3.6], 67, section 55). One can then very clearly express what it means to talk about the ascription of the number *n*+1 to a concept F. From a purely logical point of view it means that if there is at least one object *a* belonging to F, such that one can build the following concept G, defined as 'belongs (also) to F but is distinct from *a*', then the number *n* is ascribed to G; in symbols, the cardinality of G is *n* (card (G)=n).

This construction can be applied to any *a*, even those not belonging to F.[25] Therefore one can define G more precisely as G[*a;* F] and then the following holds: for any *a* from the extension ext(F)=[F] of F it is the case that card (G[*a;* F])=*n*. This means that by using purely logical means, i.e. in the most general way, one has expressed what it means that the number *n*+1 is ascribed to a concept F. And this logical understanding is independent with respect to its claim of validity of any *Anschauung* in the Kantian sense and therefore, as Frege claims, not synthetic a priori but, as he still claims in *Logik in der Mathematik,* analytically a priori.

Let us now informally come back to the case of the number zero: one can choose an inconsistent concept (e.g. $\alpha x\ (x \neq x)$, the concept of all *x* distinct from themselves) and recognize that it does not make sense to consider any object as belonging to that concept—which means that we cannot conceive of the existence of such an object. Now we may consider the 'class of all concepts F which have the same extension as Λ' (I shall write $[\Lambda]$). We assume that there exists a one-to-one mapping between the elements of the extensions $[\Lambda]$ and [F] of the concepts Λ and F, respectively. This mapping defines an equivalence relation between concepts and the class $[\Lambda]$ is an equivalence class of second order and as such an expression of the extension of the concept 'equinumerous to L'. It is only by a detour via this class [L] in its entirety that one ascribes the numeral 0 as a number to the concept Λ. In n: card: $\Lambda \vdash\!\!\rightarrow [\Lambda]$ such that card $(\Lambda) = 0$.

This kind of reconstruction factually corresponds very closely to

Frege's ideas, since his concern is to define the number which should belong to a concept as the extension of the concept 'equi-numerous to the concept F' (cf. [3.6], 79/80).

It definitely does not mean, however, that one needs to count the elements of $[\Lambda]$ or needs to know $[\Lambda]$ in its entirety or to understand, in a plainly logical manner, what is intended by a number. The logical 'intuition' behind all this seems simply to be that one can say someone has grasped what is meant by some number card. (F) ascribed to a concrete concept F, if they have grasped the latter for all concepts with the same extension as F, which means that that kind of grasping is independent of the choice of a special representative as element of $[\Lambda]$.

Now all this talk of 'grasping a concept' (e.g. the concept of a number) is not intended as empirical psychological talk. It rather aims at showing that it is not necessary to be concerned with philosophical introspection (or, for that matter, a private language) in order to grasp what in general is meant by a number. What is claimed is that this kind of grasping is independent of the special choice of an empirical visualization/intuition (in Kant's sense of *Vorstellung*), or of an empirical ability to understand mathematics.

Let us return to zero and consider the transition from 0 to 1. If one wants to understand Frege's approach, one has to try to recognize something as succeeding immediately upon zero; something which will be able to play the röle of 1. Frege uses a one-place concept (a predicate) '$\psi(x)$' defined as ψ := 'equal to 0'. But since 'equal to 0(0)' holds true of 0, we can see that 0 belongs to ψ.[26]

Consider the concept 'equal to o'. This does only mean that some object 1 immediately succeeds upon o. One can then determine that 1 is the number which belongs to the concept 'equal to 0'.

Counting thus is reduced *qua* logical understanding of what is going on to a simple procedure of ascription *f*, contrary to an introspective understanding of how one personally perceives oneself in the process of counting—how one actualizes counting—or how one tries to teach children to count properly.

Presupposing Frege's functional interpretation or rather reconstruction of the idea of a concept, a number is attached to a concept in the sense that the objects which need to be counted fall under (belong to) that concept. (The objects are put together under a concept. The number attached to the concept is itself an object in two ways: first, as a sign to which we are accustomed, i.e. as something we have learnt to manipulate; second, as an abstract object such that any kind of realization/actualization will help us to use the abstract concept (of number) correctly.)

What seems important is the logical step of abstraction that is explicated by Frege's analysis. Already in his habilitation/second

dissertation ([3.2], 1) he is concerned with a similar problem concerning measurements of length. Length should no more be considered as some kind of 'matter' filling up a line between its starting point and its end point. This means that what is important (in modern terms) is solely the beginning and end point and the attachment of a value, as was later clearly elaborated by Hausdorff, Frêchet and others[27], when they were defining distance 'functions' d(a,b), if a and b designate points.

One clearly sees how Frege is against 'introspection' as an intuitive (visualizable, *anschaulich* in Kant's way of talking) source of logical knowledge and how he, despite remaining extensional in his logical outlook, is able to grasp what goes on in mathematical thought, considered as an abstractum.

Frege therefore insists, for example, that the number 1 assigned to the concept 'moon of the earth' does not express any content about the moon, but only means that there is just one object falling under the concept, no statement about the moon as such.

The role of abstraction in the process of counting becomes clear in the following way: corresponding to a concept (but not identical with it, it should be considered rather as a replacement or expression of a concept) there is the extension of a concept, a sort of class of well-defined objects (at least considered in that way) belonging to that object. Counting amounts to identifying a concept F such that the objects to be counted fall under this concept (considered as a function!) and then to ascribe a number to that concept; a function $f(x)$ is actualized as card (F).

The intuition explicated by Frege consists of the idea that what counting *amounts to* is the fact that one subsumes the objects to be counted under a concept (remember this talk is to be understood interpretatively or explanatorily and is not literally descriptive) and then one can say that to the so identified concept there belongs that number which we in our practice regard as the result of a process of counting, or have learnt to generate as such.

Now if one thinks that this is really essential for a theoretical understanding of the idea of number, then it is good for a start to be clear about what it means that no number belongs to a concept or further, that there is exactly one object falling under a concept. This is exactly what we said before, namely that one formulates a logical analysis about what it means, e.g., that no object belongs to F—but need the extension of the concept be given literally?

According to Frege, numbers are (simply) objects and not concepts, i.e. they should be regarded as arguments in a function and one should be able (logically speaking) to quantify over them.

In order to be able to define numbers as objects in a logical sense, Frege invents what today is called definition by abstraction. In [3.6], 74 ff. he

illustrates his idea by the transition from the concept of two parallel lines to the concept of the direction of lines in the Euclidian plane.

In principle, such a definition by abstraction (generation of equivalence classes) works in the following way:[28] one starts with a basic domain B of some kind of entities one is intimate with and of which one has practical experiences. It should be possible that one is able to experience there the fact of a real partition of that domain, i.e. of subclasses/aggregates of objects consisting of elements of the original domain, which under a certain aspect of consideration, i.e. *modulo* this aspect (which means by disregarding other distinguishing features), are considered as equal, i.e. identical with respect to some value of a function, or indistinguishable for a certain aim, demand, application or whatever one wants to do with these entities.

Consider again the set of parallel lines (replaced by 'lines of the same direction' in *GLA*) in the Euclidean plane (here the basic area B) or perhaps a set of small wooden blocks for children, which can be distinct in size, thickness, colour, roundness, etc., such that only length is the essential aspect to choose in order to regard them as equal or not (cf. Frege's Habilitation).[29] If one wants to generate an object with the length of, say, 7 units and considers two groups of objects of length 3 and 4, respectively as characteristic length, then it is inessential which special representatives of the corresponding groups one chooses and places together such that the length of the concatenation will be 7 units.

The point in question, which leads to definition by abstraction with the help of equivalence classes, is exactly the explication of just that procedure, i.e. the steps of abstraction involved, a procedure that does not rest upon introspection or upon an intuition built upon inner perception.

Abstractly speaking, this means that one assumes the existence of an equivalence relation 'R' between the elements of B (in our case, identity or indistinguishability with repect to some evaluation) in that domain.[30]

One can define such equivalence classes [x] as the sets of all those elements y which are in relation R to some chosen *x*, i.e. by setting [x] := {*y*/ *x* R *y*}. [or written as {*y*/*x*~*y*}].

In this way one can attach to each element *x* from B a (new abstract) object [*x*] (from M). One can understand this especially as a mathematical function

$$\mathbf{f : B \rightarrow M;\ } x \mapsto \mathbf{f}(x) = [x].$$

This means that the elements *x* and *y* are in the relation R [*x* R *y*] if and only if they are assigned the same 'value' f*(x)*=f*(y)*, i.e. *x* R *y* : <=> f*(x)*=f*(y)*, i.e. if and only if [x]=[y]. The relation R thus induces a partition of objects in B.

The result is that one can choose a more or less abstractly distinguished or even constructed set of objects as a replacement of some concretely chosen realm B and use the replacement to talk (simulatively) about the situation, relations and concerns in the original realm B. This is, more or less, the theoretico-explanatory understanding underlying Frege's whole approach as it is used today in many areas of mathematics (definition by abstraction).

As a point of departure for his construction, Frege chooses the concept 'equinumerosity' of concepts, i.e. as an equivalence-relation upon some realm containing concepts referring to some realm of effective experience. Equinumerosity is constructed as a one-to-one mapping between the objects falling under some concepts F and G, respectively. For tactical reasons I use [F] as an abbreviation for the equivalence-class of all the concepts with the same extension as F, such that [F]:= $\{G/F \underset{R}{} G\}$. This class [F] is then mapped onto card (F). If one introduces the mapping 'card', i.e.

$$[F] \mapsto \text{card (F)} : = \{G \text{ / F equivalent to } G\} = [F],$$

One can say that

> F is equinumerous to G if and only if card (F)=card (G)

In the *NL* paper *Erkenntnisquellen der Mathematik und der mathematischen Naturwissenschaften,* Frege retrospectively writes:

> The disposition to produce *proper names not corresponding to any object* is a property of language that proves disastrous for the reliability of our thinking. If it happens in the context of art or literature where anybody knows that they are dealing with literature it does not lead to disadvantages… An especially remarkable example however is the creation/formation of a proper name following the pattern of '*the extension* (Umfang) *of the concept F*', e.g. in the case 'the extension of the concept fixed star'. This expression seems to designate an object because of the use of the definite article 'the'. But *there is no such object which in a linguistically correct manner could be designated as such* (i.e. as literally corresponding to the expression). From thence the paradoxa of set theory developed, which killed this set theory. I myself have been deceived in that way as well, i.e. when I tried to produce a logical foundation for the numbers, *in so far as I wanted to conceive of numbers as sets*[31]
>
> ([3.19], Vol. 1, 288, my emphasis)

It surely was the use of classes/value ranges within logic (i.e. quantification over value ranges) that actually paved the way for the

possibility of the derivation of Russell's paradox by using the abstraction principle (cf. [3.11], [3.14] and addendum: 253).

Perhaps one should pay attention to some minor points in *GLA* and not only to the fact that Frege in *GLA* still uses his old conception of 'judgeable content' (to which correspond *BS* expressions, i.e. concept-script expressions as logical analysis of ordinary language expressions), which later, due to the introduction of sense and reference, decomposed into 'thought and truth value'.[32]

First, however, one might explain the intuition in order to grasp the concept of number in the context of a general strategy and try to make available the meaning of abstract knowledge by means of using our logical/analytical abilities. This makes the claim of 'general validity' (*Allgemeingültigkeit* or general truth) of knowledge (cf. Kant) a matter of controlled reproduction and therefore to be generally obligatory even in thinking of ethics.

The intuition is that one thinks that one has understood or grasped what, e.g., the number 'three' amounts to if one has grasped the equivalence class of sets of three elements each. This means that speaking of 'three' can be represented by a set of three elements.

In the *GLA* definition this is chosen in such a way that the 'number of F' [card (F)] is defined by means of the extension (used as an undefined basic concept) of the concept 'equinumerous to F(X)'.[33] But 'equinumerous to F(X)' can be given by an equivalence-class of concepts:—what does it amount to to talk about someone having grasped the concept of number or at least of having grasped what it means to detect that a certain quantity of objects belongs to or falls under a concrete concept F*?—independently of the special choice of a concrete concept (a special representative from the repertoire [F]), one can always decide whether F* belongs to the extension of 'equinumerous to F', which means that there is a G from [F] such that G is equinumerous to F*, i.e. one should be able to ascribe the correct number to F*.

Actually, one explains the behaviour of a person in the process of counting by saying that this person needs to have grasped the equivalence class [F] (in one go, so to speak) and by providing a necessary condition (as the 'condition for the possibility of knowledge' in the Kantian sense) which (theoretico-explanatorily speaking) needs to be actualized in order to be able to count.

Now all this may sound extremely complicated and hardly any one will claim that they have learned to count in just that way. One of the problems in philosophy of science is that we look for (universal) explanations which at the same time can be understood as descriptive, i.e. as (even introspectively) action-guiding, even if they are not. So the problem of 'grasping' in our case the meaning (here sense) of numbers by

grasping the equivalence class [F] in one go may lead to a lot of basic empirical misunderstandings in ordinary-language reception. Of course, in philosophy one has the impression that one seeks a theoretical understanding (e.g. of numbers) that just allows for a descriptive projection into ordinary language, without doing much harm as long as we stick to ordinary realms of experience. But sometimes we need to be able to see those misapplications and be able to correct them—provided we do not presuppose some universal, god-given, pre-established harmony between language and the world. Frege paved the way for stepping out of (a universal) language. A diversity of local language games, which are not to be considered as language-relativism, may be a good thing to which to remain alert, i.e. sensitive to reflective correction and prepared to overcome the problems just hinted at, without, however, falling into the traps of scepticism.

So again, all this may sound extremely complicated and again hardly anyone will claim that they have learned to count in that way, but that is not the point. Actually one only expresses what (theoreticoexplanatorily, i.e. from a logical point of view) it means to say of someone that they can count. The real problem is whether this theoretical explanation is close enough to our everyday understanding to be helpful.[34]

So the point is that our theoretico-explanatory talk must not be projected in an action-guiding way upon reality/experience, i.e. it must not be considered as a description of our effective actions or thinking. Otherwise one would really have to be able to grasp the whole class [F] in one go and for all times. In principle there are many actions which may be compatible with one theoretical explanation.

In this context a short discussion of Frege's distinction between sense and reference may be of interest.[35] In the sequel I shall use the special expressions F-sense (F-*Sinn*=Frege-*Sinn*) and F-reference (F-*Bedeutung*=Frege-*Bedentung*) for Frege's special use of them.

Frege uses a discussion of claims of equality (as different to the position in the *BS*) to introduce the distinction—between sense and reference as two technical/theoretical components for the determination of meaning (as the general expression for an undifferentiated understanding) of linguistic expressions.

I shall here try to link up with the former discussion, especially the relevance to build equivalence classes. A very good discussion of the technical reasons for introducing the distinction between sense and reference in the transition from the logic of the *BS* to the logic of the *GGA* can be found in [3.46]. A discussion that links the logical and the philosophical aspects from a philosophical point of view can be found in Stekeler-Weithofen ([3.56], 272), whose approach I would like to adapt and modify.

The F-reference of a name is the named object.[36] Truth values as F-references are therefore attributed to the 'sentences' in logical concept-script-notation (expressions of a logical analysis, eternal sentences). The F-sense of a name or a sentence consists in the way (of being given) in which the F-reference of a sentence is determined, i.e. the reference of a name towards an object is mediated by the F-sense. Thus: a sign *expresses* its F-SENSE and *designates/gives/provides* its F-REFERENCE.

One can understand this in the following way: in the realm of the names (anything that can act/work as a name in some distinguished realm) the F-sense stipulates an *equivalence-class* of names with the same 'F-reference'.[37] The sign 'morning star' expresses its F-sense (F-*Sinn*) (i.e. the way of givenness of the object Venus, e.g., as morning star) and assigns (literally gives to us, provides us with) its F-reference (F-*Bedeutung*) (i.e. designates the object 'Venus'). The expression 'the number of children in this room' thus designates, e.g., the *number 3* and it *gives* '3' as an application of the *concept* 'children in this room *(x)*'. Expressions with the same F-reference thus should allow for a replacement *salva veritate*.[38]

In grasping the sense-component of the meaning of a linguistic expression, as it should show itself (explanatorily speaking) in the grasping of the corresponding equivalence class, first of all the so-called 'context' (of knowledge) is brought in. Thus, with the help of the mediating rôle of sense in determining the reference, it becomes clear how it is possible (i.e. in which way it is meaningful or in which way one can talk about it meaningfully) to refer to an object unambigously (in so far as it is an actual object), even without knowing the object as such.[39]

Anyhow, one can explain what it means to say that there is attributed one and only one truth value to a sentence without knowing which value that may be. Of course that does not mean that this is possible in all contexts (cf. intuitionistic or constructive mathematics today).

Frege's logical investigations are quite often of a theoretico-explanatory kind, as I have tried to emphasize several times. But many of his papers (like 'Sense and Reference' [3.9]) seem to deal with the context of the so-called ordinary language, though he just uses it to introduce technical terms with the help of nice-sounding commonsensical names. In understanding the philosophical consequences (depending on the aim of the philosophical investigations) one should also do justice to the technical meaning and not purely the commonsensical reception of expressions like 'sense' and 'reference'. Still, the philosophical interests in the latter have proved

fruitful, even though sometimes they are put out of context and seem to have gained a life of their own.

Understanding the theoretico-explanatory moment of Frege's idea of sense can help us to focus not just on questions concerning the meaning of linguistic expressions in the 'ordinary language context', but also to take into account some constructive elements of, say, ascending definitions of concepts ([3.19], vol. 1, 217–72). This can help to counter the tendency to universalize common sense and to correct dogmatisms of any given time. It can help to produce flexibility and adaptability to new situations and positively influence and balance the interplay between science and common sense—ordinary life. Frege himself explicitly emphasized that talk about numbers is talk concerned with content. The constructions used to grasp the sense of mathematical expressions or claims are not literal descriptions of what one thinks if one uses certain words. Meanings usually are not given literally. The constructions used are 'objects of comparison' which surely need to be supplemented by some 'approximation from within' the actual use of language. But only the interplay between both sides can lead to a rewarding 'reflexive dealing' with some realm of objects.

REMARKS CONCERNING THE CONTEXT OF FREGE'S PHILOSOPHY OF LANGUAGE

One starting point for an approach to Frege's philosophy of language can be the question, 'how one could talk or communicate about abstract entities/objects in such a way that one can understand what abstract objects are' and also in such a way that one can *handle* those objects (so to speak) reasonably.[40] This presupposes an evaluation by both common sense and scientific understanding and furthermore a connection between both, since via his prose, even a scientist uses common sense when making sense of his findings. If one poses the question in such a way, one clearly has a picture, a sort of understanding, in mind of how language actually works.

It is to Michael Dummett's credit that he has focused especially on the linguistic interests of Frege's *oeuvre,* i.e. the philosophical origins and consequences of Frege's philosophy of language, and thus to have led to philosophy of language, although his presentation or emphasis is controversial and not everyone wants to follow in his footsteps.

Dummett emphasizes the rôle of the so-called 'context principle', which, roughly, says that only in the context of a sentence does a word have a proper meaning, and thus contradicts any understanding of Frege

that elaborates his conception of language as naive and as simply a picture of the world.

The context principle plays an important part in Frege's *GLA:* 'to fix the…conditions of sentences in which numerical terms occur'.[41] In the *GLA* it is finally quoted in [3.6], section 106, 'to remind the reader of an indispensable step in the preceding argument' ([3.37], 200). The consequences of the context principle for the philosophy of language, i.e. the consequences it has for our modern understanding of language and thus for our 'understanding of meaning', leads towards a 'truth-functional semantics', i.e. one needs to know the truth conditions of sentences containing 'expressions of interest', i.e. expressions, whose meaning we want to grasp.[42]

The context principle can be used and applied in this sense as a theoretical starting point to produce a modern, linguistically orientated reconstruction of Frege's philosophy.

There is another sense in which the significance of Frege's 'semantic theory' can be viewed. Truth-functional semantics can be used only as the result of a technical necessity to understand the meanings of the parts of sentences from *outside* (by way of meaning partitions of sentences) because in the course of logical analysis and reconstruction of the sentence one has attributed exactly one truth value to the sentence as a whole. This does not mean that the extension of the context principle is wrong or unimportant; the aim is rather to focus, in a stronger sense, on Frege's anti-psychologism and the possibilities for a non-introspectivistic philosophy, a philosophy not resting upon psychological abstraction, in contradistinction to Husserl who might be interpreted in this way.

The problem especially concerns the discussion about the determination of the domain of reference of some language—talking, for example, about abstract objects. Dummett writes: 'there *is* a further question to be settled, especially when a term-forming operator, and therewith a whole range of new terms (or items/entities), are being introduced: the question of suitably determining the domain of quantification,' [3.37]. This, however, argues Dummett, was 'persistently neglected [by Frege], a neglect which, as we shall see, proved in the end to be fatal' (Ibid.).

Stekeler-Weithofer puts this straight in arguing that Frege was shifting to and fro between two incompatible points of view:

> (1) that the universe of all objects of speech be pregiven such that (e.g.) the meaning of equality has (already) a fixed/precise/ ready meaning and (2) that the meaning of a name be given purely by its use within sentences.
>
> ([3.56], 272)

The problem concerns the constructive character of Frege's means of expression—his language, i.e. its characteristic of being constitutive for objects both in the case of the abstraction principle and in the case of the talk of equality.[43]

If not for reasons of defence, at least to put matters straight, one should point out the fact that Frege again and again is wavering between a mathematical use of language, between mathematical practice and its projection onto commonsensical matters. This holds especially for originally logico-technical concepts like sense and reference, which only later (in the context of introducing the terms and giving examples from ordinary language to show their applicability and importance) gain an enormous significance for philosophy of language.[44]

Later in his life Frege was well aware of this fact of language division. In his posthumus paper concerning 'logics in mathematics' (cf. [3.19], 1:219), Frege explicitly talks about a distinction between technical terms and commonsensical expressions. In this context, one could talk of a sort of 'split semantics' ([3.28] and [3.29]), which Dummett somehow seems to admit when he writes: 'The language of the mathematical sciences differs markedly from that of everyday discourse: it could be said that the semantics of abstract terms bifurcates, according as we are concerned with one or the other' [3.37].

Phrased more generally, our problem is the *constitution of objects* by means of using a language—considering Frege's experience and background as a mathematician, one can interpret his findings in the following way. Frege provides us with a theoretico-explanatory analysis of how language works, an analysis which then is compatible with several concrete and effective procedures to determine, e.g., a 'domain of quantification' (a favourite problem in modern linguistically orientated philosophy—'To be is to be the value of a bound variable' [3.52]).

Expressed, however, in Kantian terms, i.e. in the way that is relevant to Frege considering his philosophical background and upbringing, one could say that Frege tried to formulate the 'conditions for the possibility of determining the realm of reference (the [logical] domain of quantification), or in a more modern way: giving formally determined *necessary conditions* for just that. In interpreting and trying to understand Frege, one has to take into account the language of his time and his background of experience, and therefore need not take everything too literally when viewed from a modern understanding of language.

Considering the determination of the reference of 'numbers', it is, from a mathematical point of view, essential first to state/identify the formal properties that must be fulfilled by something that should be able to work as a number (presupposing that they link up to our ordinary intuitions or those of the mathematicians, just in case one wants to reconstruct those

intuitions).[45] Afterwards, say after the definition of 'zero', some entities—quite often not a single object—will be presented in a way that the possibility is formulated as to how to identify and use something as 'zero'. One more or less keeps an open mind about what might be expected as a definite determination of a realm of reference.

Dummett is concerned with this in so far as he writes:

> On the *Grundlagen* view, we can ask whether the truth-conditions of sentences containing a term of the kind in question have been fixed, and (we can ask) for a statement of those truth-conditions; *we cannot ask after the mechanisms by which the truth-values of those sentences are determined, nor, therefore, after the rôle of the given term in that mechanism*.
>
> ([3.37], 207, my emphasis)

The aim of a logical definition (e.g. of numbers), however, should be that it should hold in any possible world (as it is usually attributed to Leibniz and taken up by Frege), which means it should be *independent* of the *special choice* of the *mechanisms* for the determination of the truth value of a sentence containing a word for designating, so to speak, a number.

This also means, however, that it is enough to know one single counter-example, one single concept, such that there does not exist a mechanism to determine whether an object falls under the concept, to quash the claim for utmost generality, i.e. for universal logical validity.

Now if one presupposes that in demanding (Frege's proposal) to start logic with 'judgements'[46] means that a sentence (as a whole) gets attributed a truth value and that one determines 'meaning' starting from the outside, with the surface, so to speak, and not by abstracting from introspective experiences, i.e. by decomposing a sentence into meaningful components (only in the context of a sentence do words have a meaning/reference), then one can understand this matter in the following way. One expresses only what it means (theoretico-explanatorily speaking) to talk about a word having reference, what it means to ascribe some reference to a word, but still has to determine or define the truth conditions for the sentence containing the word in question. So one (might) know that it should have some reference but has not yet specified it. One knows what it means/amounts to look for some reference, but one still has to determine compatible mechanisms, which may be context-dependent and which attribute the truth values by way of judgement.

This can either (wrongly!) lead to projecting the theoretico-explanatory structures onto the world, i.e. turning them into effective procedures, as it is sometimes the case in classical philosophy—although there 'theories'

tend to be rather introspective-abstractive. Alternatively, one can deal with unreflected (?) skills, which are then considered to make up for the effective use of some language.

According to Frege, the distinction between sense and reference can be extremely important, especially in the context of philosophy of language, in so far as on the one hand it can help to systematize the referring habits of human beings in a theoretico-explanatory way. On the other hand, this distinction can, if it does not just project a theoretical understanding, help to take care of the actual mechanisms to fix the reference of the expressions of something used as a language. These actual mechanisms stand in contradistinction to those one seems to *use* consciously (or one appeals to), and which enable one to keep in mind those many facets of understanding and communicating 'meaning' (in a modern sense) that seem to be relevant today.

REFLECTIONS ON THE CONSEQUENCES OF FREGE'S WORK

Apart from perhaps the second section in this chapter, I have placed the emphasis on the philosophy of logic because I think that the other important aspects of Frege's work, such as the philosophy of mathematics or the philosophy of language, become more or less self-explanatory if one has a clear picture of Frege's conception of logic. This, however, is not true of the history of Frege's influence, especially if one tries to distinguish between a logical or objective core of Frege's philosophy and its reception.

Though many of Frege's ideas, for example, his notation of logic, were taken up and transformed outside Germany (by, for example, Jourdain and Russell) he might have suffered a fate similar to Wittgenstein with regard to Austria. Perhaps the best-known influences and effects of his work can be found in 'analytical philosophy', of which he has been considered the 'grandfather' by Dummett (with Wittgenstein as the link between).

I shall now leave the well-trodden paths of traditional analytical philosophy and consider Frege from a meta-philosophical point of view. In doing so, I shall closely analyse Frege's anti-psychologism.

Let us presuppose that one can interpret/reconstruct Frege so that we can say that it was his aim to gain access to an *understanding of the meaning* of mathematical or of abstract knowledge in general. Furthermore, this access should not be considered to *rest upon* synthetical (empirical) sources of knowledge and especially not upon some introspective perception.

In order to do this, one tries to make use of an analytical source of knowledge, which, in the Kantian sense, should also produce the

justification of something as knowledge. Thus, one could interpret Frege's approach as a new method, or rather, way of reflective thinking, leading to a new kind of actualization/realization of an essential act of philosophy, namely the provision of a possibility for a *correction of knowledge by reflection* with the help on an analysis of meaning. In other words, Frege's approach would lead to a literal understanding of how knowledge comes/is brought about.[47]

With respect to a reconstructive interpretation, i.e. trying to make sense (of Frege's approach) within a modern perspective (on philosophy) and with hindsight (of the experiences of this century), we simply cannot abandon, these considerations and presuppose an understanding or perhaps conception of philosophy that is at least twofold (see below) and definitely goes beyond the idea that even modern philosophy is nothing but footnotes to Plato:

1 In our thinking about and in viewing the world, we have to do justice to philosophical attitudes in attributing an important quality to them, namely that philosophical thinking should help us reflectively to correct mistakes and guide our view towards possible solutions if we are stuck; i.e. if we do not know how to go on (in Wittgenstein's sense).
2 This means that one presupposes that occasionally we can be deceived (or experience being deceived), that we can have the insight into mistakes and the experience of errors and again, at least occasionally, we can reduce these experiences to the fact that in some cases in our behaviour we are misguided by some false picture or wrong sort of information about the world.

But it is exactly the second point which already presupposes some sort of explanation (eventually leading to a locally applicable theory) why and how some behaviour in others and ourselves, experienced as a mistake, came about. It aims at a reflective correction (of both the theory and the behaviour) in trying to correct the cause (the picture in use).

Loosely speaking, in developing such a (reflective) theory, we will eventually turn it into 'effective use', i.e. the theory will be projected upon the level of individual acting and finally will be activated in an action-guiding manner.

At the level of daily life there may turn up philosophically motivated but individually coloured questions. These questions about the pictures that (might) have seduced us (in our actions) will have a rather constitutive character and, if we want to talk about them consciously, it will be unreflected skills (classified as such from 'outside') which guide our behaviour; skills that may be replaced by other, more successful or effective ones according to the tasks we have to settle. If those skills are

reflected they will become effective, i.e. can be 're-' followed/ re-instantiated consciously.

On the other hand, one can characterize the (research?) programme of classifical/traditional philosophy quite crudely as 'philosophical reflection'—whether at a theoretical level or in the context of daily life. In any case it takes 'inner perception' as a point of departure. This is the situation when one asks to *understand* the content of some 'message', of something intended for communication. Then it seems to be essential to understand what it is that is 'meant'. If one asks 'what is actually the case?' (if one is insecure) one is more or less said to be trying to grasp the truth by getting behind the screen of the appearances, trying to tear (away) the veil hiding reality from our view (to use the old metaphor).

But the aim of this enterprise (whether conscious or not) was to provide knowledge for *correcting* mistakes, so that explanatorily one might speak of corrective reflection.

Especially with respect to logic and the coming about of mathematical knowledge, Frege seems to reject a plainly introspective-abstractive access to an understanding of the content of the meaning of arithmetic or, more generally, abstract knowledge (given the interpretation proposed in this article). For an understanding of the so-called content of arithmetical knowledge, Frege presupposes an 'analytical source of knowledge', which in the case of arithmetic should accomplish what in the the case of the 'psychologistic logicians' was achieved by the use of 'inner perception'.

Frege's method can now be regarded as having consisted in providing the general core (meaning), resting on objective thought, of 'abstract/ mathematical entities' by using a 'logical' (i.e. a concept script) analysis (presentation). Frege tried to achieve it by cutting up 'truth' *(from outside so to speak)* and building up meaning (understanding the content of an expression) externally, by realizations in a model, as one might say today. This procedure of building up meaning should help to make *accessible* (in a controlled and reproducible way) the meaning of abstract concepts (of mathematics), which leads to the problem sometimes called 'paradox of analysis'.[48]

Given this understanding,[49] the problem is now how fruitfully to apply Frege's methodology to the 'reflective' concern of modern 'philosophical thinking' as described above, thus getting from the so-called 'What is (really the case)?' question and the question, 'What can I know?' to the more promising questions, 'What can I understand?' and 'How (depending on the language in use) is understanding brought about?'

This last question is important for the 'coming about' of an'understanding of scientific knowledge', in which abstract

knowledge plays an essential part, especially so with respect to 'reflective corrections' in the context of the application of science and technology.[50]

Frege's approach can now be understood (with respect to interpreting the consequences of his work and taking care of some misunderstandings and the historical context of his achievements) as pointing towards a new way of dealing with reflection; a new way of *actualizing* reflection.

Occasionally one has equated this approach with a purely 'logical analysis' of language, an interpretation which some of Frege's remarks at the end of the introduction to *BS* somehow seem to support.[51] The question should rather be 'How can the task of "reflective correction" be met by or, methodologically speaking, be instantiated by linguistic analysis?'

I think one can credit Wittgenstein with having executed the turn to linguistic analysis as a philosophical programme, though the method needs some elaboration or maybe improvement (given the road to linguistically orientated analytical philosophy).

A very good analysis concerning the connections between Wittgenstein's *Tractatus-logico-philosophicus* and Frege (primarily with respect to logic!) can be found in Stekeler Weithofer ([3.56], 248).

The *replacement* of the reflective-abstract method assumed to be characteristic of the primarily classical/traditional approach in philosophy as, for example, demonstrated in Husserl, by the method of *linguistic analysis* (as demonstrated by the 'Wittgenstein of the Philosophical Investigations') leads to a *replacement* of Frege's 'concept script' analysis of 'expressions', produced by using and thus provided by the 'objective' language of *BS*, by a meaning analysis within ordinary language.[52]

This kind of replacement of the original Fregean approach can now, as a system of rules for its use, be followed up on its own as a new programme for doing philosophy. Today, though, one sometimes has the impression that the programme serves just 'as an end in itself'. Not only the general context and aims of philosophy but also the connection to Frege's original aims, and thus to the idea of Wittgenstein's theory of names as a reaction to Frege (cf. [3.58]), have been lost from sight.

The possibilities of newly actualizing the reflective task(s) of philosophy with the help of an analytical approach, especially in the sense of Wittgenstein's later philosophy, are not yet exhausted. Though we have to keep in mind that in comparison with the traditional (introspectively abstractive) approaches these possibilities are just one-side-of-the-coin 'philosophy' and must not be treated dogmatically, i.e. be taken as an absolute method for pursuing philosophy (just as on the other hand,

performing philosophy in the traditional way sometimes gives that impression).

I think that today, perhaps more than ever before, it is essential to take into account the interplay of both sides, analytical and traditional philosophy, science and everyday-life, analysis and tradition, because otherwise we—considered as flies in Wittgenstein's famous picture—will definitely not be able to find our way out of the fly-bottle and will perhaps end up on a Möbius strip[53], the prototype of a 'single or just one-sided surface'.

NOTES

1 Cf. [3.36], (11–12) and [3.37], 111.
2 Cf. [3.53] and [3.54] for the use of 'functional', cf. [3.47], 47.
3 Repr. in [3.24], 1–49.
4 Repr. in [3.24], 50–83.
5 Repr. in [3.19], 2:275–301.
6 The *GGA* contains decisive developments with respect to Frege's logical ideas, i.e. the introduction of value ranges and the distinction between sense and reference (first introduced in *SB* [3.9]).
7 In doing so, I follow the rather technical presentation of Frege's achievements in [3.46] fairly closely.
8 I use the term 'epistemic resolution-level' for this phenomenon and it may be interesting that Frege was befriended by Ernst Abbé who developed the formula for the resolution level of microscopes (working with Zeiss) and that Frege did use the metaphor of the microscope in the introduction of the *BS* [3.3], xi and later in *SB* [3.9].
9 Cf. the problem of the *Paradoxon der Analyse* as discussed in [3.49], and in [3.35] and [3.37], 141. This paradox concerns a fundamental difference about the basics of traditional and analytical philosophy, which can be illustrated aptly with a comparison between Husserl's and Frege's.
10 I refer to his 1914 paper 'Logik in der Mathematick' in [3.19], 1:219–72, esp. p. 277.
11 Cf. Frege's dealing with Boole in *Boole's rechnende Logik und die Begriffsschrift* (1880/81) in [3.19], 1:9–52 and *Boole's logische Formelsprache und meine Begriffsschrift* (1882) in [3.19], 1:53–9.
12 As an example take the sentence There are infinitely many prime numbers, i.e. to each prime number there exists a greater one.' This sentence could not be analysed in classical logic nor in Boolean logic either.
13 To consider a sentence as a sentence means to regard it under a special aspect, i.e. not to consider the content of the sentence as such but solely whether it is true or false (as a sort of attributable property of a sentence, i.e. if an expression is classified as a sentence).
14 I mention that particular sign combination here but the use of quotation marks as a metalinguistic way of talking 'about' was not known to Frege, although there are hints in a later paper, *Logische Allgemeinheit* (not before

1923) [3.19], I: 278–83; esp. p. 280, where he uses the expressions *Darlegungs- und Ililfssprache*.

15 'Der waagrechte Strich, aus dem das Zeichen "⊢" gebildet ist, verbindet die darauf folgenden Zeichen zu einem *Ganzen* und auf dies Ganze bezicht sich die Bejahung, welche durch den senkrechten Strich am linken Ende des waagrechten ausgedrückt wird' ([3.3], 2; my emphasis).

16 'Was auf den Inhaltsstrich folgt, muß immer einen beurteilbaren Inhalt haben' (Ibid.).

17 That seems to be the prevailing interpretation, e.g. [3.46], 24.

18 [3.46], 14.

19 Cf. [3.48] and [3.50], Figs 2/3.

20 [3.11], 15: 'Die Einführung der Bezeichnung für die Wertverlaufe scheint mit eine der folgenreichste Ergänzung meiner Begriffschrift zu sein' (From the way in which we talk about abstract entities it can follow what abstract entities are for us, what they mean, how we should treat them).

21 It is interesting to see that Frege himself here already uses quotation marks in the modern sense and therefore shows an intuitive understanding of the difference between object language and meta language.

22 An ontological problem arises: Is it possible to understand 'is' just in an explanatory manner?

23 One needs to get a feeling from the definition to understand what he means by logical.

24 Judgeable content.

25 If *a* is not element of ext(F), then G[*a*:F]=card (F) or *n*+1 according to our presupposition. We will need that below in connection with Russell's paradox.

26 0 is an element of [ψ] or rather [equal to 0[(X)], the extension of the concept ψ. But 0 is not an element of [equal to 0].

27 [3–39], [3–40].

28 Taking up an idea from *Mathematik in der Logik,* I would like to call these definitions 'ascending' and not 'constructive', as the term *aufsteigend* is sometimes translated in this context.

29 [3.24], 2: esp. p. 51.

30 The formal conditions for an equivalence relation are: if *a*, *b* and *c* designate elements of B such that the relation may hold between them, then the relation R [*a* R *a*] obtains between any element with itself: '*a* R *a*' (reflexivity), further: '*a* R *b* implies *b* R *a*' (symmetry) and last but not least: '*a* R *b* and *b* R *c* imply *a* R *c*' (transitivity).

31 'Eine für die Zuverlässigkeit des Denkens verhängnisvolle Eigenschaft der Sprache ist jhre Neigung, *Eigennamen zu schaffen,* denen kein Gegenstand entspricht. Wenn das in der Dichtung geschieht, die jeder als Dichtung versteht, so hat das keinen Nachtei.... Ein besonders merkwürdiges Beispiel dazu ist die Bildung eines Eigennamens nach dem Muster *"der Umfang des ßegriffes a"*, z. B. "der Umfang des Begriffes Fixstern". Dieser Ausdruck scheint einen Gegenstand zu bezeichnen wegen des bestimmten Artikels *aber es gibt keinen Gegenstand, der sprachgemäß so bezeicbnet werden könnte*. Hieraus sind die Paradoxien der Mengenlechre entstanden, die diese Mengenlehre vernichtet haben. Ich selbst bin bei dem Versuche, die Zahlen logische zu begründen, dieser läuschung unterlegen, *indem ich die Zahlen als Mengen auffassen wollte*'. [3.19], 1:288, my emphasis, I have deliberately produced a very free translation here!)

32 The picture or idea that sentences are ascribed a truth value as their *Bedeutung*= 'reference' will then be projected upon our natural language and eventually leads to a holistic conception of the *meaning* (*t* can be instantiated as reference/*Bedeutung* or sense/*Sinn*) of sentences and finally to the context principle in determining the *Bedeutung*/reference of expressions by decomposition.
33 I sometimes deliberately use the language of functions to highlight the theoretical, i.e. functional, understanding of concepts.
34 It is definitely helpful if we want to construct computers and if we want to be clear about ascribing the ability of counting or computing to them. But even there the physical operation is quite distinct from our way of talking about or ascribing some property to it. What may be interesting, however, is whether a certain mental disposition or attitude may be helpful if we interact with machines, i.e. if we want to handle them, if we want to use them appropriately—whatever that may be.
35 Explicity introduced in [3.9] but indicated already in [3.8].
36 Name is here considered as attributed 'value' like f*(x);* an object *x* being something that can be an argument in a function.
37 To such a class can be attributed a truth value. All this does not concern indirect speech!
38 Cf. the famous Leibniz principle (e.g. [3.6], 76 ff.).
39 Remember that in mathematics and even physics there are defined/calculated objects (finite groups, positrons) which one knows exist, though it sometimes takes years to find examples of them.
40 I.e. makes uses of them or applies them in accordance with everyday needs or perhaps in agreement with arguments to show the necessity of the application of some scientific tools as the means to gain results that are desirable by standards of daily life. Now all that is a tricky matter and only makes sense with hindsight from this point in time.
41 According to Dummett, this leads to essential consequences for the philosophy of language in general ([3.37], 209–22), although in the *GGA* it is only used in a generalized form. (Ibid., ch 17, 'The Context Principle in *Grundgesetze*'.)
42 'The context principle in fact also governs terms for actual objects, since a grasp of a proper name involves an understanding of its use in sentences' (Ibid., 207).
43 Stekeler-Weithofer ([3.56]) thinks that Frege did not give, up the context principle in the *GGA,* while Kutschera ([3.46]) believes that it does not play any further role in the *GGA,* cf. also [3.37].
44 In Frege's paper *Der Gedanke* [3.16], which is concerned with logical investigations. This paper has been taken up in modern 'philosophy of mind'.
45 One may wonder of course whether 'numbers' are anything we encounter in an ordinary life that is not guided by our cultural upbringing with its set of instituted knowledge.
46 Remember that the classical approach to logic was the partition into: concept, judgement, inference (in syllogistics: deduction, induction, etc.).
47 The expression 'coming about' needs some consideration: its meaning is ambiguous, i.e. it can be understood as literally descriptive, i.e. as the presentation of a set of rules about how to achieve a result (like an algorithm in a computer program) but also as theoretico-explanatory. In the latter case several ways to turn the theoretical understanding into advice for action (making it an action-guiding device) are compatible with the theory.

48 Cf. [3.35]. This means that, as in the case with Plato, a mathematical method in a more general sense has been made fruitful for philosophy.
49 This presentation of the problem situation is of course not 'true to the historical facts'. Frege was interested in anti-psychologism (from our point of view) and as we see from his thesis in analytical sources of knowledge.
50 Except one has the opinion that human beings cannot make mistakes and therefore reflective corrections are inessential and only disturb the peace of the ordinary mind on the positivistic pillow.—'Everything is what it is' as Bishop Buttler is reported to have said—and so we need not care to think about the world.
51 Cf. [3.3], vi-vii, introduction.

> Wenn es eine Aufgabe der Philosophie ist, die Herrschaft des Wortes über den menschlichen Geist zu brechen, indem sie die *Täuschungen* aufdeckt, die durch den Sprachgebrauch über die Beziehungender Begriffe oft fast unvermeidlich entstehen, indem sie den Gedanken von demjenigen befreit, womit ihn allein die Beschaffenheit des sprachlichen Ausdrucksmittels behafter, so wird meine Begriffschrift, für diese Zwecke weiter ausgebildet, den Philosophen ein brauchbares Werkzeug werden können.

Freillich gibt auch sie [die *BS*], wie es bei einem *äußeren* Darstellungsmittel wohl nicht anders möglich ist, den Gedanken nicht rein wieder…

> If it is one of the tasks of philosophy to break the domination of the word over the human spirit by laying bare the misconception that through the use of language often almost unavoidably arise concerning the relations between concepts and by freeing thought from that which only the means of expression of ordinary language, constituted as they are, saddle it, then my ideography, further developed for these purposes, can become a useful tool for the philosopher. To be sure, it too will fail to reproduce ideas in a pure form, and this is probably inevitable when ideas are represented by concrete means.
>
> ([3–57], 7)

52 Cf. [3.59], 43 'The meaning of a word is its use within the language.'
53 Or some sort of topological generalization of it, e.g. Klein's bottle: a closed, one-sided surface that penetrates itself.

BIBLIOGRAPHY

Selected Bibliography of Frege's Writings

3.1 *Über eine geometrische Darstellung der imaginären Gebilde in der Ebene* (On a Geometrical Representation of Imaginary Forms in the Plane). Inaugural dissertation of the Faculty of Philosophy at the University of Göttingen, submitted as a doctoral thesis by G.Frege of Wismar, Jena, 1873 (75pp. + appendix of diagrams).

3.2 *Rechnungsmethoden, die sick auf eine Erweiterung des Größenbegriffs gründen* (Methods of Calculation based on an Extension of the Concept of Magnitude). Dissertation presented by Dr Gottlob Frege for full membership of the Faculty of Philosophy at the University of Jena. Jena 1874 (26pp. + curriculum vitae).

3.3 *Begriffsschrift, eine der arithmetischen nachgebildete Formelprache des reinen Denkens* (Concept-Script: A Formula Language of Pure Thought modelled on Arithmetical Language). L.Ebert, Halle, 1879 (88pp.).

3.4 *Über die wissenschaftliche Berechtigung der Begriffsschrift* (On the Scientific Justification of Concept-Script). In *Zeitschrift für Philosophie und Philosophische Kritik* (Journal of Philosophy and Philosophical Criticism) LXXXI (1882):48–56 (repr. in BS/ Darmstadt).

3.5 *Über den Zweck der Begriffsschrift* (On the Purpose of Concept-Script). In *Jenaische Zeitschrift für Naturwissenschaft (Jena Journal of Science)* XVI (1883), (suppl.): 1–10. Lecture delivered at the meeting of the Jena Society for Medicine and Science, 27 January 1882

3.6 *Die Grundlagen der Arithmetik* (The Foundations of Arithmetic). A Logico-mathematical Enquiry into the Concept of Number, W.Loebner, Breslau, 1884 (119pp.). New impression: M. and H.Marcus, Breslau, 1934. Facsimile reprint of the new impression: Wissenschaftliche Buchgesellschaft (Scientific Book Society), Darmstadt, 1961, and G.Olms, Hildesheim, 1961 (119pp.).

3.7 *Über formale Theorien der Arithmetik* (On Formal theories of Arithmetic). In: *Jenaische Zeitschrift für Naturwissenschaft* (Jena Journal of Science) XIX (1886), (suppl.):94–104. Lecture delivered at the meeting of the Jena Society for Medicine and Science, 17 July 1885.

3.8 *Funktion und Begriff* (Function and Concept). Lecture delivered at the meeting of the Jena Society for Medicine and Science, 9 January 1891. H.Pohle, Jena, 1891 (31pp.).

3.9 *Über Sinn und Bedeutung* (On Sense and Reference). In *Zeitschrift für Philosophie und Philosophische Kritik* (Journal of Philosophy and Philosophical Criticism) C (1892):25–50.

3.10 *Über Begriff und Gegenstand* (On Concept and Object). In *Vierteljahresschrift für wissenschaftliche Philosophie* (Scientific Philosophy Quarterly) XVI (1892):192–205.

3.11 *Grundgesetze der Arithmetik* (The Basic Laws of Arithmetic: Following the Principles of the Concept-Script. Vol. 1). H.Pohle, Jena, 1893 (253pp. with revisions). Facsimile reprint: Wissenschaftliche

Buchgesellschaft (Scientific Book Society), Darmstadt, 1962, and G.Olms, Hildesheim, 1962.

3.12 *Über die Begriffsschrift des Herrn Peano und meine eigene* (On Peano's Concept-Script and My Own). In *Berichte über die Verhandlungen der Königlichen Sächsischen Gesellschaft der Wissenschaften zu Leipzig, Mathematisch-Physikalishe Classe* (Reports on the Proceedings of the Royal Saxon Society for Science in Leipzig, Mathematics/Physics Division) XLVII (1897):361–78. Lecture delivered at the extraordinary meeting of the Society held on 6 July 1896.

3.13 *Über die Zahlen des Herrn H.Schubert* (On H.Schubert's Numbers), H. Pohle, Jena, 1899 (32pp.).

3.14 *Grundgesetze der Aritbmetik* (The Basic Laws of Arithmetic: Following the Principles of the Concept-Script, vol. 2), H.Pohle, Jena, 1903 (265pp. with revisions and glossary of terms). Facsimile reprint: Wissenschaftliche Buchgesellschaft (Scientific Book Society), Darmstadt, 1962, and G.Olms, Hildesheim, 1962

3.15 *Was ist eine Funktion?* (What is a Function?). Festschrift dedicated to Ludwig Boltzmann on the Occasion of his Sixtieth Birthday, 20 February 1904.J. A.Barth, Leipzig, 1904, pp.656–66.

3.16 *Der Gedanke* (The Thought). A Logical Enquiry. In *Beiträge zur Philosophie des deutschen Idealismus* (Contributions to German Idealistic Philosophy) 1 (1918):58–77.

3.17 *Die Verneinung* (Negation). A Logical Enquiry. In: *Beiträge zur Philosophie des deutschen Idealismus* (Contributions to German Idealistic Philosophy) 1 (1918):143–57.

3.18 *Logische Untersuchungen* (Logical Investigations). Part 3: Sequence of Thought. In *Beiträge zur Philosophie des deutschen Idealismus* (Contributions to German Idealistic Philosophy) III (1923):36–51.

3.19 *Gottlob Frege: Nachgelassene Schriften und wissenschaftlicher Briefwechsel* (Gottlob Frege: Posthumous Writings and Correspondence), Hans Hermes, Friedrich Kambartel and Friedrich Kaulbach Posthumous (eds), Hamburg, 1969. Vol. 1: Writings (1969); Vol. 2: Correspondence (1976).

CHAPTER 4

Wittgenstein's Tractatus

James Bogen

I INTRODUCTION

Containing material (mainly on logic and language) dating back at least to 1913 when Wittgenstein was twenty-four, the *Tractatus* was first published in 1921. In 1922 a somewhat revised version was published with a translation by C.K.Ogden and an introduction by Bertrand Russell. The last significant correction to the German text was made in 1933. The second major English translation (by Pears and McGuinness) was published in 1960.[1] It is a short, oracular book. Much of it is aphoristic; some of it, formidably technical. Few of its claims are explained or argued in any detail. Its core is a theory of language which Wittgenstein applies to topics as diverse as ethics, religion, the foundations of logic and the philosophy of science.

The major components of the *Tractatus* theory of language are: (T1) a theory of meaning and truth for elementary propositions *(Elementarsätze)* (*T*4.03, 4.0311; 4.2I–4.24).[2]

(T2) a *construction thesis,* which holds roughly that because all meaningful statements are truth functions of elementary propositions, if we were given all of the elementary propositions, there is no proposition *(Satz)* which could not (in principle at least) be 'constructed' or 'derived from' them (*T*4.26–5.01; 5.234–5.45; 5.5–5.502; 6–6.01); and (T3) a development of the idea that propositions can express every possible fact.

All of this applies only to language as used to say what is true or false. The *Tractatus* does not deal with questions or commands, jokes, riddles, etc—a limitation emphasized in the early sections of *Philosophical Investigations* [4.47].

All three of these involve problematic notions which Wittgenstein criticized harshly in his later work. For example, elementary propositions are supposed to be composed of names which refer to objects, but the

Tractatus supplies no examples of names, and its characterization of objects is fraught with difficulties (see Section XI below). There are neither examples nor clear characterizations of the propositions of T1 and constructions of T2. Indeed, the very notion of a Tractarian proposition is problematical (see Section IX below). To get started, I will use a simple, idealized model which departs from the *Tractatus* as needed to postpone consideration of the difficulties.

II ELEMENTARY PROPOSITIONS

The model features language which describes 'states of affairs'. Tractarian states of affairs *(Sachverhalte)* are possible concatenations of simple elements. A state of affairs obtains *(besteht)* if the relevant objects are concatenated in the right way; otherwise, it does not obtain (2–2.01). For now pretend that states of affairs are arrangements of two-dimensional objects with the following shapes.

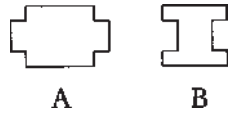

Figure 4.1

Any B-shaped object can connect at either end to any A. Objects of the same shape cannot connect to each other. No object can curve around to connect to itself or to both ends of another object.

Names are signs which refer to objects. Elementary propositions are strings of names (cp. *T*4.21, 4.22, 4.221). Figure 4.2 assigns names ('a_1', 'b_1', etc.) to objects and illustrates three states of affairs (possible concatenations).

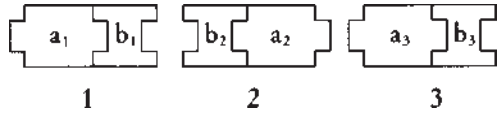

Figure 4.2

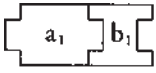
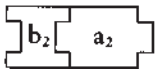
The syntax of a Tractarian language allows as elementary propositions all but only arrangements of names which are isomorphic to possible concatenations of the objects they refer to. In our model the isomorphism is spatial: for example, what we get by writing 'a_1' to the left of 'b_1' is an elementary proposition because object a_1 can be connected to the left side of object b1.'a_1a_2', and 'a_1a_1' and '$b_1a_2b_1$' are not elementary propositions.

Neither is a single name; the model does not talk about objects apart from concatenations. Thus, the syntax of elementary propositions mirrors the geometry of the states of affairs.

Each elementary proposition pictures the isomorphic concatenation of the objects it mentions. Thus 'a_1b_1' pictures



and 'b_2a_2' pictures



(cp. *T*2.13–2.14, 2.15, 2.201, 4.01)

An elementary proposition is true just in case the objects it mentions are concatenated as it pictures them; otherwise it is false (cp. $T_{2.21}$, 4.022, 4.25). An elementary proposition has a sense just in case it portrays a state of affairs (i.e. a concatenation which can obtain). Thus, the relation between the geometries of elementary propositions and states of affairs established by the syntax of our model guarantees a state of affairs (hence a sense) for every elementary proposition and an elementary proposition for every state of affairs. This corresponds to the Tractarian doctrine that elementary propositions cannot portray anything which is impossible, and can portray all possible concatenations of objects because the constraints which determine how symbols can be combined into elementary propositions are identical to the constraints which determine how objects can combine with one another (*T*2.151, less 2.17–2.182).

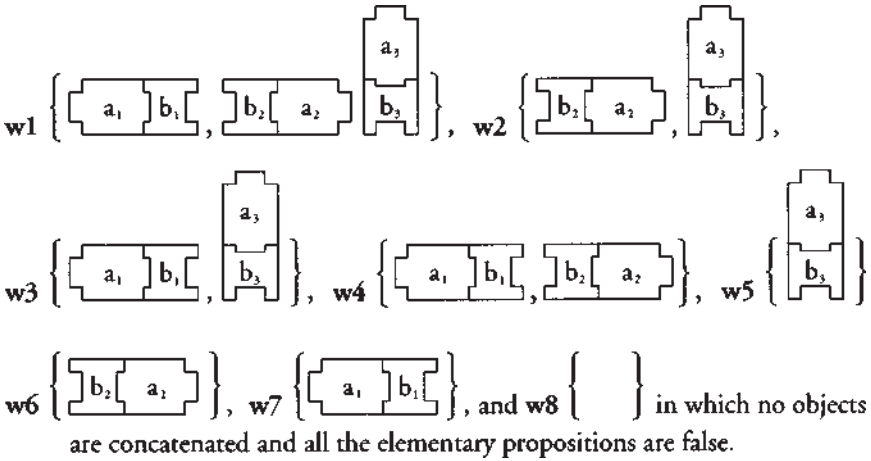
I emphasize that this model is non-Tractarian. Its names and propositions are *marks* (signs) while Tractarian names and propositions are not (see Sections IV and IX below). Two dimensional spatial objects are not Tractarian simple objects (see Section XI below). Bearing this in mind the foregoing illustrates T1—including some crucial features of the *Tractatus* picture theory of language (see Section VIII below)—for elementary propositions.

III T_3 AND THE CONSTRUCTION THESIS

The *Tractatus* says reality is the totality of all 'positive' and 'negative facts'. Positive facts are obtainings of states of affairs and negative facts are their non-obtainings (*T*2.06B). For example if a_1 is connected to the left of b_1, it is a positive fact that a_1b_1. If they are not concatenated it is a negative fact that they are not.[3] Possible worlds are collections of possible facts. The positive facts a world includes, and its including no others, determine which negative facts belong to it (*T*1–1.13; 2.04–2.06).[4]

To illustrate T_2 and T_3, let p be 'a_1b_1', the elementary proposition which pictures the obtaining of state of affairs 1 in Figure 4.2. Let q be 'b_2a_2'. Let r picture the obtaining of 3 in Figure 4.2. If a_1, a_2, a_3, b_1, b_2 and b_3 are the only

objects, and 1, 2 and 3 are their only possible concatenations, the possible worlds are:



According to T_3 and the construction thesis, every positive and negative fact in every possible world can be pictured by propositions included in or constructed from a complete list of elementary propositions. To show how this could be, the *Tractatus* employs the truth table, a gadget which is known and loved by every beginner logic student.[5] In a truth table 'T' indicates truth, and 'F', falsity. Each elementary proposition can be true or false independently of the others. The first three columns of Figure 4.3 represent the possible combinations of truth values for p, q and r. (The ordering of the permutations is idiosyncratic to Wittgenstein. (*T*4.31 ff). Thus in line 1, columns 1, 2, 3, represent the possibility that all of our elementary propositions are true. In line 2, columns 1, 2, 3, p is false while q and r are true. Etc. Each subsequent column represents the truth conditions of non-elementary propositions. Thus ¬ p is true whenever p is false, and false whenever p is true, regardless of the truth values of q and r, p&q is true whenever both p and q are true, regardless of whether r is true, etc.

	p	q	r	¬p	¬q	¬r	pvq	pv¬q	p&q	p⊃q	(pvq)⊃(p&q)	Taut.	Contr.
1	T	T	T	F	F	F	T	T	T	T	T	T	F
2	F	T	T	T	F	F	T	F	F	T	F	T	F
3	T	F	T	F	T	F	T	T	F	F	F	T	F
4	T	T	F	F	F	T	T	T	T	T	T	T	F
5	F	F	T	T	T	F	F	T	F	T	T	T	F
6	F	T	F	T	F	T	T	F	F	T	F	T	F
7	T	F	F	F	T	T	T	T	F	F	F	T	F
8	F	F	F	T	T	T	F	T	F	T	T	T	F

Figure 4.3

Each row corresponds to a different possible world. If p is 'a_1 b_1', q is 'b_2a_2' and r is 'a_3b_3' row 1, represents w 1 in which p, q and r are all true, row 2 corresponds to W2, etc. For each different proposition there is a column which specifies its truth value in each world. Thus, by column 10, **p⊃q** is true in w1, w2, w4, w5, w6, w8, and false in w3 and w7. A proposition is contingent if it is true in at least one world and false in at least one other. Necessarily true propositions ('tautologies') are true in every world. Necessarily false propositions ('contradictions') are false in all worlds (*T*4.46). Because objects are extra-linguistic entities whose natures determine which states of affairs (and therefore which possible facts) there are, the *Tractates* does not think that all necessity and impossibility is propositional (*T*2.014, 2.0141; cp. section XI). But tautology, contingency and contradiction exhaust its propositional modalities.

If (as in our model) there were only a limited number of truth possibilities for elementary propositions, we could prove the construction thesis by simply writing a truth table with a column for every possible proposition. Wittgenstein offered no such proof, presumably because he thought he could not list all of the elementary propositions, and could not rule out the possibility that there are infinitely many of them (*T*4.2211, 5.571). Instead, he suggested that every proposition (elementary as well as non-elementary) can be expressed by one or more applications of an operation he called joint negation and symbolized 'N ' **(ξ)**. ξ is a variable whose values are collections of propositions. The bar indicates that the order of the propositions is indifferent. The joint negation of any ξ is the conjunction of the denials of every proposition in ξ (*T*5.5–5.51). For example, N(p,q,r)=

(1) ¬p&¬q&¬r,
and N([¬p&¬q&¬r], p, q, r)=

(2) ¬(¬p&¬q&¬r)&(¬p&¬q&¬r), a contradiction (cp. 5.5–5.51) ξ can be a one-member collection. For example, we can jointly negate (2) to obtain a tautology,
(3) ¬[¬(¬P&¬q&¬r)&(¬P&¬q&¬r)].

The first step in the construction of any proposition is the joint denial of all of the elementary propositions (*T*5.2521–5.2523, 6–6.6001). Wittgenstein doesn't say what comes next, but we could proceed as follows. At each successive step replace $\bar{\xi}$ by any proposition or propositions you feel like choosing from the elementary propositions and whatever non-elementary propositions have already been constructed. By common sense we shouldn't replace $\bar{\xi}$ with propositions whose joint negation will duplicate results already obtained, and we should keep trying different substitutions until we get a proposition for every column.[6] Such policies might enable someone with enough ingenuity to construct all of the truth functions of a finite number of elementary propositions. But since the choices for $\bar{\xi}$ (and therefore the outcomes of joint negation) are not determined after the first step, Wittgenstein's construction procedure is ill-defined.[7]

In addition to this there is the possibility that there are infinitely many elementary propositions.[8] Wittgenstein mentioned this later as an insurmountable problem for his account of universal and existential quantification. [4.24], 279 The *Tractatus* treats universally quantified propositions of the form $\forall x(Fx)$ as if they were conjunctions expressing agreement with every value of Fx and existentially quantified propositions as if they were disjunctions which are true just in case at least one value of Fx is true. Since the values of the function are propositions, they must themselves be elementary propositions or their truth functions. Suppose the truth conditions of each value of Fx involved a different elementary proposition. If there were infinitely many of them, Wittgenstein argued, they could not be enumerated, and Wittgenstein thought this would rule out constructing universally and existentially quantified propositions by treating them as conjunctions and disjunctions.[9] Indeed, if there were infinitely many elementary propositions, the first step in the construction of any proposition whatever—unquantified or quantified—would have to begin with the joint denial of a group of propositions whose members could not be enumerated. Wittgenstein apparently decided the *Tractatus* could not be adjusted to allow for this. Why didn't he consider construction methods which would not require enumerating all of the elementary propositions? It is plausible that by this time changes in Wittgenstein's ideas about elementary propositions (see section IX below) had not only complicated the problem, but had also led him to doubt whether it was worth pursuing.

If *all* propositions can be constructed (*T*4.51, 4.52, 5) we must be able to construct elementary as well as non-elementary propositions. In effect that would mean detaching each elementary proposition from the set of all elementary propositions. How can repeated applications of joint negation accomplish this? If p, q and r were the only elementary propositions we could construct a proposition with exactly the same truth conditions as p as follows.[10] Having obtained (1) by jointly negating p, q and r, select (1) together with all of the elementary propositions to form the collection [(¬p&¬q&¬r), p, q, r)]. Its joint negation is the contradiction (2) obtained above. Now the joint negation of (2) and p is the conjunction of ¬p and a tautology:

(4) 3&¬p. Finally, N(4)=
(5) ¬(3&¬p). This expression is true just in case (3) is false or ¬¬p is true. Since ¬3 is false in all worlds, (5) is true exactly when ¬¬p is true. Thus (5) has exactly the same truth conditions as p (column 1, Figure 4.3). But this is not the only way to express the truth conditions of p. For example, after the mandatory joint denial of the elementary propositions we can substitute p for $\bar{\xi}$.[11] N(p)=¬ p and N (¬p)=
(6) ¬¬p

which has the same truth values as p.

IV 'A PROPOSITION IS A QUEER THING!'[12]

But in constructing (5) and (6) did we reall y construct p, or just different propositions with the same truth conditions? I he same truth conditions. Furthermore, if propositions are sentences, then, contrary to Wittgenstein, the order of the propositions in $\bar{\xi}$ is not indifferent; N(p, q, r)=¬p&¬q&¬r, and N(r, q, p)=¬r&¬q&¬p have the same truth conditions but '¬p&¬q&¬r' and '¬r&¬q&¬p' are different sentences. Apparently, then, propositions are not sentences. Wittgenstein says that what is 'essential' to a proposition is not the shapes of its signs but rather, the features 'without which the proposition could not express its sense' (*T*3.34B) and which are common to 'all propositions which can express the same sense' (*T*3.341A). Because the sense of a proposition is its truth conditions (*T*2.221, 4.022–4.03, 4.1) propositions with the same truth conditions must have the same essential features. If propositions whose essential features are identical, are themselves identical, Wittgenstein need not worry: p would differ no more from pv2 than Thelonius wearing a hat would differ from Thelonius bare-headed (cp. *T*5.513A, 5.141). Thus, differences between sentences used to express the same

truth conditions need not constitute an objection to the construction thesis.

But if different sentences (marks and sounds) can be counted as one and the same proposition, what *is* a proposition? One thing Wittgenstein says a proposition is is a written or spoken sign in use ('in its projective relation to the world') to picture the world as including a particular situation *(Sachlage)* (*T*3.11, 3.12). A situation is a congeries of obtainings and non-obtainings of states of affairs (*T*2.11). But if different sentences are used to picture the world as including the same situations, they have the same truth conditions and therefore, they must have the same essential features. How can exactly the same essential features belong to all the different sentences which can be used to say the same thing? For example, since a proposition must contain 'exactly as many distinguishable parts as…the situation which it presents' (*T*4.032A) sentences presenting the same situation must somehow have the same number of distinguishable parts. This applies to the 'propositions of our everyday language' for Wittgenstein considered them to be 'in perfect logical order just as they stand' (*T*5.5563A) even though their outward form completely disguises their logical form (*T*4.002CD). Thus, all artificial and natural language sentences which can say the same thing must have the same number of distinguishable parts when they are so used. The question of what these parts are and how to count them exemplifies the difficulty of understanding what propositions are and what they have to do with sentences.[13]

Wittgenstein says other things about propositions which seem to promise help with the counting problem. First, at *T*3.31 propositions and their parts are said to be 'symbols' or 'expressions'. And the symbol (expression) is said to be everything 'essential to their sense' which propositions expressing the same sense 'can have in common'. Thus, where sentences of different lengths are used to express the same sense, the number of words in a sentence need not equal the number of symbols in the relevant proposition. Second, Wittgenstein says pictures, propositions and sentences are not just words or symbols, but facts—the facts that their elements stand to one another in certain relations (*T*2.141, 2.15, 3.14ff). Thus what pictures or asserts that a stands in some relation to b is not the complex sign 'aRb', but the fact that 'a' stands in a certain relation to 'b' (*T*3.1432). The sign 'R' is not treated as a part of the fact (that 'a' and 'b' stand to one another in a certain relation) which says that aRb. This promises some help with the counting problem, for if the symbol is a fact, the number of elements it contains need not be the same as the number of words used make the assertion. But how are the parts of such facts to be counted, and why is not their number directly determined by the number of

signs they involve? The third characterization of the proposition suggested in the *Tractatus* is relevant to this.

As a group of names arranged to depict the world as including a concatenation of the objects to which they refer (*T*4.0311) the elementary proposition resembles what is supposed to have suggested the picture theory to Wittgenstein—a model[14] composed of toy cars, pedestrians, etc, representing real automobiles, people, etc., and used to allege that an accident had occurred in a certain way.[15] But it is an important fact about such representations that one and the same picture or model can be used to claim that this is how an accident occurred, or that this is how it *did not* occur. (It can also be exhibited as a representational sculpture which makes no claim at all.) Strictly speaking, truth conditions belong to assertions ordinary pictures can be used to make. By itself, apart from any such use, the picture has no truth conditions. By the same token if propositions represented facts in the same way the model represented the accident, they would have no truth conditions. The reason the proposition has a sense is that, in addition to picturing, it asserts that the world is as pictured (*T*4.022, 4.023E, 4.06). If the proposition is an assertion which can be made with more than one sentence instead of a sentence used to assert, the number of its parts would depend upon the number of things done with signs instead of depending on the number of signs used. For example, the countable parts of the an elementary proposition would be references to objects. At *T*3.3411 'the real name of an object is what all symbols which designate it have in common'. The suggestion is that what they have in common is their use to refer. Indeed this promises a way to disregard as inessential not just the number of signs in sentences used to say the same thing, but *any* features possessed by some of those sentences but not others.[16]

How do the different things the *Tractatus* says about propositions hang together? The later Wittgenstein thought they do not. In the *Philosophical Investigations* [4.47], he spoke of the tendency to think of the proposition as 'a pure intermediary between the prepositional *signs* and the facts. Or even to try to purify, to sublime, the signs themselves'.[17]

It is plausible that the Tractarian symbol exemplifies the first tendency. It is plausible that the conception of a proposition as a sign or a fact involving signs whose essential features are determined by what it is used to say exemplifies the second. It is plausible that the picture theory of language exemplifies both.

V FALSE ASSERTIONS

The *Tractatus* attempts to solve a puzzle about falsehood dating back to Plato's Theaetetus:

> [If]…a man who is judging some one thing is judging something which is…that means that a man who is judging something which is not is judging nothing…But a man who is judging nothing is not judging at all…And so it is not possible to judge what is not, either about the things which are or just by itself.[18]

To get the problem of false assertion Wittgenstein addressed, replace Plato's talk of judgement and what is judged with talk about assertion and what people assert. To say that some specific state of affairs or situation ('some one thing') belongs to the actual world a proposition must tell us *which* state of affairs or situation its truth value depends on. Otherwise, for example, state of affairs ab would have no more bearing on the truth or falsehood of the proposition 'ab' than any other concatenation of a and b or the concatenation of other objects. But a proposition is false only if what it claims to be the case is not one of the positive or negative facts which make up the actual world. The problem of false assertion is the problem of explaining how a proposition can specify the putative fact it claims is the case (as it must do to have a sense) if it is false and there is no such fact. For example, how can a proposition say that ab obtains when it is false and the actual world does not include that concatenation? And if ab obtains, how can '¬ab' specify the negative fact required for its truth?

The picture theory solves the problem by rejecting the assumption (which generates it) that a proposition cannot specify which fact its truth requires unless that fact is actually there to be specified. Elementary propositions are pictures whose elements are names of simple objects (*T*3.203). 'One name stands for one thing, another for another thing, and they are combined with one another. In this way the whole group—like a *tableaux vivant*—presents a state of affairs' (*T*4.0311). Instead of naming (standing in a referring relation) to a putative fact, a proposition specifies what its truth requires by 'picturing' it, where picturing does not require the actual existence of the putative fact. In order for an elementary proposition to say that ab, the names 'a' and 'b' must refer to objects a and b, respectively, and those objects must be *able* to be arranged as the proposition shows them to be. But this does not require the state of affairs (ab) to actually obtain. And because the possibility of its obtaining consists of nothing more than the possession by a and b of the abilities required for concatenation, the state of affairs (the possible fact that ab obtains) is not an entity the proposition must refer to in order to claim that ab is the case.

Thus the proposition 'ab' can be false as long as there are objects (capable of concatenating) for its names to refer to, and an actual world which fails to include the obtaining of ab.

Complex situations, including non-obtainings of states of affairs, are pictured by non-elementary propositions whose construction—Wittgenstein thought—requires nothing more than the joint negation of collections of propositions. Whatever difficulties this may involve, there is no reason to think, e.g., that the construction of '¬ab' should require ab to obtain any more than would the assertion 'ab'. Thus, Wittgenstein can say that 'a proposition which speaks of a complex' is false rather than 'meaningless *(unsinnig)* if the complex does not exist' as it would be if complexes had to be named in order to be mentioned (*T*3.24B). With regard to the problem at hand, the non-existing complexes are the putative facts mentioned by false propositions.

The notion of picturing involved in this solution is a primitive. Instead of trying to define it Wittgenstein designed his account of elementary propositions and their truth functions to secure that, as long as there are objects for names to refer to and an actual world for the proposition to represent, the proposition can picture the world as including a putative fact regardless of whether it belongs to the actual world. In order to appreciate the elegance of this solution to the problem of false assertions and also to introduce some of its difficulties it helps to look at the competition.

VI SOME REJECTED ACCOUNTS OF FALSE JUDGEMENT

Wittgenstein intended his account to avoid problems he found in the solutions of Frege and Russell, and a theory of Meinong's they all rejected. Before he became Wittgenstein's teacher Russell entertained and rejected Meinong's idea that a proposition has meaning by virtue of doing what amounts, ignoring details, to referring to the fact whose existence is required for its truth.[19] Meinong called these 'Objectives'. The Objective signified by a false proposition like 'Napoleon was defeated at Marengo' must enjoy a shadowy grade of existence—robust enough to give meaning to the proposition, but not robust enough to make it true. Russell rejected this because he believed philosophy must be constrained by a 'Vivid sense of reality', and was convinced that 'there is no such thing as [the fact that] Napoleon was defeated at Marengo'.[20] In addition to dispensing with the Objective, his treatment of the *Theaetetus* problem[21] was (like Wittgenstein's) intended to avoid the ontological commitments of the account Frege

devised before the turn of the century.[22] Let us look at Frege's before turning to Russell's.

In Fregean semantics propositions can have meanings of two sorts—sense and reference. All propositions have senses. Frege calls the sense of a proposition a 'thought'—an unfortunate term because his 'thoughts' are structures which are as they are quite independently of anyone's psychological states. Their study belongs not to psychology, but to logic and the philosophy of language. Logical relations (like entailment) are grounded in structural features which Fregean thoughts possess regardless of whether anyone grasps them, and which they would have had even if there had never been any minds. Frege says the existence and structure of a thought depends no more upon anyone's thinking than the existence of a mountain depends upon anyone's travelling over it.[23]

According to Frege not all propositions have truth values.[24] Those that don't have sense but no reference. A proposition is true if its referent is an object Frege calls The True, and false if its referent is The False. Which (if either) a proposition refers to depends upon the thought it expresses together with how things are. For example, the sense of 'Bud played faster than Thelonius' is such that this proposition refers to The True if Bud actually did play faster (he did) and to The False if Thelonius played faster (he did not).[25] Which thought a string of words is used to express depends upon the psychology of those who use it. But once this is established its truth conditions, i.e. what is required for it to name The True (and what is required for it to name The False), depend entirely upon the structure of the thought. The judgement (assertion) that a proposition is true commits one to its naming The True. If it does, the judgement (assertion) is true; if not it is false. But whether or not the proposition is true does not depend upon whether it is judged or asserted.

This solution is Platonistic. But because it does not posit different grades of existence it is not Meinongian. Consider the false proposition 'Thelonius played faster than Bud'. Its referent (The False) and its sense enjoy exactly the same kind of existence as Thelonius Monk, Bud Powell and the proposition itself.[26] Thus, the price Frege pays to avoid Meinong's two grades of existence is Platonism required to posit Fregean thoughts, The True, and The False.

Wittgenstein rejected the Platonism of Frege's account, and along with it, the Fregean idea that propositions are names, let alone names of The True and The False (*T*3.143, 4.063, 4.431, 4.442).[27] He tells us not to say propositions have senses—as if a sense were a Fregean thought which could exist even if no proposition had it, and as if having a sense involved a two-term 'having' relation between a proposition and its sense. Instead of saying a proposition has a sense we can simply say it pictures the world

as including the situation it presents (*T*4.031B). For a proposition to be true is not for it to name The True but rather, to picture the world as containing a situation it actually contains. Russell's alternative to Frege and Meinong was to maintain that truth and falsity belong primarily to complex structures assembled by a person in the course of believing, disbelieving, doubting, understanding, questioning, or any of the other mental states which Russell later called 'attitudes to ideas' and which are now called 'prepositional attitudes'.[28] In what follows I will use the term 'judgement' generically for all of these attitudes. A Russellian judgement is not a mind's attitude toward a pre-existing, pre-structured Fregean thought. Russell eschewed these as well as Meinongian Objectives. Instead, he treats judgement as consisting of a many-termed relation between the judging mind and a number of (what he considered less exotic) items. In judging that one of these items, a, stands in some relation, R, to another item, b, one puts together what Russell calls a proposition. Unlike Fregean propositions whose constituents were words, and Wittgensteinian propositions composed of symbols, a Russellian proposition is composed in this case of the objects a and b themselves, the relation, R, and a gadget which orders them into a proposition and thereby determines its structure.[29] These constituents exist on their own whether or not anyone makes a judgement about them.[30] If they actually are as judged (e.g. if someone believes that a is louder than b, and a actually is louder) the proposition is true. But since their collection into a proposition requires nothing more than judgement, false propositions can be put together in exactly the same way as true propositions. This treatment of the problem of false judgement does not commit Russell's ontology to anything beyond the minds which judge, the relation which constitutes judging, and the constituents which judgement puts together to form propositions. Thus, Russell avoided positing the Meinongian Objectives and Fregean thoughts which offended his ontological sensibilities by plucking out of his account of judgement the notion of prefabricated contents of judgement (Objectives, Fregean thoughts) which do not depend upon judgement for their existence, their logical structures, or their truth conditions. The development of the picture theory was driven by Wittgenstein's dissatisfaction with this no less than with Frege's and Meinong's theories.

In 1913 Wittgenstein argued that Russell's theory was inadequate because it could not rule out the possibility of judging nonsense, i.e. believing, affirming, etc., what lacks truth conditions. The problem was that Russell's account does not constrain the items which can belong to propositions or the ways in which judging can arrange them as needed to rule out such nonsense judgements as 'that this table penholders this book'.[31] This defect is hard to remedy. Even if Russell had a principled way to limit the selection of constituents to items which could belong to a

fact his theory would not know how to prevent someone from judging a disorganized jumble.

Well then, how does Wittgenstein avoid the possibility of nonsense judgements? He says what is needed to avoid Russell's mistake is a correct 'explanation of the form of the proposition, 'A makes the judgement p'…[which shows] that it is impossible to judge a nonsense *(einen Unsinn)*' (5.5422). The mistake, says Wittgenstein, was to analyse 'A believes that p is the case', 'A thinks p', etc.', as claiming that a proposition p stands in some relation 'to an object, A' (T5.541C-D).[32] Properly analysed, 'A judges p' and the rest turn out to be…of the form '"p" says p' (5.542). In 'A judges p', 'A' appears to be a name which refers to a judging subject. But the only names the Tractarian analysis of a proposition can include refer to Tractarian objects, and Wittgenstein believes that judging subjects are not objects (*T*5.5421). Thus neither 'A' nor anything else which purports to name a judging subject can occur in the analysis of 'A judges p'. More surprisingly Wittgenstein's analysis does not mention judgement either. If '"p" says p' is the proper analysis of 'A judges p' then the situation Russell analysed as including a judging subject, the judging, and a Russellian proposition consisting of objects arranged by the judging reduces to a situation consisting just of a picture, sentence, or proposition, 'p', and its expression of its sense, 'p' says that it is the case that p because its elements are 'correlated with' the elements of the putative fact that p (*T*5.5421). Thus, where Russell purged his ontology of Meinongian Objectives and Fregean senses by reducing the content of a prepositional attitude to a collection of objects assembled by judging, Wittgenstein reduced judging (believing, and all other sorts of thinking) to a proposition's (picture's, or sentence's) expression of a sense.[33] Instead of analysing someone's judgement that ab as a relation between a judging subject (mind, soul, etc.) and objects a and b, Wittgenstein analyses the judgement as consisting essentially of a Tractarian picture (proposition or sentence) which depicts a and b as concatenated.[34] This reduction of judgement to the expression of a sense transforms the problem of explaining why there can be no nonsense judgements into the problem of explaining why propositions cannot assert nonsense on the order of 'the table penholders the book'.[35] Because Tractarian names can only combine to form elementary propositions which picture possible concatenations of their referents (*T*2.16–2.17, 2.18–2.203)[36] elementary propositions cannot lack senses. Since all non-elementary propositions are truth functions of elementary propositions, no proposition can be nonsensical. If judgement can be analysed as the *Tractatus* proposes, this rules out the possibility of nonsense judgements.

VII UNASSERTED PROPOSITIONS

The question of how there can be false propositions has a counterpart in the question of how there can be judgements about and logical relations between propositions which are not themselves judged. How can I believe that (p) Theophrastus wrote the book we know as Aristotle's *Politics* only if (q) Theophrastus held inexcusably stupid political views, even though I disbelieve p and have no opinion about q? How can it be the case that every conjunction entails its conjuncts regardless of whether anyone ever has or will ever even grasp the sense of a given conjunction, its conjuncts or the claim that the one entails the others?

Frege's theory allows for all of this by treating the sense of a proposition as a structure whose composition does not require judgement. Thus I do not have to believe that Theophrastus wrote the *Politics* in order for the sense of p to be such that p is true only if he did. The same holds for q. I happen to believe the hypothetical but my doing so is not what gives it the truth conditions it has. And if logical relations depend upon senses whose existence and structure are quite independent of judgement, no judgement is required for the entailment of p by p&q.[37]

Hypotheticals and entailments raise problems for non-Fregean accounts which provide no contents to judge apart from someone's judging them. One such account is Kant's theory that the antecedents and consequents of hypothetical judgement are themselves judgements, rather than pre-existing contents.[38] Because the contents of Russell's judgements are creatures of the judging mind, it is astonishing to find the multiple-relation theory of judgement in *Principia Mathematica* whose very programme assumes that logical relations are not psychological and that their explanation requires no reference to the judging mind.[39]

By reducing judgements to the expressions by propositions of their senses, the *Tractatus* turns our questions about hypotheticals and logical connections into questions about unasserted propositions. For example, the question of how I can believe a conditional without believing its antecedent and its consequent becomes a question about how a conditional proposition can fail to assert its antecedent and its consequent. Since Wittgenstein holds that '… propositions occur in other propositions only as bases of truth operations' (*T*5.54)—i.e. as members of jointly denied collections of propositions (*T*5.21)—he need not worry, e.g., about how propositions p and q can occur unasserted in p⊃q; his answer is that they do not. But the construction of any proposition requires the joint negation of the elementary propositions. Therefore just as Kant needs to explain how we can judge that a hypothetical is true without

judging the truth of its component judgements, Wittgenstein must interpret an expression like 'N(p,q,…) as including p and q without including the assertion that it is the case that p (or that q).

Tractarian operations take us from propositions to propositions (*T*5.21–5.23). Even though we can express a negative proposition without using the sign for the proposition it denies, the negative proposition must still be constructed 'indirectly' from the positive proposition (*T*5.5151). Thus, in order to say that state of affairs ab does not obtain, we must use the *proposition* 'ab' (in joint negation, I suppose) not just the sentence (sign) customarily used to say that ab obtains. But elementary propositions do not just show states of affairs; they also say that they obtain (*T*4.022, 4.023E, 4.06). The *Tractatus* does not address the question of how to use the proposition 'ab' to construct '¬ab' without asserting what we wanted to deny—that ab is the case.

Since we can write down a sentence without asserting anything, things would be easier if Wittgenstein had treated joint denial as taking us from sentences to sentences instead of propositions to propositions. But he does not, and it is not clear how he could have. The joint denial of p and q has no definite truth conditions unless p and q each have definite truth conditions (*T*5.2314). For Frege, propositions were sentences which could have truth conditions without benefit of assertion just by virtue of their assignment to Fregean thoughts. But Wittgenstein rejected Frege's account of the senses of propositions and treated sentences as having senses only as used to assert.[40] It seems to follow that if the 'p' and the 'q' in 'N(p, q)' are sentences, then 'N(p, q)' has no definite truth conditions unless 'p' and 'q' are used to assert something. It would be nice if a sentence could have the obtaining of ab as its truth condition just in virtue of its employment in the construction of the proposition which says that ab does not obtain. But the *Tractatus* does not set out a mechanism for this.

In the 1913 theory of knowledge manuscript which Wittgenstein criticized, Russell himself said the 'chief demerit' of his theory of judgement was that it could not explain logical relations among unjudged propositions.[41] But Wittgenstein's objections centred on the problem of nonsense judgements. I find no record of objections based on the question of logical relations between unjudged propositions. This is surprising, for Wittgenstein certainly knew the relevant parts of Frege's work. No less surprisingly, the *Tractatus* does not indicate how to avoid the analogous problem of how logical relations can obtain between unasserted propositions.

VIII LOGIC, PROBABILITY, AND THE CONSTRUCTION THESIS

In spite of this difficulty, the construction thesis provided an interesting and influential treatment of logical and probabilistic relations between propositions. By the construction thesis, the truth value of every proposition is determined by the truth values of elementary propositions, and elementary propositions are truth functions of themselves (*T*5). Wittgenstein calls each combination of truth values of elementary propositions sufficient for the truth of a proposition a truth ground of that proposition (*T*5.1241C, 5.01). Thus, for elementary propositions p, q, r_1, r_2,…r_n, the truth grounds of p&q are ⟨true p, true q, true r_1⟩, ⟨true p, true q, false r_1⟩, ⟨true p, true q, true r_2⟩, ⟨true p, true q, false r_2⟩, and so on for every r_i. Since the truth values of the rs are irrelevant to the truth value of the conjunction we can write '⟨true p, true q⟩' as an abbreviation for the full list of its truth grounds. The truth grounds of **p⊃q** are ⟨true q, true p⟩, ⟨true q, false⟩ and ⟨false q and false p⟩. And so on.

Wittgenstein explains deductive inference as resting on nothing more than relations between truth grounds (*T*5.12). For example, since the truth ground of p&q, includes ⟨true p⟩ , p is true in every possible world in which p&q is true. This explains why p&q entails p, and accounts for the validity of the argument: p&q; therefore p. On the other hand, because p is made true by ⟨true p, false q⟩ as well as by (true p, true q), p&q is false in some worlds in which p is true. That is why p does not entail p&q and we cannot infer the latter from the former. ¬p entails **p⊃q** because both its truth grounds (⟨false p, true q) and (false p, false q⟩) are truth grounds of **p⊃q**. One proposition contradicts another just in case their truth grounds exclude one another.

Russell called this, 'an amazing simplification of the theory of inference, as well as a definition of the sort of propositions that belong to logic'. ([4.33], xvi). The simplification consists of the fact that if Wittgenstein is right there is no need for laws of logic as traditionally conceived. Russell's idea that '(p or p) implies p' is analogous to such '…particular enunciations in Euclid' as '…let ABC be an Isosceles triangle; then the angles at the base will be equal' is an example of the traditional view.[42] According to this the inference of the disjunction 'John Carter played the clarinet' from the disjunction 'John Carter played the clarinet or John Carter played the clarinet' is justified by its falling under the law '(pvp)⊢p' in the same way that the claim that the angles at the base of a particular isosceles triangle are equal is justified by its being an instance of the Euclidean principle. Without such maximally general truths (axioms and their consequences) it would be impossible to explain entailment or inference. But if Wittgenstein is right and logical relations are nothing more than relations between truth grounds, what justifies the inference of

one proposition from another is the propositions themselves and '"laws of inference"…supposed to justify inference…[by]…Frege and Russell…[are]…superfluous' (*T*5.132). The connections between truth grounds which constitute logical relationships between propositions can be established and exhibited by constructing them from the elementary propositions. And this would suffice to establish whether one entails or contradicts the other. And given a logically perspicuous notation, propositions could be written down in a form which clearly exhibits relations between their truth grounds (*T*5.1311). Finally, the propositions (like '(pvp)—| p' and *modus ponens*) which Russell called laws of logic turn out on Wittgenstein's view to be nothing more than tautologies (*T*6.1 13ff.) whose truth can therefore be fully explained by construction.

Wittgenstein applies the same strategy to the explanation of probabilistic relations between propositions.

> If T_r is the number of the truth grounds of a proposition 'r', and if T_{rs} is the number of the truth grounds of a proposition 's' that are at the same time truth grounds of 'r', then…the ratio T_{rs}: T_r is the degree of *probability* that the proposition 'r' gives to the proposition 's' (T5.15).

For example, by rows 1, 2, 5 in Figure 4.3, three of the four truth grounds of r are also truth grounds of $(pvq) \supset (p\&q)$, and its probability given r is ¾. By rows 1, 3, (p&q) is probabilistically independent of r: (p&q) shares half of the truth grounds of r. The fact that the probability of q given p is 1 if p entails q, and 0 if p contradicts q is similarly explained, as is the fact that conditional on any consistent proposition, the probability of a tautology is 1 and the probability of a contradiction, 0 (cp. *T*5.152 C, D).[43]

Elementary propositions are probabilistically independent because the truth value of each one depends on the obtaining of a different state of affairs. 'States of affairs are independent of one another'; the obtaining or non-obtaining of any given state of affairs has no influence whatever on the obtaining or non-obtaining of any other (*T*2.061, 2.062). If r and s are elementary propositions, their respective truth grounds will be {⟨true r, true s⟩, ⟨true r, false s⟩} and {⟨true s, true r⟩, ⟨true s, false r⟩} (ignoring irrelevant propositions), r and s share just one truth ground so T_{rs}=1. Since r has two truth grounds, T_r=2, and the probability of r conditional on s=T_{rs}/T_r=1/2 (*T*5.252).

This makes all probability conditional and construes conditional probability as a logical relation determined by the truth grounds of the relevant propositions. Since truth grounds are completely determined by meanings, Wittgenstein's account makes probability assignments a priori and analytic. Tractarian probability is objective as well. The probability you assign to a proposition will depend upon what you take

the relevant truth grounds to be. But there is an objective fact of the matter as to what the relevant truth grounds actually are, and that makes real probabilities objective and independent of subjectively influenced assignments.[44]

This sort of approach dates back to Jacques Bournoulli (1713) and Laplace (1812). It was revived by Keynes in 1921. As discussed by the Vienna Circle from 1927 on, and modified by Waisman, Wittgenstein's version gained its influence by attracting Carnap's interest.[45] Its importance turns in part on Wittgenstein's second thoughts about the independence of elementary propositions. By 1929 his thinking about 'the logical analysis of actual phenomena' persuaded him that in order to explain, e.g., why the same colour cannot have different hues or degrees of brightness at the same time, he must suppose that numbers can occur in elementary propositions.[46] This would make some elementary propositions mutually incompatible. But if one elementary proposition can confer a probability of 0 on another, it is natural to ask whether elementary propositions can entail one another,[47] and more to the point, to consider the possibility of conditional probabilities among elementary propositions ranging all the way from 0 to 1. These possibilities became essential to Carnap's thought, and thus to the development of the logical treatment of probability in this century.

Despite a number of attractive features (including its conformity to standard conditions on a probability calculus)[48] the *Tractatus* story has two remarkable drawbacks. First, it is silent about what empirically observed frequencies could have to do with probability estimates. This renders it incapable of application to statistical reasoning from sample populations and to learning from experience. Second, if probabilistic relations between natural language propositions (including those of the sciences) depend upon relations between their truth grounds, the assignment of probabilities to them is impossible unless they can be analyzed to determine which elementary propositions and states of affairs are involved in their truth conditions. As will be seen below, the *Tractatus* discussion of objects and names, states of affairs and elementary propositions does not indicate what such an analysis would involve, how, or even whether it could be accomplished.[49]

XI TRACTARIAN PHILOSOPHY OF SCIENCE

If states of affairs are mutually independent there are no causal connections (deterministic or stochastic) between them (*T*5.135–5.1361, 6.37). If elementary propositions are mutually independent, they cannot influence each other's probabilities any more than they can entail or

logically exclude one another. Thus, the *Tractatus* is no place to be a realist concerning laws of nature.

But although states of affairs are independent of one another, complex situations—patterns of obtainings and non-obtainings of states of affairs—are not. If they were, non-elementary propositions would be as logically and probabilistically irrelevant to one another as elementary propositions. By allowing non-trivial, logical and probabilistic connections between truth functions, Wittgenstein leaves open the possibility, e.g., that universal gravitation might be a law of nature which embodies probabilistic and logical connections between non-elementary propositions and objective dependencies among complex situations.

Instead of denying this possibility, Wittgenstein says the belief that 'the so-called laws of nature' explain natural phenomena is an illusion *(Täuschung)* (*T*6.371). This is because he thinks 'the so called laws of nature' (a mixed lot including 'laws of conservation' (*T*6.33), the 'law of least action' (*T*6.3211), 'the principle of sufficient reason' and 'laws of continuity in nature' (*T*6.34), as well as the laws of Newtonian mechanics (*T*6.341A, 6.342B) and other such theories) are creatures of convention. Here is why.

If states of affairs are mutually independent, scientifically interesting deterministic and stochastic dependencies can hold only between complex situations. But complex situations are collections assembled by linguistic practice from a fixed stock of possibilities for obtainings and non-obtainings of individual states of affairs. In the absence of natural connections between the obtainings and non-obtainings of any states of affairs, the only connection the *Tractatus* allows, e.g., between ab and cd, would be constituted by linguistic conventions. Different natural and artificial languages need not allow for the expression of all or of the same truth functions of elementary propositions. Thus, one language might enable its speakers to say things whose truth values depend on the joint obtaining of ab and cd while another language does not. Wittgenstein thinks of scientific theories as embodying conventions for describing the world. These conventions determine how states of affairs will be collected and thus what complex situations the science will treat. Thus Newtonian 'mechanics determines one form of description of the world by saying that all propositions used in… [its] description must be obtained in a given way from…the axioms of mechanics' (*T*6.341A). Wittgenstein illustrates this by analogy to a procedure for describing a surface covered with an irregular pattern of black spots by laying a square-meshed net over it and saying for each square whether it is black or white. The coarseness of the net will influence the accuracy of the descriptions, but in different ways for differently shaped meshes. But even so we can allow for this by adjusting the degree of coarseness to the

shape of the mesh, and equally accurate descriptions can be obtained through the use of at least some different nets. Thus, even if some meshes would not permit accurate enough descriptions for our purposes, the pattern of spots does not uniquely favour any one net. By analogy the world is nothing more than the obtainings and non-obtainings of situations which do not uniquely favour the descriptive conventions of any particular scientific language. The laws of Newtonian mechanics do not explain the obtainings or non-obtainings of any of the states of affairs of which any world is composed. Instead, they constrain their organization into complex situations by requiring, e.g., that we describe motions in terms of mass, force and acceleration—all of which involve convention-driven groupings of naturally independent states of affairs.

So much for Newtonian laws of motion. Laws like the principle of sufficient reason do not explain anything either; they are higher-level constraints on description (*T*6.35B).[50] We can learn something about the world from the fact that it 'can be described more simply with one system of mechanics than with another' and by 'the precise *way* in which it is possible to describe it' by Newtonian mechanics (*T*6.342B).[51] That is because obtainings and non-obtainings of states of affairs which do not depend upon linguistic conventions constrain the scientist's ability to construct and use theories and the results their use can bring. But all the same 'the possibility of describing the world by means of Newtonian mechanics tells us nothing about the world' (*T*6.342B). The possibility of describing the spotted surface did not require the shapes or spatial arrangements of the spots to resemble the shapes or arrangements of the mesh of the net chosen to describe them. By analogy, if states of affairs are mutually independent and if theory and theory choice are conventional as Wittgenstein thinks they are, the possibility of Newtonian descriptions does not require states of affairs to fit any more naturally into Newtonian groupings than into complex situations resulting from the groupings of any other theory.

The idea that regimenting and organizing descriptions of phenomena is the real function of the explanatory principles of physics is a venerable one held by philosophers who understood and respected the sciences no less than Duhem did. But motivated as it was by Wittgenstein's conventionalism and his views on mysticism (see Section XII below), Tractarian philosophy of science contains the seeds of what became an increasingly unsympathetic attitude towards the natural and behavioural sciences. The 'whole modern conception of the world', said Wittgenstein, 'is founded on the illusion…that the so-called laws of nature' and by extension, the sciences which invoke them 'explain natural phenomena' (*T*6.371–6.372). People who hold this conception treat the laws of nature 'as something inviolable, just as God and Fate

were treated in past ages'. Wittgenstein preferred the 'view of the ancients' for its acknowledgement of the inexplicability of God and Fate over 'the modern system…[which] tries to make it look as if *everything* were explained' (*T*6.372). Time brought no rosiness to Wittgenstein's opinion of 'the modern system'. According to the later works, science is grounded just as much in 'forms of life' and social practices as any other activity involving language use. And it is no better justified by such grounding. This picture, along with Wittgenstein's distaste for the arrogance he attributed to science descends directly from the philosophy of the *Tractatus*.[52]

X TROUBLES WITH OBJECTS

Unlike the two-dimensional objects in my simplification (see Section II above), the objects Tractarian names refer to are 'simple' and 'indivisible' (*T*2.02), unalterable and unchanging, and eternal (*T*2.022, 2.024–2.0271). Sense data, ideas, sensations, direct experiences and other such mental items posited by psychologists and philosophers lack these virtues. According to the theories which appeal to them they are all evanescent, most of them are complex, and some are changeable. This marks a crucial difference between the *Tractatus* and a good deal of the empiricist philosophy commonly associated with it. G.E.Moore, Bertrand Russell, members of the Vienna Circle and others Wittgenstein encountered both before and after the *Tractatus,* held that the analysis of ordinary and scientific language terminates in perceivable objects which belong to the foundations of empirical knowledge. For Russell these were sense data. He believed that only statements whose fully analyzed versions mention sense data can be empirically tested. And he believed we could not understand our own utterances unless they made reference to such objects of direct acquaintance. In contrast to all of this and to Wittgenstein's later work as well, the *Tractatus* is not greatly concerned with epistemology.[53] Tractarian objects belong to an ontological theory about the ultimate composition of the world rather than an epistemological theory about our knowledge of it. Tractarian objects are the ultimate components of the facts we form beliefs about rather than the evidence we use to justify empirical beliefs. And even though they are the ultimate objects of reference according to Tractarian semantics, the *Tractatus* does little or nothing in the way of appealing to objects to explain how languages are actually learned and utterances understood.[54] Wittgenstein's later remark concerning Socrates' dream of analysing complexes into simple components that '[e]xperience certainly does not show us these elements' is quite faithful to the objects

of the *Tractatus,* and was probably meant to apply to them [4.47], 59; [4.25], 202 A-C).

Things were not always so. Wittgenstein's pre-*Tractatus,* notebooks sometimes suggest that 'patches in our visual field' might be the referents of genuine names.[55] Wittgenstein's conversations with Schlick and Waisman, after his return to Vienna clearly suggest an epistemological development of Tractarian ideas. Around 1930 Waismann wrote 'Theses', an epistemologically oriented adaptation of the *Tractatus* which appears to have had Wittgenstein's (temporary) blessing.[56] But the notebooks also consider the possibility of objects as non-Russellian as watches and mass points.[57] The *Tractatus* is remarkable for its lack of any such suggestions. In spite of Wittgenstein's willingness to speculate elsewhere about what objects might be, the *Tractatus* leaves this as an exercise to the student. It is plausible that this is because Wittgenstein had hit upon an approach to semantics which required objects without providing any guide whatever to what they might be.[58] It is also plausible that the *Tractatus* is not driven by interests which required Wittgenstein to continue his pre-Tractarian speculations about what the objects are (see Section XII below).

Because states of affairs are just concatenations of objects, we cannot know what the states of affairs are unless we know what the objects are. But if we do not know what objects there are, we cannot know the meanings of simple names. But then we cannot understand elementary propositions either, for an elementary proposition is an arrangement of names whose sense is a function of their meanings. Furthermore, although the *Tractatus* speaks of knowing 'on purely logical grounds' that there must be elementary propositions (*T*5.5562), it says it is impossible to determine a priori what the elementary propositions are (*T*5.5571) or what their forms might be (i.e. how many different names they can contain, and in what arrangements) (*T*5.5541–5.555). Instead, '…the application of logic decides what elementary propositions there are' (*T*5.557). I suppose this means the only way to discover the elementary propositions would be to try analysing non-elementary propositions (cp. *T*4.221A). You might start with a list of arbitrarily chosen candidates for elementary propositions and try to express the truth conditions, for example, of colour claims, by joint negation, modifying the original list of putative elementary propositions as needed to obtain the required results. If that worked you could repeat the process, adjusting the list as needed to construct other propositions, and so on.

Be that as it may, no such project is undertaken in the *Tractatus,* and the *Tractatus* does not provide the materials for any of the reductions or analyses the construction thesis might lead us to expect (including, e.g.,

the application of its treatment of logic and probability to natural language claims (see Section IX above)).

A survey of the kinds of features Tractarian objects are supposed to have raises questions about whether one object (hence one state of affairs) can be discriminated from another. If they cannot be discriminated, it is hard to be optimistic about the prospects for undertaking the constructions the *Tractatus* neglects. The features of Tractarian objects are of three kinds.

1 Each object has trans-world, 'internal features' constituted by its ability to concatenate with one or more other objects (and its inability to concatenate with still others). Thus, the internal features of objects determine which states of affairs they can belong to (*T*2.0123B). The natures of all of the objects taken together determine what worlds are possible; possible worlds differ from one another just in virtue of the concatenations of objects they contain and fail to contain. Although configurations of objects change from world to world, the internal features of an object remain constant over all possible worlds including even worlds in which no situation to which it can belong obtains.
2 Wittgenstein mentions 'external' properties (*T*2.01231, 2.9233, 4.023). He doesn't say much about what they are, but we can guess. Since an object's internal properties are features it has in all worlds (*T*4.123), its external features should be properties it has in the actual world but lacks in some other worlds. What would these be? Because no elementary proposition is true in every world, no concatenation to which an object can belong obtains in all worlds. Thus the external features of an object should consist of its belonging to whatever concatenations it actually belongs to along with the non-obtaining of other states of affairs to which it can belong. Perhaps there are other sorts of external features, but Wittgenstein does not mention them.[59]
3 The *Tractatus* needs to ascribe features of another sort to objects in order to allow for colours and other properties which Wittgenstein calls 'material' (*T*2.0231). Since it is impossible for 'two colors to occupy the same place in the visual field' or for a particle to have two different velocities or spatial positions at the same time (*T*6.3571) being red and being blue (being here and being there, having this velocity and that velocity) exclude one another and therefore cannot *all* be states of affairs. It is plausible that according to the *Tractatus* none of them are. Colour, velocity and position are material properties and it is 'only by the configuration of objects that…[material properties]…are constructed *(gebildet')* (*T*2.0231). Thus, the fact that my Dodger cap is Dodger blue should reduce to

> complex situations made possible by the natures (concatenation abilities) of the objects they involve. The natures of the relevant objects must also rule out complex situations which would give my cap different colours (or give its colour different degrees of brightness) all over at the same time. This is an example of how 'empirical reality is limited by the totality of objects' (*T*5.5561A). I will call the features of objects which make possible and constrain the material properties of familiar things 'material capacities'.[60] These are, or should reduce to internal features of objects.

In the next section, I suggest that objects with no features but these cannot be discriminated one from another as required to understand their names.[61] If so, it will be impossible to interpret sentences used to picture states of affairs or complex situations. Because states of affairs are simply concatenations of objects, it will also be impossible (for theoreticians as well as speakers) to discriminate between states of affairs which constitute the truth grounds of different propositions. The meaning of a Tractarian name is exhausted by its reference to an object (*T*3.203) and elementary propositions are nothing more than names arranged to picture states of affairs which are nothing more than arrangements of the bearers of the names. Thus, it looks as though we will not be able to determine the truth conditions of elementary propositions. That makes it hard to see how we could construct (or interpret constructions of) their non-tautologous, logically consistent truth functions—including the truth functions expressed in technical and everyday natural languages. Over and above the fact that no construction is actually undertaken in the *Tractatus*, this makes it look as though the construction of any informal or technical natural language proposition would require considerable adjustments in its theory of objects.

XI TRACTARIAN ANTI-DISCRIMINATION

A first thing to say about this is that while Tractarian objects neither are nor possess material properties, these are the only features which our senses and instruments of observation and measurement are capable of registering or recording (at least in any form that we can recognize). Thus, there is no reason to think that our senses or our equipment can observe perceive, photograph or otherwise register or record any particular object or its features. If we have any empirical access to objects, it must be by way of the analysis of whatever states of affairs or situations we (and our equipment) can observe and record.[62]

The next thing to notice is that objects cannot be discriminated unless they have different features (*T*2.02331) and all features of

objects are external or internal (including material capacities). But even if we could pick out an object by way of its external features, they would not suffice for its re-identification. Setting aside the fact that our senses and our equipment are not attuned to objects suppose we could somehow examine single states of affairs and give the name 'a' to the object we find presently concatenated with another object, to which we give the name 'b'. This gives us one external feature of a and b—the fact that they are concatenated. But that will not enable us to recognize a in any other state of affairs. And even if it did, we would not be able to tell whether or not any other object concatenated with a in any other state of affairs (in this or any other world) is the object we originally called b. (Since we do not know any internal properties we have no reason to think a and b cannot belong to other states of affairs, and no idea of which ones they can belong to.) The fact that b was concatenated with a will not allow us to discriminate b from any other object concatenated with a in any other state of affairs. Thus, Wittgenstein seems to be quite right to say we cannot know an object unless we know its internal properties (*T*2.01231).

How could we detect the internal features of an object? If a and b are concatenated we know that they can concatenate with one another; that's one internal feature. But to find out what other internal features they have, we must find out what other objects they can or cannot concatenate with. Suppose we knew somehow that ac does not obtain, where c is yet another object, ac might fail to obtain because the concatenation is impossible. (That would be an internal feature of a and c.) But its non-obtaining could be just a contingent fact (external feature). To decide between these possibilities, we would have to find out whether ac obtains in any non-actual world. But there is no way to find that out unless the objects have marks which enable us to identify them across worlds. External features are limited to properties objects have in the actual world, and so they cannot serve this purpose. Internal features (including material capacities) would do the job, but they cannot be detected without marks by which objects can be identified across worlds. If we cannot detect the internal features which distinguish a from b, we will not be able to discriminate state of affairs ab from ba, or be, where c is any other object you please.

If (as seems impossible) we had some way to assign names (i.e. signs to be used as names) to objects belonging to actual facts, we might try to avoid trans-world identity questions by stipulation. For example, in thinking about how the object concatenated with b in this world might be situated in other possible worlds, we would give it a name and stipulate its inclusion (under the same name) in the relevant alternative worlds. On this approach possible worlds are constructed by the theoretician, and their contents are '*stipulated*, not *discovered* by powerful

telescopes'.[63] But because states of affairs are completely independent, there are any number of possibilities for different systems of stipulations. We could not discriminate between different objects called by the same name and states of affairs portrayed by the same sentence under different stipulations. But Wittgenstein was a realist about objects; according to the ontology of the *Tractatus* our inability to detect their differences would not make the differences any less real. The *Tractatus* considers no such possibility, let alone how such stipulations might be constrained.

If the identities of objects rest on stipulation, so do the senses of elementary propositions. Different stipulations will allow the same propositions to be analysed as truth functions of different elementary propositions. Under different stipulations material properties will reduce to deployments of different objects. This need not sound so bad from the standpoint of model semantic techniques which do not require discriminations to be made among all of what the *Tractatus* would count as different collections of possible worlds. But this is not Wittgenstein's point of view; the relevant semantic techniques were developed after the *Tractatus*.

It need not sound so bad from the standpoint of programmes of reduction and construction developed by the logical positivists. These programmes allow the theoretician's purposes to dictate the choice of items to be treated as objects. For example, although Carnap's epistemological concerns led him to choose 'experiences' as the basic elements of the *Aufbau,* he thought that given other interests, 'physicalistic' items could have been treated as basic.[64] Wittgenstein rejected this approach, at least in so far as the choice of basic elements involves stipulations or assumptions concerning the forms of elementary propositions. In 1931 he said it had always been clear to him that 'we cannot assume from the very beginning, as Carnap, does, that the elementary propositions consist of two-place relations, etc'.[65]

It is ironic that such construction programmes are still commonly associated with the *Tractatus*. It is historically important that their treatment of objects, states of affairs, and the interpretation of names and elementary propositions is profoundly non-Tractarian.

XII THE MEANING OF LIFE, THE UNIVERSE, AND EVERYTHING

If Wittgenstein did not mind the incompleteness of the *Tractatus* treatment of topics so many readers believed it taught them about, what did he want his book to accomplish? Its preface (echoed by its closing

line) says what the *Tractatus* shows is that the posing of philosophical problems:

> rests on the misunderstanding of the logic of our language. One could capture *(fassen)* the whole sense of the book in something like the words: What can be said at all can be said clearly; and that whereof one cannot speak, thereof one must be silent.
>
> ([4.45], 3; cp. p. 7)

This applies, for example, to 'mystical' questions about why there is a world (*T*6.44), the nature and concerns of God (*T*6.432) and the source of ethical and aesthetic value. (*T*6.41–6.421) It applies to questions about the meaning of life (*T*6.52) and why we should do what is good rather than what is wrong (*T*6.422). It applies to questions raised by philosophical skepticisms (*T*6.51), solipsisms and realisms (*T*5.62–5.641). Propositions can represent everything which can be the case (*T*3, 4.12A). But philosophical problems are not questions about what is the case (*T*6.52, 6.4321, 4.1, 4.11). For the *Tractatus,* philosophy properly understood is an activity aimed at resolving problems by the clarification of thoughts, rather than a body of doctrine (T4.112ff.). The *Tractatus* and Wittgenstein's later works agree as much on this as they disagree about the nature of the activity.[66]

For the *Tractatus* a crucial part of the activity would involve setting out propositions in a logically perspicuous symbolism (*T*4.1213) which reveals the essential features of the relevant symbols which must be exhibited to clear away a philosophical problem. There are illustrations of this for the case of problems whose resolution does not require us to construct natural language propositions, use names for objects or grasp the truth conditions of elementary propositions. For example, the notation for joint negation resolves questions about what sorts of things such logical constants as '¬','⊃', '&' represent by showing that the expression of truth functions does not require these signs to represent anything (*T*4.0312, 5.4). Similarly for any p and q, the connections between the truth grounds of q and (p & **p⊃q**) which explain why the latter entails the former can be exhibited without interpreting any elementary propositions. This allows Wittgenstein to dissolve questions generated by the assumption that *modus ponens* reports very general extra-linguistic facts—and similarly for other logical laws (see section VIII above).

Wittgenstein thinks the cure for these and all other philosophical problems (including the mystical ones) lies not in what propositions *say,* but rather, in what is *shown* by various uses of signs—including the use of logically perspicuous notations to say the same things as less perspicuous ones. The employment of signs shows what the signs fail to say (*T*3.262). While the employment of signs tells us *(spricht)* 'what the signs conceal'

(*T*3.262) it does not literally say it: 'what *can* be shown *cannot* be said.' (*T*4.1212). It looks as though these ineffables are conveyed in a number of different ways. For example, although we cannot say of a proposition (symbol) that it has such and such a sense, the proposition shows us what its sense is by picturing it (*T*4.022). But presumably if the way Newtonian mechanics allows us to describe the world shows us something about world, it does not show us in the same way (*T*6.342)—or in the same way that a proposition displays its pictorial form (*T*2.172). All that these and other sorts of showings need and have in common is (a) that what is conveyed is not the obtaining and non-obtainings of states of affairs, and (b) that it is not conveyed in the same way that a proposition expresses its sense.

A particularly important kind of showing is required for the sentences of the *Tractatus* which Wittgenstein says 'clarify' *(erläutern)* the functioning of language even though they are 'nonsensical' (*T*6.54). This includes, e.g., the sentences which present the picture theory, the ontology and the method of construction by joint negation. It would include any locution offering any semantical or syntactical analysis. Wittgenstein's treatment of identity illustrates the difference between this and another sort of showing. 'Roughly speaking, to say of *two* things that they are identical is nonsense' (*T*5.5303). This does *not* mean such expressions as 'a=b', '$\forall x(fx \supset x = a)$' convey nothing. Instead, they convey what they convey by showing rather than saying it. But the employment of a notation with no identity sign can show the same thing in another way which 'also disposes of all the problems that were connected with such pseudo-propositions' (*T*5.535). A. logically perspicuous notation would employ exactly one name for each object. The differences between the names would dispense with the need to write down any thing like 'a=b' (*T*5.53). The number of different names would show the same thing a non-perspicuous notation would show (in a different way) by means of such nonsense expressions as 'there are (are not) infinitely many objects' (*T*5.535). And it would show us that identity is not a relation if it provided a way to analyse identity signs away from formulas which contain them.[67] This—as opposed to the showing done by some nonsense sentences—is the sort of showing illustrated by the use of joint negation to show that the logical constants do not represent and that the justification of an inference does not depend upon laws of logic (above). Wittgenstein appeals to these (and other sorts of showing) in hopes of avoiding the need for a hierarchy of languages, each one of which is described by expressions belonging to the next language up. Instead of constructing a metalanguage to *say*, e.g., that 'ab' is true just in case a is concatenated with b, Wittgenstein's idea was that this could be *shown* by nonsense sentences in the same language we use to say 'ab' or by features of that language. In effect, Wittgenstein

appeals to different ways of communicating (saying and showing) in place of metalanguages constructed to describe object languages.

But I do not think this is the only, or the most important, motivation for the doctrine of showing. Wittgenstein was deeply concerned with mystical issues including those the logical positivists called 'metaphysical' and hoped to eliminate by employing methods they believed the *Tractatus* contained. Carnap said Wittgenstein gave him the 'insight that many philosophical sentences, especially in traditional metaphysics are pseudosentences devoid of content'.[68] This sounds like something you could learn from the philosopher who wrote that because answers to '*all possible* scientific questions' would leave the 'problems of life… completely untouched…there are then no questions left, and this itself is the answer.' (*T*6.52).

But Wittgenstein wrote to an editor to whom he had submitted the *Tractatus* that its 'point is an ethical one'. It consists, he said:

> of two parts: the one presented here [i.e., the complete text of the *Tractatus*] plus all that I have *not* written. And it is precisely the second part that is the important one… I believe that where *many* others today are just *blathering (schwefeln)* [about the sphere of the ethical] I have managed…to put everything firmly into place by being silent about it.[69]

This suggests that when Wittgenstein spoke of the vanishing of mystical problems (*T*6.521) all he really meant was the vanishing of the blather about them. He says 'the sense of life' has become clear to people after long periods of doubt even though 'they have been unable to say what constituted that sense' (*T*6.521)[70] Far from denying the reality of what these people could not express, the next passage affirms it: 'there are, indeed things that cannot be put into words. They show themselves. They are the mystical' (*T*6.522).

In contrast to these, what we can say, namely: '…*[h]ow* things are in the world is a matter of complete indifference for what is higher' (*T*6.432).

Wittgenstein seems to have felt that what can be said is insignificant in comparison to what can be shown.[71] If this is so, what Wittgenstein's readers thought they learned was not what he hoped to teach. The *Tractatus* exerted its greatest influence through the works of empiricists who thought that what cannot be said is nothing at all. They believed that what is important can be discovered and expressed by the natural sciences. They believed the mystical concerns of the unwritten part of the *Tractatus* were delusions. They valued the *Tractatus* as a cache of weapons to combat them.[72]

NOTES

1 [4.45]. The original title was *Logisch-Philosophisce Abhandlung*. The title *Tractatus Logico-Philosophicus* was suggested by G.E.Moore. For a composition and publication history, see [4.48], 1–33, 255ff. For the history and circumstances of its composition, see [4.22] chs 7–8 and [4.23], chs 5–8.
2 Numbers in parentheses marked *T* are *Tractatus* section numbers.
3 Wittgenstein's usage differs from Russell's. For Russell, G.E.Moore's having recorded with Thelonius Monk is a negative fact. For Wittgenstein it is not a fact of any kind and the relevant negative fact is that Moore did not record with Thelonius.
4 I use 'world' for what [*T*2.06] calls 'reality'; Wittgenstein's worlds include only positive facts.
5 Wittgenstein wrote a version of the truth table in 1912 on the back of a paper Russell presented to the Cambridge moral sciences club [4.22], 160. Quine says truth tables were used to set out truth functions independently of the *Tractatus* in papers by Lukasiewicz, and Post in 1920–1, and that Peirce described a non-tabular version of essentially the same method in 1885 [4.26], 14.
6 For example since N (3) has the same truth conditions as (2), we had best pick another once we have got (3). For a complete discussion for the case of two elementary propositions see [4.1], 133ff.
7 See [4.38], 480ff.
8 For details, see [4.1], 135ff.
9 [4.24], 297.
10 Cp. [4.1], 133–4.
11 [4.2], 312. We need the next steps because merely to select p as a value of is not to construct it by joint denial.
12 [4.47], section 94.
13 For a discussion of this problem for the case of quantified propositions, see [4.19].
14 A model according to von Wright; a diagram according to Malcolm. [4.21], 8, 57.
15 Cp. [4.46], 7, 27.
16 Cp. [4.37], [4.38].
17 [4.47], Section 94.
18 [4.25], 321. Anachronistically speaking, to judge 'one thing' is to believe something definite enough to determine the truth conditions of the belief. Wittgenstein's quotation of some of this in connection with picturing at [4.47], section 518, makes it plausible (without proving) that he knew the passage when he wrote TS. For another version of the argument see [4.3], 6ff.
19 [4.28], 28–33, [4.30], 528–33, [4.35], 193ff.
20 [4.6], 144.
21 [4.31], ch. XII, [4.34], 43, [4.36], part II, chs i-iii.
22 [4.12], 56–78. For a concise statement of Frege's version of the problem, see [4.14], 117ff. See also [4.1].
23 [4.14, 127].
24 For example, if there is no such person as Odysseus, the name 'Odysseus' lacks a reference and propositions like 'Odysseus was set ashore at Ithaca…' have sense but no reference [4.12, 63].

25 [4.12]. This ignores many important details, most notably Frege's treatment of indirect reference.
26 See [4.8], 197, 280–1.
27 The last sentence of 4.442 rejects (and mis-states) Frege's idea that to assert a proposition is to commit oneself to its naming the True. For other points of contact with Frege, see [4.2], 182–3.
28 [4.3], 104ff.
29 The constituents of Russell's propositions are not the constituents of Tractarian states of affairs. For example, (section X) Russellian objects are sense data, not Tractarian simples and Tractarian situations contain no relational constituents. For this and other differences between Russellian and Tractarian atomism see [4.4], ch. 1.
30 Russell depends upon the theory of descriptions to analyse judgements which seem to involve non-existing things. Thus my judgement that unicorns live outside of Boulder, Colorado, relates me not to non-existent unicorns—but to a collection of existing things at least one of which would be a unicorn *if* my judgement were true.
31 [4.22], 174. Wittgenstein's pressing of this point was not only decisive, but remarkably harsh. In 1916 Russell wrote to Ottoline Morrell that they 'affected everything I have done since. I saw he was right and I saw that I could not hope ever again to do fundamental work in philosophy. My impulse was shattered like a wave…against a breakwater'. [4.22], 174–7.

The following from a letter to Russell from Austria in 1913 is a good place to start trying to imagine what it might have been like to be personally involved with Wittgenstein.

> The weather here is constantly rotten, we have not yet had two fine days in succession. I am very sorry to hear that my objection to your theory of judgement paralyses you. I think it can only be removed by a correct theory of propositions.
>
> ([4.49], 24)

32 I assume Wittgenstein is using 'proposition' here for collections of objects to which Russell thought judging relates the mind of the judger. This would accord loosely with both Russell's and Moore's usage during this period.
33 [4.27]. 13.
34 Cp. 3.11: If 'the method of projection' by which signs are used to picture possible situations is identical to 'the thinking of the sense of the proposition' and if the sense of the proposition is that such and such is the case, then judging, thinking, believing, etc. that such and such is the case should be reducible to the relevant uses of signs. A 1919 letter to Russell says that the elements of the thought are 'psychical constituents which have the same sort of relation to reality as words', [4.49], 72.

Wittgenstein's analysis has its problems. Wittgenstein does not say what 'p' has to do with the person who judges, thinks, etc., that p. Thus, if all claims of the form 'A believes p' are to be analysed as '"p" says p', how is the analysis supposed to capture the difference between the claim that Thelonius believes p and the claim that Bud believes p? What sorts of signs are involved in judging? Ramsey thought (quite plausibly) that they should belong to some sort of mentalese, but Wittgenstein does not go into this. Presumably, we can say that Thelonius believes that p, and what we

say is contingently true or false. But the *Tractatus* seems to treat such claims as that such and such proposition has such and such a sense as unspeakable, and what is unspeakable should not be contingently true or false.

35 See note 43.

36 This would be much easier to understand if it were a matter of syntactical constraints on signs than it is to understand in connection with Tractarian symbols.

37 See [4.41], 1–36 for an enlightening discussion of this and the importance of Frege's approach.

38 [4.17], 109.

39 [4–6], 145–6.

40 Cp. [4.45], Shwayder discusses this in detail, suggesting that part of Wittgenstein's point (at *T*3.5) in calling the applied propositional sign *der Gedanke* (which should be translated '*the* thought', rather than '*a* thought') and then saying that the thought is the meaningful proposition (4), was to show how he proposed to get along without the Fregean sense ('the thought') [4.38], vol II, 4–7).

41 [4.36], 115.

42 cp. [4.34], 93.

43 For example, the ratio of truth grounds common to and p&¬q (there are none) to truth grounds of p&¬q is true is . Since tautologies are true in every world, their probability is 1, given any non-contradictory proposition. Wittgenstein does not tell us what to do about the fact that the probability of any proposition given a contradiction will be .

44 Or so it seems; see section XI.

45 Not only in *Tractatus,* but also in discussion from 1927 on, and as expanded and modified by Waismann in 1929 [4.5], 71ff.

46 [4.44], 33, 35.

47 Cp. [4.43], 93.

48 For example, by requiring every probability to equal 0, 1, or some number in between.

49 Cp. [4.2], 256.

50 It is important that Wittgenstein's conventionalism does not require him to think that developing, accepting or using a scientific theory requires anyone actually to find out what states of affairs there are and decide how to group them, or to inspect the elementary propositions and decide which sorts of truth functions to construct from them. The construction of truth functions and complex situations is something the scientist must accomplish in order to do his work. But just as people can speak without having any idea of which muscles must be made to contract in order for them to utter words, the scientist—like any other language user—can construct and employ languages to describe phenomena 'without having any idea of how each word has meaning or what its meaning is' (*T*4.002). This does not explicitly mention science but there is no reason to think it does not apply to scientific language.

51 I suppose 'the precise way' involves, e.g., how the Newtonian physicist must think of time and space, what he must do, e.g., in choosing and employing a reference system to locate bodies in the space and describe their motions—as well as what must be done to calculate values of such quantities as Newtonian force, acceleration and mass from observational data, what kinds of computations are required for prediction, etc. See [4.2], 354–60.

52 See, for example, [4.50], 5–7, 10, 17, 27, 62, 63, and [4.23] ch. 23.
53 [4.1], 25–9.
54 4.062 is typical of what little he does say on such subjects: it contrasts propositions which we can understand without having their senses explained with 'the meanings of the simple signs (the words)' which cannot be understood without explanation. But he has just said that foreign language dictionaries help us translate propositions by translating 'substantives,…verbs, adjectives, and conjunctions, etc.', rather than whole propositions (4.025). Since these are not Tractarian names, it is not clear whether 4.062 is a remark about Tractarian names.
55 [4.46], 65
56 [4.42], Vienna Circle, pp. 233 ff. Among other things, this includes the 'verification theory', (one of the most important ideas attributed by the logical positivists to Wittgenstein) in the form of the claim that 'a proposition cannot say more than is established by its method of verification' and that 'to say that a statement has sense means that it can be verified' (p. 244). No such thing occurs in the *Tractatus*. But cp. 'On Dogmatism' (1931) in which Wittgenstein decides that writing the 'Theses' was not such a good idea after all [4.43], 182
57 [4.46], 60, 67
58 Ibid., 60, 62
59 Constituted for example, by the way states of affairs an object belongs to are collected into complex situations
60 This may explain why 'space, time, and color…are forms of objects' (2.0251). Even though Tractarian objects neither are nor have colours Wittgenstein may think that certain objects figure uniquely in states of affairs which determine colour possibilities, and have colour as their form in just this sense. Similarly, objects which figure uniquely in the construction of (physical) spatial facts could be said to have space as their form even though they are not themselves either physical spaces or spatial objects.
61 [4.16], ch 2 is an excellent (and as far as I know, the first) discussion of difficulties in the individuation of *Tractatus* objects.
62 Ibid., 15–19.
63 [4.20], 44.
64 [4.5], 18.
65 [4.43], 182 This passage also eschews 'hypotheses' (i.e. 'law[s] for constructing statements' (p. 255) concerning elementary propositions).
66 This may be one reason Wittgenstein wanted the *Tractatus* and the *Investigations* to be published together [4.47], x.
67 Wittgenstein's example of replacing (1) '$\forall x(Fx \supset x = a)$' with (2) '$(\exists x)(Fx) \supset Fa) \;\&\neg(\exists x,y)(Fx\&Fy)$' (5.5321) is troublesome unless he can rule out the substitution of 'a' for both variables to obtain ' & ¬(Fa&Fa) as an instance of (2). For other issues involving the elimination of identity see [4.10], 60–9; [4.11], *passim*.
68 [4.5], 25.
69 Adapted from McGuiness' translation in [4.9], 143.
70 Wittgenstein's use of the word 'sense' is surely intended to make us contrast this sort of meaningfulness with the meanings of propositions.
71 [4.10], 90. [4.9] includes sympathetic and persuasive support for this reading.

72 My understanding and appreciation of Wittgenstein's early work has been greatly enhanced by conversation with and help from David Shwayder, Robert Fogelin, Jack Vickers, Jay Atlas, and David McCarty. I am also indebted to Howard Richner for spotting disasters in an earlier version of this chapter.

CHAPTER 5

Logical Positivism

Oswald Hanfling

I INTRODUCTION

'Logical positivism', writes a leading historian of twentieth-century philosophy, 'is dead, or as dead as a philosophical movement ever becomes' (Passmore [5.42]). Most philosophers today, and indeed for some time past, would endorse this statement. In one sense it is absolutely dead, for it lost its cohesive membership with the break-up of the group of philosophers known as the 'Vienna Circle', due to political pressures in the 1930s. It was here that the philosophy known as logical positivism had been initiated, developed and energetically propounded to the philosophical community throughout the world.

The 'death' of the movement was due, however, not only to the dispersal of its members, but also to a widespread recognition of the defects of its ideas. Now in this sense, probably most of the philosophy studied in our universities is dead, for most of it is open to more-or-less fatal criticisms; and criticism is regarded as one of the main approaches to the great philosophers and movements of the past. However, what hastened the widespread rejection of logical positivism was not merely the (unsurprising) discovery that its doctrines were open to criticism, but the aggressive and even arrogant way in which those doctrines were propounded to the world. Chief among these was the 'elimination of metaphysics'. It was claimed by members of the movement that they had noticed something about existing and traditional philosophy, which would completely overturn it and render it largely otiose. There appeared articles with such titles as 'The Elimination of Metaphysics through the Logical Analysis of Language' (Carnap [5.5]) and 'The Turning Point in Philosophy' (Schlick [5.24]). Carnap posed the question: 'Can it be that so

many men, of various times and nations, outstanding minds among them, have devoted so much effort, and indeed fervour, to metaphysics, when this consists of nothing more than words strung together without sense?' International conferences were called with a view to disseminating the new 'insights', and a grandiose project, *The Encyclopedia of Unified Science,* was launched to give definitive expression to the new 'scientific' era in which philosophical and other discourse would become part of the discourse of science. In these circumstances it was not surprising that critics of the new ideas were more than usually prompt, forthright and thorough in their criticisms.

Nevertheless, logical positivism has an established place in the history and continuing development of philosophy. At least three reasons might be given for this. One is purely historical, regarding the considerable impact and influence of the movement in its heyday. A second lies in the intrinsic interest of its ideas, which I hope to bring out in what follows. A third lies in the fact that even if no one today would call himself a logical positivist, some of its main positions, such as verificationism, and emotivism in ethics, are still referred to as parameters within which discussions of particular topics, such as ethics or the philosophy of religion or of science, are to be conducted. Again, it can be argued that even if the parent plant is dead, many of its seeds are alive and active in one form or another. In an interview in 1979, A.J.Ayer, a leading philosopher of our time, who had been an advocate of logical positivism in the 1930s, was asked what he now saw as its main defects. He replied: 'I suppose the most important…was that nearly all of it was false'. Yet this did not prevent him from admitting, shortly afterwards that he still believed in 'the same general approach' ([5.70], 131–2).

In a number of ways 'the same general approach' is still widespread today, and indeed was so long before the advent of logical positivism. Empiricism, in one sense or another, is a major thread running through Western philosophy since the seventeenth century, including logical positivism and much of the philosophy of today. The same is true of 'reductionism', and especially the assumption that mental phenomena can be reduced, in some sense, to the vocabulary of the material or physical. Another idea, which was central to logical positivism and remains of central importance today, is that philosophical questions are largely questions of language, and that theories of meaning are therefore of central importance.

The movement originated in the 1920s among philosophers and scientists of the 'Vienna Circle', under the leadership of Moritz Schlick, professor at the University of Vienna. After some years of writing and discussion, the Circle organized its first international congress in 1929, attracting sympathizers from many countries. In 1930 it took over a journal, renamed *Erkenntnis,* for the publication of its ideas. The British

philosopher A.J.Ayer attended its meetings in 1933 and made its ideas widely known in the English-speaking world with the publication of *Language, Truth and Logic* in 1936 [5.1].

By that time the dispersal of the Circle was already under way, a number of members having emigrated, mainly to the United States and Britain. But there were also fundamental intellectual differences within the Circle. One of these, between Schlick and Carnap and Neurath, will be described below in section V.

An important influence was that of Wittgenstein, though he was not a member of the Circle. Having retired from philosophy after the publication of his *Tractatus Logico-Philosophicus* in 1922 [5.28], he was coaxed back into the subject by Schlick in 1927 and had regular meetings with Schlick and Waismann, another member of the Circle. (Their conversations are recorded in [5.27].) But from 1929 he declined to meet with other members of the Circle, whose views he found unsympathetic—a sentiment that was reciprocated by Otto Neurath, for one. Nevertheless, the *Tractatus* was regarded by the Circle as a classic statement of the new outlook in philosophy, and the work was read out and discussed sentence by sentence in the period 1924–6. It was, moreover, Wittgenstein who first formulated the 'verification principle' by which the new philosophy became known. Nevertheless it was he who made the most decisive break from these ideas when embarking on his 'later' philosophy in the early thirties.

The philosophy of the Circle became known as 'logical positivism' or 'logical empiricism'. The former name is more usual, but the latter, preferred by Schlick, seems to me to be more appropriate. It has the advantage of indicating the affinity of the Circle's ideas with those of the empiricist tradition begun by Locke in the seventeenth century, and later represented by such thinkers as Mill and Russell. It is also readily connected with the Circle interest in empirical science. Hence, although this article is entitled 'logical positivism', I shall prefer to use the term 'logical empiricism'.

The term 'logical' indicates a primary interest in language and meaning, as opposed to knowledge. The main questions for such philosophers as Locke and Descartes had been about the sources and extent of knowledge, and the empiricist Locke claimed that sense experience was the only source. In the new empiricism, by contrast, the primary question was not 'How do we know that *p*?', but 'What does "p" mean?'

The new approach may be illustrated by the problem of 'other minds'. How can I know that other people really have thoughts and feelings, when I can only observe their bodily movements and the sounds they utter? In the new philosophy this problem of knowledge is transformed into one about meaning. What does it *mean* to say that another person has such and

such a feeling? According to the new philosophy, it can mean *no more* than what is observable. Any statement about feelings as distinct from what is observable will be meaningless. 'It is not false, be it noted, but meaningless: we have no idea what it is supposed to signify' ([5.24], 270).

The logical empiricists recognized two, and only two, kinds of meaningful statements. They are, first and mainly, empirical statements, verifiable by observation. Second, there are statements, such as those of logic and mathematics, whose truth can be known a priori; but these were regarded as not presenting 'new' knowledge, but merely an analysis of what was known already. Any other statements were to be dismissed as meaningless 'pseudo-statements'.

II THE VERIFICATION PRINCIPLE

'The meaning of a proposition is the method of its verification.' So ran the principle as formulated by Wittgenstein and Schlick. (It was first formulated by Wittgenstein, but its most frequent use occurs in the writings of Schlick.)

In this sentence we have an answer to a long-standing question of philosophy, namely, What does meaning—the kind of meaning that language possesses—consist in? This question has sometimes been answered in terms of words and sometimes in terms of sentences or speech-acts. Locke answered it by reference to mental entities corresponding to words, claiming that 'words…signify nothing but the Ideas that are in the mind of the speaker' [5.78], 3.2.4). Wittgenstein, in the *Tractatus,* had postulated 'names' as the fundamental units of meaning, these 'names' being correlated with fundamental 'objects' in the world; with a further 'picturing' relation between propositions and corresponding 'states of affairs' in the world. The verificationist answer, as I have said, was in terms of the method of verification of a given proposition. Here was an apparently simple principle which could provide a focus for both adherents and critics of the new movement.

As well as providing an answer to the question 'What is meaning?', the principle was intended to provide a criterion to distinguish what is meaningful from what is not. Thus, if there is *no* method of verification—no way of verifying the proposition—then it must be meaningless.

It seems obvious that there is something right about the verification principle; that there is, at least, an important connection between meaning and verification. Thus, if we are unsure what someone means by his words, we can often find out by asking how one would verify what he said. And sometimes, at least, the admission that there is no conceivable method of verification will lead us to conclude that what was said is meaningless.

On the other hand, there are a number of difficulties with the principle, which may be divided into three, corresponding to the terms 'proposition', 'is' and 'method of verification'.

The original German word for 'proposition' is *Satz,* and the straightforward translation of this is 'sentence'. There is a difficulty, however, about treating sentences as objects of verification. Such a sentence as 'It is raining' cannot be regarded as true or false in itself. It is only when someone *uses* the sentence on a particular occasion that *what he says* is true or false. In answer to this and other difficulties philosophers have used the term 'proposition' to mean, roughly, what is asserted by means of a declarative sentence. It is, according to this usage, propositions that are true or false, and not the sentences by means of which they are asserted.

But now another difficulty may arise. 'Proposition' is sometimes defined as meaning an entity that is necessarily true or false. But if this is so, then the question of meaningfulness has already been decided in using the term 'proposition', for only what is meaningful can be described as true or false. In other words, it would be self-contradictory to speak of a meaningless proposition.

One way of overcoming this would be to put 'putative' before 'proposition'; another, which I shall adopt, is to use the word 'statement'. In ordinary English we can ask of a statement, made by someone, both whether it means anything and, if so, whether it is true. Some philosophers have also defined 'statement' to mean what is necessarily true or false (and hence meaningful), but there is no need for a verificationist to follow this usage. In this article I shall prefer the word 'statement', but will sometimes follow the writers under discussion in using 'sentence' or 'proposition', as the case may be. This seems the least confusing way of proceeding. (For further discussion of the difficulty about sentences and propositions, see [5.59] and [5.42].)

My next difficulty was about the word 'is', in the claim that meaning 'is' a method of verification. How are we to understand this identification? 'Meaning' and 'method' are concepts of different types. 'One can sensibly talk about *using* a method, but [not] "using a meaning"' ([5.52], 36). A method may be easy or difficult to carry out, it may take a long or a short time, etc.; but these things cannot be said about the meaning of a statement.

Nevertheless, it was thought essential to account for the meaning of verbal expressions by reference to something other than verbal expressions. Otherwise what would be the connection between language and reality? This need was expressed as follows by Schlick:

> in order to arrive at the meaning of a sentence or proposition we must go beyond propositions. For we cannot hope to explain the

> meaning of a proposition merely by presenting another proposition… I could always go on asking 'But what does this new proposition mean?'… The discovery of the meaning of any proposition must ultimately be achieved by some act, some immediate procedure.
>
> ([5.24], 219–20)

A similar thought was sometimes expressed with reference to words as distinct from propositions, and here the notion of 'ostensive definition' (as distinct from verification) was invoked, as when we point to an object to explain the meaning of a corresponding word, such as the word 'red'. Wittgenstein expressed this thought as follows: 'The verbal definition, as it takes us from one verbal expression to another, in a sense gets us no further. In the ostensive definition however we seem to take a much more real step towards learning the meaning' ([5.79], 1). This passage, however, was written after Wittgenstein's break from verificationism, and in the ensuing pages he argued that such appeals to 'reality' as distinct from language could never supply the desired detatchment from language. He imagined someone trying to explain the word 'tove' by pointing to a pencil and pointed out that, in the absence of all verbal information, this act might be taken to mean all sorts of different things.

This brings us to the third difficulty; about 'method of verification'. What would be the relevant method in the case of, say, the statement 'It is raining'? I might verify this by putting my hand out of the window. But this act might serve to verify all sorts of statements; and, on the other hand, all sorts of methods might be used to verify the statement.

I began with a difficulty about identifying meaning with a method, as indicated by the word 'is' in the verification principle. Suppose now that we removed this word and spoke instead of a 'correspondence' between meaning and method. This would still leave us with the difficulty just mentioned. It is hard to see how Schlick's requirement of 'going beyond propositions'—breaking out of the circle of language—could ever be satisfied.

III THE CRITERION OF VERIFIABILITY

Not every verificationist was concerned, or mainly concerned, about the question of what meaning consists in. One of the main aims of the movement, as I said, was to distinguish what is meaningful from what is meaningless, with the special aim of showing statements of metaphysics to belong to the latter class. Now such a criterion can easily be deduced from the verification principle. If the meaning of a

statement is the method of its verification, then it will follow that if it lacks such a method—if it is not verifiable—then it will, likewise, lack meaning. It is possible, however, to advocate this criterion independently, without deduction from the verification principle. Thus, one might claim that unverifiable statements are meaningless, without putting forward an account of what meaning consists in; and this was the position of A.J. Ayer. He expressed the *criterion of verifiability*, as I shall call it, as follows:

> We say that a sentence is factually significant to any person if, and only if, he knows how to verify the proposition that it purports to express—that is, if he knows what observations would lead him, under certain conditions, to accept the proposition as being true, or reject is as being false.
>
> ([5.1], 48)

(Sometimes the term 'verification principle' has been used for the criterion of verifiability, but the two tenets should not be confused.)

It should be noted that the word 'verify' is used here in the sense of 'verify whether…' and not 'verify that…' The latter would presuppose that the proposition in question is *true*. But a proposition that is known to be true is, by the same token, known to be meaningful; so that the criterion would be redundant. The relevant sense of 'verify' is that in which this is *not* known, so that, as Ayer implies, we do not yet know whether the proposition will turn out true or false. Moreover, either of these results would satisfy the criterion: what is at stake is not the truth of the proposition, but whether it has meaning. Unverifiable propositions, being meaningless according to the criterion, would be neither true nor false.

By means of such a criterion it was hoped to proceed immediately to the 'elimination of metaphysics', without getting involved in questions about what meaning consists in. The discovery that the propositions in question are meaningless would explain why philosophers who had wrestled with them through the ages had never, apparently, succeeded in getting anywhere, while, at the same time, providing the key to a resolution of their problems.

It soon appeared, however, that the criterion was beset with difficulties. First, there is simply the question of acceptance. In a broadcast debate with F.C.Copleston, A.J.Ayer introduced the word 'drogulus' to stand for 'a disembodied thing' whose presence could not be verified in any way. He put it to Copleston: 'Does that make sense?' But Copleston replied that it did make sense. He claimed that he could form an idea of such a thing and that this was enough to give it meaning ([5.50], 747).

Second, it proved difficult to formulate the criterion in such a way as to yield the desired results—to exclude the statements of metaphysics while admitting those of 'science' (including everyday empirical statements). The formulation I quoted from Ayer was too weak, because all sorts of observations might 'lead' someone to regard a proposition as true or as false. In a further formulation he introduced the more rigorous notion of 'deduction'. A statement is meaningful, he held, if 'some experiential propositions can be deduced from it', the latter being defined as propositions 'which record an actual or possible observation' ([5.1], 52). A typical example would be 'This is white', which might result from the fact that it is snowing. But while it is clear that this fact and this statement are related, the relation does not seem to be one of deduction. There is, for example, no logical deduction from the statement 'It is snowing' and, say, the fact that I am looking out of the window, to the conclusion that 'this is white', or the conclusion that I am seeing something white.

Suppose, however, that this difficulty could be resolved. In that case 'It is snowing' would be vindicated because 'This is white' is deducible from it. But clearly there is more than that to the meaning of 'It is snowing'. And might not the remainder be merely pseudomeaning, for all that Ayer's criterion has shown? This difficulty was illustrated in a striking way by Carl Hempel, who supposed that some straightforward empirical statement, such as 'It is snowing', had been *conjoined* with a piece of 'metaphysical nonsense', such as 'The absolute is perfect'. This conjunction would yield the same deductions as the empirical component by itself; so that the conjunction as a whole would have to be declared meaningful ([5.14]).

Various formulations were attempted by Ayer and others to escape these and other difficulties, but it seems that what is required is not merely deduction, but *analysis*. There must be a way of showing that the *whole* meaning of a statement is, somehow, accounted for by observations and the corresponding observation statements. Moreover, as we shall see, this affects all kinds of ordinary statements and not just the rather fanciful example constructed by Hempel.

IV ANALYSIS

According to Waismann, ordinary empirical statements were to be analysed into 'elementary propositions', whose whole meaning would consist in corresponding verificatory experiences.

> To analyse a proposition means to consider how it is to be verified. Language *touches* reality with elementary propositions… It is clear

> that assertions about bodies (tables, chairs) are not elementary propositions… What elementary propositions describe are: phenomena (experiences).
>
> ([5.27], 249)

There is a difference between this and verification in the ordinary sense. The latter is an activity of some kind, and hence it made sense to speak of a *method* of verification. But what seems to be meant in the passage just quoted is that elementary propositions are to be verified by *having* the corresponding 'experiences', as distinct from any activity.

But how is such analysis to proceed? From the true statement that there is a table in my room, it would not follow that anyone is having a relevant experience, since there may not be anyone in the room. The view adopted, known as 'phenomenalism', allowed for this possibility. According to it, a crucial role is played by *hypothetical* statements, such as 'If someone were in the room, he would have such and such experiences'. But in what sense are such statements entailed by the statement under scrutiny? Even if I am in the room, and endowed with normal eyesight, I may fail to see the table. 'You can't miss it' is notoriously unreliable.

There was also a difficulty about entailment in the other direction. From the fact that I am having the experience of seeing something brown, etc., it would not follow that there is a table in the room; and neither would it follow from my having the experience of seeing *a table*, for I might have these and other experiences in the course of a dream or hallucination. Just how far this kind of scepticism may be taken is a matter for debate, but the sceptical view is encouraged by the empiricist reliance on 'experience', conceived as something that occurs in us, is 'imprinted by the senses', etc. This problem has been recognized from the beginnings of empiricism, and in the case of logical empiricism it led to the view that statements about tables and chairs are not 'conclusively' verifiable. Wittgenstein spoke of them as 'hypotheses' which could not be 'definitively verified' ([5.80], 282–5).

A similar development took place with regard to general statements, such as 'All men are mortal'. The 'all men' in this statement is not analysable into any finite conjunction of names, and the truth of the statement would not follow from any finite number of verificatory experiences. The same is true of scientific laws, such as 'Water expands below 4°C', whose meaning is not confined to any finite number of observations.

The discovery that the meaning of scientific laws, in particular, went beyond any finite verification, was especially serious for a philosophy which regarded scientific statements as paradigms of meaningful discourse. One solution, advocated by Schlick, was to deny that a

scientific law is a statement: it is really, he maintained, 'an instruction for the forming of statements'. A genuine statement must be 'conclusively verifiable', and this would be true only of the particular experiential statements which would be produced under that 'instruction'. A statement, he insisted, 'has a meaning only in so far as it can be verified; it only *signifies* what is verified and absolutely *nothing* beyond this'; there cannot be a 'surplus of meaning' beyond that ([5.24], 266–9).

Another approach was used to deal with statements whose verification is impossible for technical reasons. Consider a statement about the far side of the moon. When Schlick and Ayer considered this example, verification was impossible and, for all they knew, might always remain so. The same is true, for us, about speculations concerning life on other planets. But it would seem absurd to claim that whether such questions have meaning depends on the present technology of space exploration. The answer was to describe the relevant statements as 'verifiable in principle'. 'I know what observations would decide it for me, if, as is theoretically conceivable, I were once in a position to make them' ([5.1], 48–9).

But what should we say about scientific statements or theories whose meaning seems to go far beyond their verificatory content, even 'in principle'? Consider the statement that the universe is expanding, and assume that it is based on the observation of a 'red shift' in the light emitted from remote galaxies. It seems clear that the statement is not merely about red shifts. Yet such a 'reduction' of meaning seems to be required by the verificationist analysis. In this connection verificationists enlisted P.W.Bridgman's idea of 'operationism'. On this view, the meaning of statements about distant parts of the universe, for example, would indeed correspond to the relevant scientific 'operations'; there would be no more to it than that. This meant, as Bridgman pointed out, that ordinary words might change their meaning when used in a scientific context. The meaning of 'length', he claimed, 'has changed completely in character' in the context of astronomy. 'Strictly speaking, length when measured…by light beams should be called by another name, since the operations are different' ([5.4], 3).

A further difficulty arose about the analysis of statements about the past. The statement 'It rained yesterday' might be verified, in the ordinary sense, by present evidence including, perhaps, asking other people. But the statement obviously does not *mean* any of these present things ([5.67], 329). Ayer offered a variety of analyses in attempting to meet the difficulty, including the bold claim that the tense of a statement is not part of its meaning, so that there would be no difference of meaning between 'George VI was crowned in 1937', 'George VI is being crowned in 1937', and 'George VI will be crowned in 1937' ([5.1], 25, [5.3], 186).

V THE ELIMINATION OF EXPERIENCE

In one way or another, the analysis of different kinds of statements would lead to the ultimate 'elementary propositions', variously described as 'experiental propositions', 'observation-statements' etc., whereby, as Waismann put it, 'language *touches* reality'. At this stage the speaker or hearer passes from linguistic activity to the occurrence of a suitable experience or sensation which is supposed to give meaning to the words. But here arose a problem which produced a serious split in the ranks of the Circle. Experience and sensation are personal and in some sense private; must not the same be true, then, of meaning? On this view, the sentence 'I am thirsty', as Carnap argued, 'though composed of the same sounds, would have different senses when uttered by [different people]'. But what, in that case, becomes of the claims of science, and of language itself, to be communal activities? There was, thought Carnap, a ready way of disposing of such awkward questions. 'These pseudo-questions', he declared, 'are automatically eliminated by using the formal mode.' By the 'formal mode' he meant a discourse that confined itself to statements and did not try to go beyond these, to what he called 'the material mode'. There was, he held, no need to talk about 'the content of experience', 'sensations of colour' and the like; we should instead refer to the corresponding *statements,* which he called 'protocol statements'. These, and not the corresponding experiences, would occupy the fundamental role in the system—that of 'needing no justification and serving as the foundation for all the remaining statements of science' ([5.7], 78–83).

Carnap was uncertain about the form that these protocol statements should take, proposing such expressions as 'Joy now', 'Here now blue' and 'A red cube is on the table' (Ibid., 46–7). But Otto Neurath argued that such expressions could not be fitted into the system of science, unless the reference of 'now' and 'here', and the identity of the speaker, were known to others. He gave the following as a suitable example: 'Otto's protocol at 3:17 o'clock: [At 3:16 o'clock Otto said to himself: (at 3:15 o'clock there was a table in the room perceived by Otto)] ([5.17], 163). This example, however, is still not sufficiently purged of personal elements. We who read it today would not know where in the system to place '3:17' or 'the room'; and the same would be true of 'Otto', were it not for independent knowledge of who Otto was. But perhaps Neurath was indicating the way towards a still more complex kind of statement, which would be wholly independent of reflexive reference.

Now it is clear that Neurath's example is meant as a protocol statement, because the term 'protocol' is used in it. But, now that the connection with experience has been cut, what entitles it to this

designation? Why should such statements be regarded as 'needing no justification and serving as the foundation' of science? Neurath's answer was that there are, indeed, no statements having this status. 'No sentence', he declared, 'enjoys the *"Noli me tangere"* which Carnap ordains for protocol sentences' (Ibid., 164–5). To illustrate the point he asked the reader to imagine an ambidextrous person writing down two contradictory protocols at the same time.

After the elimination of experience, what becomes of verification and truth? Neurath proposed that we might think of the system of science as a kind of 'sorting machine, into which the protocol sentences are thrown'. When a contradiction occurs, a bell rings, and then some exchange of protocol sentences must be made; but it does not matter which (Ibid., 168). This conception of truth, known as the 'coherence theory', would strike most people as paradoxical and is open to various objections. An objection made by Schlick was that on this view we 'must consider any fabricated tale to be no less true than a historical report' ([5.24], 376).

Schlick, describing himself as 'a true empiricist' (Ibid., 400) was resolute in his opposition to the elimination of experience. 'I would not', he declared, 'give up my own observation propositions under any circumstances… I would proclaim, as it were: "What I see, I see"' (Ibid., 380). In a number of writings he tried to overcome the difficulty about the subjectivity of experience without giving up this cardinal tenet of empiricism. In one of them he maintained that statements have both a 'structure' and a 'content'. The former they share with corresponding facts; and 'my propositions express these facts by conveying to you their logical structure' (Ibid., 292). But there is also a private 'content', which 'every observer fills in' for himself, and which is 'ineffable' (Ibid., 334).

In this matter too, logical empiricism was anticipated in the writings of 'classic' empiricists. According to Locke, we commonly think that words have shared meanings, but this is a mistake, given that meaning is tied to mental entities which he called 'ideas':

> Though words, as they are used by men, can properly and immediately signify nothing but the Ideas that are in the mind of the speaker, yet [men]…suppose their words to be marks of the ideas in the minds also of other men, with whom they communicate.
>
> ([5.78], 3.2.4)

Locke accepted this difficulty rather lightly, claiming that it was not a serious obstacle to communication. Such a treatment may seem acceptable for a philosophy which concerned itself primarily with

questions of knowledge. But in the new *logical* empiricism the matter could not be passed over so lightly.

A further development, beyond the scope of this article, was the celebrated 'private language' argument of Wittgenstein's later work, in which he made a decisive break from empiricist ideas about language, arguing that the alleged 'private' meaning would not be meaning, in the required sense, at all ([5.29], 1–243ff.).

VI THE UNITY OF SCIENCE

Another common feature that the new empiricism shared with the old was its 'reductionism'. Locke, for example, had insisted that the various kinds and aspects of knowledge could all be reduced to a single type and source, namely the 'sensations' with which our sense organs furnish us in 'experience' ([5.78], 2.1.24). In the case of the new empiricism a similar but linguistic reductionism led to a grandiose project known as the *International Encyclopedia of Unified Science*. In this work it was hoped to show that all the different sciences, including the physical, biological and human sciences, could be expressed in a fundamental common vocabulary. Carnap's proposal for this purpose was what he called the 'thing-language'—that which we use 'in speaking about properties of the observable (inorganic) things surrounding us': such words as 'hot', 'cold', 'heavy', 'light', 'red', 'small', 'thick' etc. (It will be noticed that this proposal, unlike the verification principle, is about words rather than statements.)

One aspect of the 'unity of science' that is of particular interest is its application to human beings. It was thought that descriptions of human feelings, for example, could be reduced to statements about observed behaviour ('behaviourism'), or other physical occurrences such as those in the brain. (Here we see the beginnings of the 'physicalism' which, in various forms, is prominent in the philosophical literature of today.) The difficulties of behaviourism can be brought out by their effect on Wittgenstein in his 1930–33 lectures as recorded by G.E. Moore. 'When we say "He has toothache"', asked Wittgenstein, 'is it correct to say that his toothache is only his behaviour, whereas when I talk about my toothache I am not talking about my behaviour?' This cannot be so, because 'when we pity a man for having toothache, we are not pitying him for putting his hand to his cheek'. Again, 'is another person's toothache "toothache" in the same sense as mine?'. He now saw that according to the verification principle, the meanings, following the difference in methods of verification, must indeed be utterly different. Indeed, the difference was not merely *between* methods of verification, since there is no verification at all in case of the first person: 'there is no such thing as verification for "I

have", since the question "How do you know you have toothache?" is nonsensical' ([5.16], 307).

Carnap tried to accommodate such difficulties in a number of writings. In one of these he admitted that a person N_1, 'can confirm more directly than N_2 a sentence concerning N_1's feelings, thoughts etc.'; but, he went on, 'we now believe, on the basis of physicalism, that the difference…is only a matter of degree' ([5.10], 79).

VII THE 'ELIMINATION OF METAPHYSICS'

One of the main objectives of logical empiricism was to provide a way of demarcating the meaningful statements of science and ordinary life from the 'pseudo-statements' of metaphysics. Now the word 'metaphysics' may mean various things. The verificationists used such examples as Heidegger's statement 'The nothing nothings', and F.H. Bradley's talk about 'the Absolute', as in the statement: 'The Absolute enters into, but is itself incapable of, evolution and progress'. This, said Ayer, was 'a remark [he had] taken at random' from Bradley's *Apperance and Reality*. It was, he claimed, 'not even in principle verifiable', and therefore nothing more than a 'metaphysical pseudo-proposition' ([5.1], 49).

Now such a sentence, plucked 'at random' out of its context, might well strike the reader as meaningless. But is this so because it is unverifiable? Perhaps, if we read Bradley's argument, we would find there the means of assessing the truth of his statement. *That* would be the appropriate method of verification in this case. In taking the statement out of its context, Ayer had merely denied us access to the relevant method of verification.

Perhaps what Ayer had in mind was that the method of verification would not be *empirical*. Now this might well be true; but what would it show? It might show that the statement itself is not empirical; but perhaps it was never intended to be so. Merely to classify it as non-empirical is not to show that it is a 'pseudo-proposition', nor even that it is unverifiable.

Another class of statements to which verificationists turned their attention were those about God. Such statements, it was argued, were not necessarily meaningless, but the meaning ascribed to them should not exceed their verificatory content. Carnap spoke of an early phase of the concept of God, in which He was conceived as a corporeal being dwelling, say, on Mount Olympus. Such statements would satisfy the verificationist criterion, but this would not be true of the metaphysical accretions of later phases of the concept. Ayer put the matter thus:

> If the sentence 'God exists' entails no more than that certain types of phenomena occur in certain sequences, then to assert the existence of a god will be simply equivalent to asserting that there is the requisite regularity in nature.
>
> ([5.1], 152)

Here again the requirement is that of sense experience, of the observation of phenomena by means of the senses. But is this the only kind of experience? In a further passage Ayer spoke of 'mystical intuition'. He would not, he said, deny that 'the mystic might be able to discover truths by his own special methods'. But, he went on, the mystic's statements, like others, 'must be subject to the test of actual experience'. But is not the mystic's experience itself a kind of 'actual experience'? Some further argument would be needed to show that such experiences cannot count as verificatory.

This difficulty is part of a fundamental problem about the whole empiricist programme. How is their preference for empirical statements, and empirical methods of verification, itself to be justified? John Locke, the father of empiricism, posed the question: 'Whence has [the mind] all the materials of reason and knowledge?', to which he replied: '… in one word, from *experience:* in that, all our knowledge is founded; and from that it ultimately derives itself ([5.78], 2.1.2). But if this were so, how could this knowledge itself have been obtained? The claim that all knowledge comes from experience cannot itself be derived from experience.

A similar difficulty arises if we turn the verification principle or the criterion of verifiability on themselves. They are not themselves empirical statements: must they not suffer the same fate as other non-empirical statements? As Bradley observed, 'the man who is ready to prove that metaphysics is wholly impossible…is a brother metaphysician with a rival theory of first principles' ([5.77], 1).

This difficulty was recognized by verificationists, who made various proposals to overcome it. Schlick claimed that the verification principle was 'nothing but a simple statement of the way in which meaning is *actually* assigned to propositions, both in everyday life and science' (5.24], 458–9); while Ayer said that his criterion of verifiability was to be regarded 'not as an empirical hypothesis, but as a definition' [5.1], 21). But what reason would there be for accepting this definition or Schlick's claim? As we have seen, they are not confirmed by the various ways in which the word 'meaning' is actually used.

Another idea was to describe the principle or the criterion as a 'proposal' or 'methodological principle'. This would exempt them from self-application, since a proposal cannot be described as true or false, verified or unverified. But what would it mean to adopt the proposal in

question? According to it, I am to describe certain statements as meaningless. But how can I do that unless I *believe* them to be meaningless? (Of course I could *say the word* 'meaningless', but that is a different matter.)

Leaving this difficulty aside, we may ask what would be gained if such a proposal were to be adopted. One of the motives behind it, as we have seen, was that of reductionism and the 'unity of science'. It was thought, and hoped, that the multifarious jungle of human discourse could all be reduced to a single type. Wittgenstein, in his later writings, spoke disparagingly of such aspirations as due to a 'craving for generality'. He now maintained that the uses of language—'language-games', as he called them—are irreducibly various, and that the philosopher's task was to notice and expound the differences, resisting any temptation to impose an artificial uniformity.

VIII THE ACCOMMODATION OF ETHICS

How are ethical statements to be accommodated under verificationist criteria? Should they be accommodated at all? Carnap, at one stage, declared: 'we assign them to the realm of metaphysics'. But while it might be thought that metaphysical discourse can safely be set aside as unnecessary for the conduct of human life, this could hardly be so in the case of moral discourse. Could the latter be regarded, perhaps, as a kind of empirical discourse?

According to Schlick, this was the proper way of regarding it, as is clear from the first sentence of his book on the subject: 'If there are ethical questions which have meaning, and are therefore capable of being answered, then ethics is a science' ([5.22]). He went on to maintain that all of these conditions are fulfilled in the case of ethics. Words such as 'good', he claimed, are used to express desires; and these belong to the science of psychology. The 'proper task of ethics' was to examine the causal processes, social and psychological, which would explain why people have the desires they have.

But cannot something be described as morally good or desirable even if people do not desire it? According to Schlick, this would make no sense. 'If… I assert that a thing is desirable simply in itself, I cannot say what I mean by this statement; it is not verifiable and is therefore meaningless' ([5.22], 19). There is no place in Schlick's account for the aspect of morality on which Kant laid so much emphasis: the conflict between desire and duty, which is such a familiar aspect of moral life. He rejected Kant's account of moral discourse, accusing him of being out of step with the ordinary meaning of 'I ought' (Ibid., no). Yet it makes good sense for a

person to say, for example, that he ought to do X because he promised, even though it is contrary to his desire.

A more common approach among logical empiricists towards moral statements was to deny that they are really statements. In a paper published in 1949, Ayer referred to his earlier view, 'which I still wish to hold, that what are called ethical statements are not really statements at all, that they are not descriptive of anything, that they cannot be either true or false'. This view, he now admitted, 'is in an obvious sense incorrect', since in ordinary English 'it is by no means improper' to speak of ethical statements as statements or descriptions, or to describe these as true or false. Nevertheless, he continued, 'when one considers how these ethical statements are actually used, it may be found that they function…very differently from other statements'. Yet, after all, 'if someone still wishes to say [they] are statements of fact, only it is a queer sort of fact, he is welcome to do so' ([5.3], 231–3). Here again is the craving for uniformity—a wish to deny that ethical facts are facts, because they do not conform to a preferred model.

To support his denial Ayer resorted to the existence of moral disagreement. 'Let us assume that two observers agree about all the circumstances of [a] case…, but that they disagree in their evaluation of it.' In that case, he claimed, 'neither of them is contradicting himself (Ibid., 236). Now in such a case we might indeed conclude that there is 'no fact of the matter'. But there are many other cases in which this is not so. If I have said I will do you a favour, then I *would* be contradicting myself if I denied responsibility for doing what I said. In that case it would be true, and a fact, that I am under an obligation to do what I said. And, as Ayer recognized, the word 'true' is freely used in moral discourse, in various contexts.

As we have seen, Schlick regarded moral statements as factual and verifiable, while Carnap and Ayer tried to dispose of them in other ways. Another writer tried to analyse them into factual and non-factual components. This was the moral philosopher C.L.Stevenson, whose works were cited with approval by logical empiricists. According to the first of Stevenson's 'working models', the statement 'This is wrong' means 'I disapprove of this; do so as well'. (He dealt similarly with the words 'ought' and 'good'.) The first part of this, he pointed out, is amenable to verification, while the second, being an imperative, is not ([5.25], 21, 26).

A difficulty with which Stevenson wrestled was about applying this account to someone who is *asking* himself whether X is wrong. This would not be a factual psychological question, about whether he does in fact approve of X; the question for him would be whether he *ought* to approve of it. Another difficulty is that of making sense of the imperative 'do so as well'. A person can be requested to do something only if he can choose to

do it; but this is not the case with approval. If you give me suitable reasons, I may *come to see* that X is wrong; but I cannot do so at will, in response to an imperative.

The connection with reasons was, however, denied by Stevenson. He admitted that 'a man's willingness to say that X is good, and hence to express his approval, will depend partly on his beliefs', but pointed out that 'his reasons do not "entail" his expression of approval' ([5.26], 67). Now this is true enough; indeed, it is not clear in what sense an expression can be 'entailed'. But it remains the case that on the basis of suitable reasons I may come to see (recognize, know it to be a fact) that X is wrong and ought not to be done. If such facts do not conform to the reductionist programme of logical empiricism, then it may be the programme that should be questioned, rather than the status of moral facts.

CHAPTER 6

The philosophy of physics

Rom Harré

WHAT ARE THE BRANCHES OF THE PHILOSOPHY OF PHYSICS?

One convenient way of dividing up the investigations that make up the philosophy of physics could be the following:

1 Analytical and historical studies of the development and structure of the leading concepts used in the science of physics, such as 'space-time', 'simultaneity' and 'charge'.
2 Naturalistic and formal studies of the methodologies that have been characteristic of physical science, including experimentation and theory-construction, assessment and change.
3 Studies of the foundational principles of significant examples of physical theory.

These three sorts of investigations can be found throughout the long history of philosophical reflection on the nature of physical science. For instance, in the writings of Aristotle [6.2] (*c.* 385 BC) there are extensive discussions of many of the questions that still concern philosophers of physics about the nature of the properties of matter. Conflicting views about the methodology of physics are easily identified in the writings of the ancients. For example, Plato's remark that the task of astronomers is to 'save the appearances' has been contested, interpreted and reinterpreted. In Lucretius' *De rerum natura* [6.31] there is a sketch of a metaphysical foundation for a general physics supposedly applicable everywhere in the universe based on the idea of a world of unobservable material atoms.

It seems that these three clusters of studies could also be found in the philosophy of chemistry. To disentangle what it is that is characteristic of studies in the philosophy of physics, I shall have to say something about

what distinguishes physics from all other natural sciences. Nowadays, one would be reluctant to try to draw a hard-and-fast line between physics and the other sciences. But for the purposes of this article, a rough division might be effected as follows. Physics is the study of the most general properties of matter. In chemistry and biology the unique properties of particular kinds of matter are examined. With this rather vague prescription in mind, we can pick out as physics studies of such ubiquitous features of the material universe as its spatio-temporal structure, and of the common properties that every material being shares with every other, such as mass-energy and mobility. This way of distinguishing subject by scope is rather simplistic. It is only very recently that matter and radiation have been found to be mutually convertible and so to have common properties. But the study of optics and the study of mechanics have always been or almost always been branches of physics.

It is worth emphasizing the antiquity of philosophical investigations of the science of physics. It has never been free of some philosophical content. In times of crisis questions about ontology and about method come to the surface. By a time of crisis, I mean a moment in the history of the investigation of the physical universe in which the best theories that we can construct according to the local criteria for identifying a good theory, are in apparently irresolvable conflict with one another while they are indistinguishable by reference to the results of observation and experiment. In these circumstances, philosophical speculation returns to the centre of the stage. Physics, more dramatically than any other science, develops through the interplay between philosophical analysis of conceptual foundations and what, at first sight, seems to be an independent scientific research programme. I shall illustrate this feature of the history of physics from time to time in the course of making my more detailed remarks.

Before I turn to sketching some particular examples of conceptual analysis, there is one further general distinction to be borne in mind. Since the days of Euclid's formalization of the science of geometry, mathematics has played a central role in the development of physics, but this role has not been uncontroversial. There is an important distinction between different ways of interpreting mathematical formalisms [6.47]. Is the abstract mathematical representation of the laws of physics auxiliary or representational? Auxiliary mathematics consists of formal devices by which the knowledge of the physicist can be conveniently summarized and manipulated. I owe to John Roche a very simple example of auxiliary mathematics. This is the grid of lines of lattitude and longitude which geophysicists have laid over the earth. A more complex example is the system of deferent circles and epicycles with which Ptolemy calculated the ephemerides, the risings and settings of the heavenly bodies. We are not justified in assuming a priori that all

the technical devices employed in some mathematical formulation of a law or theory have physical counterparts. The laws and principles of quantum mechanics can be expressed mathematically in terms of vectors in Hilbert space. But what could the physical meaning of the leading concepts of the Hilbert space representation possibly be? What physical sense could one give to the idea of a vector rotating in an infinite dimensional 'space'? Equally, it is a misunderstanding of the second Bohr theory of the atom to ask for the physical counterparts of the charged oscillators which replaced the planetary electrons of the earlier theory. On the other hand there are plenty of theories in physics, such as the Clausius-Maxwell theory of the behaviour of gases in which every element in the mathematical representation is taken to be the counterpart of some determinate feature of the physical system. Each variable in pv=⅓ nmc^2 can be given a physical meaning in terms of the molecular model of gas.

I shall illustrate the three branches of the philosophy of physics by outlining some recent discussion of topics of perennial interest. To illustrate analytical and historical studies, I shall draw on problems of the interpretation of relativity theory. An alternative example could have been the concept of 'mass' which has also had a long and interesting development. It has been sharpened, subdivided and differentiated in response to experimental and theoretical advances ([6.28]). To illustrate methodological studies I shall take some very recent work on the role of experiments in physics ([6.20]). I shall also outline the debates between realists and anti-realists, concerning the interpretation and role of theories in physics. Do they describe unobservable but real entities and processes or are they merely devices for predicting more phenomena ([6.46])? If the former, how could we ever know whether we are getting a better and better picture of the hidden world of.causal processes if we can never observe it directly ([6.33], [6.12], [6.3])? To illustrate foundational questions I shall turn from the development of the dispositional treatment of the foundations of Newtonian matter theory to debates about the meaning of the leading concepts of quantum field theories ([6.10]). An alternative example could have been the discussions of the significance of the Bell inequality and the status of the EPR experiment ([6.16], [6.6], [6.5], [6.4]).

THE ANALYTIC AND HISTORICAL STUDIES OF CONCEPTS

I shall divide the topics that fall under this heading into two broad groups. There are those which are concerned with the analysis of concepts which at first sight are taken to be independent of the

particular theories within which they fall. So there are analyses of space, time, causality, property, etc., which, though influenced by particular theories in physics seem to be in some respects, independent of them. On the other hand, there are analyses of leading concepts such as mass, momentum, charge, force, etc., which it is hard to imagine being carried out independently of the particular theories in which they have, from time to time, been embedded.

These analyses, whether generic or specific, are usually conducted with respect to larger questions. So, for example, developing and arguing for analyses of concepts such as space and time, are part of long-running controversies between absolutists and relationists. Do the concepts of 'absolute space' and 'absolute time' make sense? Some relationists would argue that these hybrid concepts are logically incoherent. Discussions about the proper interpretation of the concepts of mass, charge, force and so on, are related to the broad issue of whether the physical properties of things are best understood as dispositions, powers and propensities ([6.23], [6.43]). I shall take up this question again in the foundations section.

In investigating the status of the kinds of concepts that I have mentioned, it is important to bear in mind that these analyses are relative to the state of physical science at the time that they are being carried out. Yet they bear upon such general questions as whether we should favour an absolutist or a relationist theory of space and time, or whether all physical properties are really dispositions. Debates such as that between Leibniz and Clarke ([6.1]) over the nature of space and time, though set in the context of Newtonian physics, nevertheless have universal significance.

One cannot say that there is no philosophy of physics independent of the state of physical theory. The generality of the concepts involved sometimes allows us to investigate concepts and to develop arguments which transcend particular epochs in the history of the science itself.

At the beginning of this century relativity theory seemed to present a radical challenge to a well-established conceptual system for expressing spatial, temporal and causal relations. The community of physicists had become accustomed to the idea of an absolute frame of reference, though it was hardly ever necessary to invoke it in solving any actual problem in physics. According to the popular myth, relativity theory was something extraordinary and utterly radical. I hope to show that such a picture is far from an adequate portrayal of the way in which theories of space, time and space-time had evolved in the course of the development of post-Aristotelian physics. Among many deep questions that can be asked with respect to space and time is whether there is a relation between the spatial and temporal location of an experimenter or observer and the forms that experimenters or observers would use to

express the laws of nature. Are they or are they not the same when an experimental apparatus is run at one place and time rather than another? Would the laws of nature seem to be the same if studied on a moving platform as on one which was stationary relative to some apparently fixed frame of reference? Or on one which was accelerating with respect to some other platform on which stood the apparatus with which the experiments had previously been done? Ultimately the deepest question would be—could we discover which system of bodies was moving or accelerating and which was *really* stationary by looking for indicative changes in the laws of nature?

There are two ways in which absolutist views on space and time have been challenged. Relativity theory challenges the idea that there is a privileged reference frame, absolutely at rest, to which all motions uniform or accelerating could be referred. There is also the 'relationist' challenge to that idea which can be mounted independently of the question about reference frames. Relationists believe, with Leibniz, that space and time do not exist independently of the material system of the world. They are among the relational properties of that system. Absolutists (lately called 'substantivalists' to distinguish them from those who favour ultimately a non-relativist position in physics) believe that the space-time manifold is a substance which exists independently of the material world of charges, forces and fields ([6.11]). My illustrative example concerns the absolutist/relativist issue, not the substantivalist/relationist debate.

Let me briefly sketch how one now sees the historical progression that leads to the contemporary interpretation of relativity theory. The idea that the forms of laws of nature are independent of spatio-temporal location is expressed in the technical notion of covariance of the law under a coordinate transformation. To take a simple example: changing the coordinates of a location in a Cartesian plane each by a fixed quantity is a transformation. If the coordinates were x and y before the transformation and are x-a and y-b after, it is as if we moved the whole reference frame a units to the right and b units upwards. If a law of physics has the same form before and after the transformation is applied to the coordinates, we say that it is 'covariant under the transformation'. However, that technical idea is a version of a more fundamental conception. It expresses the idea that the forms of the laws of nature are indifferent to (that is unaffected by) changes in location, epoch or relative velocity of the frame with respect to which they are studied. We can detect the very beginnings of the covariance or indifference to location idea in the writings of Nicholas of Cusa ([6.4]). Contrary to the Aristotelians, who believed that space and time had instrinsic structures, the laws of nature differing with the location in which they are studied within that structure, Cusa introduced a general principle of

indifference. His elegant epigram ran as follows: 'the centre and the circumference of the universe are the same', or in other words, physical laws are indifferent to their location in space and also, he believed, in time.

The next step in freeing physical processes from the influence of space and time came with the work of Galileo ([6.18]). In a striking image, he asked us to imagine conducting experiments inside a ship on a smooth sea. He argued that it would be impossible to discover whether the ship was in motion or at rest relative to the sea, by experimenting in a closed cabin. The relative motion between ship and ocean would have no effect upon the results of our experiments. Physics would always be the same inside the ship, no matter what its uniform velocity was relative to the ocean. This is the principle of Galilean relativity. Newton certainly subscribed to this principle. The laws of mechanics were thought to be indifferent, or covariant, as we might say to the Galilean coordinate transformation. In that transformation we can change the mathematical expression for uniform motions by any amount we like, the mathematical equivalent of slowing down or speeding up the ship by a definite amount relative to the ocean, and the laws of nature will preserve their form when expressed in the new coordinates.

All went merrily until the development of a comprehensive set of laws for electromagnetism by Clark Maxwell. Voigt showed in 1891 that Maxwell's laws were not covariant under the Galilean transformation. This implied that it might be possible to find electromagnetic evidence of our real or absolute motion through some uniform and universal background. It seemed that, in principle, one could find one's way about and perhaps even determine one's velocity with respect to some absolute frame of reference. Since it was the electromagnetic laws which were not covariant under the Galilean transformation, perhaps an electromagnetic aether might serve as just the absolute background that physicists needed. This was the project of Michelson and Morley (for an exposition of the work of Michelson and Morley, emphasizing the importance of the apparatus see [6.22]).

By the end of the nineteenth century, however, it had become clear that there was a coordinate transformation under which the laws of electromagnetism were covariant. This was the Lorentz transformation. The situation had now become very interesting. The Maxwell laws of electromagnetism are covariant with respect to the tranformation of Lorentz but not with respect to that of Galileo. The laws of mechanics are covariant with respect to the transformation of Galileo but not with respect to that of Lorentz. Both are covariant with respect to the Cusan

transformation, but this was taken to be so obvious as not to be worth remarking. This was the situation that Einstein confronted.

Essentially, Einstein had to solve two problems ([6.15]). How to make a reasoned choice between electromagnetism on the one hand and mechanics on the other as the most basic physical science. His reasons for choosing the electromagnetic option have to do with the need he felt to preserve a thorough-going symmetry between the process of electromagnetic induction that occurs when a moving conductor cuts the lines of force of a stationary magnetic field and that which occurs when a moving magnetic field interacts with a stationary conductor. If we assume an electromagnetic aether, the processes will be different in each case. He thought this intolerable. So he chose to privilege electromagnetism by denying the necessity to postulate an aether. This choice served not only to eliminate the aether from physics but to elevate the Lorentz transformation to be the dominant principle of covariance. His second problem was to find a new form for the laws of mechanics so that they too would be covariant under the Lorentz transformation. If this could be done, physics would be unified. There would be one physics and all its laws would be independent of the place, moment and relative velocity of the material system in which they were tested. He found these laws and they are none other than the laws of the special theory of relativity.

But now we can see that there was a third problem. With respect to what spatio-temporal structure are the new laws of mechanics, together with the laws of electromagnetism, indifferent? Einstein did not solve this problem himself. We owe its solution to Minkowsky ([6.36]). In the Minkowsky manifold, space and time are not independent systems of locations and moments. There is a four-dimensional manifold in which physical processes are imagined to take place. Minkowsky coordinate systems, moving with uniform relative velocity with respect to one another, now become the frames of reference with respect to changes between which the laws of nature must be indifferent. Wherever and whenever an experiment is conducted in the Minkowsky manifold, the result should be the same.

General relativity simply extended the same idea one step further. Einstein pursued the project of finding a formulation for the laws of nature which would leave them covariant under the general coordinate transformation, including that between frames of reference accelerating with respect to one another. Corresponding to the Minkowski manifold of special relativity came the famous curved space of general relativity which represents a manifold, with respect to which the laws of nature are absolutely indifferent.

The story of relativity is the story of one programme progressively developed, acquiring a more and more sophisticated form as the history

of physics has unfolded. It begins in 1440 with Cusa's *Of Learned Ignorance* ([6.41]) and culminates in general relativity. At each step yet another candidate for the one absolute space-time manifold was deleted from physics.

There is a connection with the absolutist (substantivalist)/relationist debate. Clearly, if the laws of nature are indifferent to their presumed locations in manifolds of space or time or space-time, then those manifolds can play no role whatever in the physical sciences. Absolute space, absolute time and absolute space-time are redundant. Experimental proof of this redundancy by Michelson-Morley is not in fact part of the history of relativity theory. It was, so to say, a comforting result that confirmed Einstein in the wisdom of privileging electromagnetic laws and their properties in his programme of research.

Relativity has turned out to be a cousin of relationism. But the triumph of relationism is by no means the foregone conclusion. There are still some reasons for thinking that there may yet be a place for an absolutist space-time in the physical sciences. These have to do with the status of the space-time manifold as required by general relativity. It is argued ([6.38]) that even in the absence of all matter-fields this manifold would still have a structure. Therefore, it cannot be just one of the sets of relations that order the material stuff of the world.

Exemplary cases of conceptual analysis of other physical notions have occurred throughout the history of physics. One notices in the Clarke-Leibniz controversy, as a footnote, a conceptual investigation into the notion of quantity of motion, in which the distinction between momentum and energy is foreshadowed.

METHODOLOGICAL PROBLEMS IN THE SCIENCE OF PHYSICS

From the earliest days of mathematical astronomy, the nature of physical theory has been a matter of perennial dispute. The arguments have turned on the balance that one can draw between epistemology and ontology. Clearly, in some sense, that which is known through perception, the observable, has some kind of privileged ontological status, even though we know that many of our ontological claims made on the basis of perception are disputable and have sometimes had to be revised. Physical theory, however, characteristically seems to refer to processes such as the orbiting of the planets, entities, such as subatomic particles and structures, such as the curvature of space-time, that lie beyond perception. What, then, is the status of our knowledge of these beings and what of their standing as existences alongside and perhaps as components of that which we can perceive? Anti-realists have tended

to privilege the deliverances of the senses, particularly the sense of sight, both ontologically and epistemologically. Realists, more cautious epistemologically, have nevertheless been bolder ontologically, and have tried to find ways in which attributes of physical theories, particularly their power to engender new kinds of experiments, have been taken as grounds for interpreting them realistically, and thereby adding to our ontology, enlarging the list of kinds of things we believe to make up the world. However, sceptics have little difficulty in finding grounds for pressing the interpretation of physics back in the anti-realist direction. They ask how we can be sure of the truth of our laws, when we have very limited grounds for accepting them, the classical problem of induction. How we can be satisfied with theories when our grounds for accepting them are only their predictive and retrodictive powers, since it is easy to demonstrate that there are infinitely many theories with the same predictive and retrodictive power, the problem of under determination, first formulated by Christopher Clavius. Quite recently a new mood has spread among philosophers of physics. Diagnosing the source of the weakness of realism as a commitment to the principle that science aims to establish the truth of the propositions of physical theory, a new school of neo-pragmatist philosophies of science animated to some extent by a reading of the philosophy of Niels Bohr ([6.27], [6.37]) has appeared. These philosophers have argued that a realist interpretation of physical theory should be taken as doctrine that theories are good in so far as they give us just sufficient understanding of the unobservable to allow us to manipulate it ([6.21]). Manipulability is the concept which allows us to penetrate beyond the bounds of perceptibility.

There are some important consequences that flow from the new 'pragmatic' realism. In one respect it harks back to an eighteenth century conception of the logical status of physical properties. At that time, the popular philosophy of physics decreed that our knowledge of the physical world was a knowledge of the powers and disposition of otherwise unknown entities. We knew them through what they could bring about. In very much the same way, the Bohrian philosophy of physics asks us to consider the world in so far as it appears to us through the dispositions it displays in apparatus of our own devising. There is another consequence which follows from this point of view. The early ecologists developing concepts to understand the way in which species of animals are related to their physical environment have coined the concept of *umwelt*. The *umwelt* of a species is that region of the world which is available to the species by virtue of its biological endowments. The physical world is broader and richer than the sum of the *umwelten* of the animals which inhabit it. This concept was used to explain how it was possible for different species of animals

to occupy the same physical environment. Each carved out its own *umwelt*. In a similar way, one could treat the worlds of physics as *umwelten* and the development of the physical ontology as the successive marking-out of an ever-changing *umwelt* for humankind with respect to the experimental apparatus and conceptual systems with which they explored it. So the new philosophy of science is realist in a new way. The world is that which we make available to ourselves and our knowledge of it is our knowledge of what it is capable of doing and being made to do by our manipulations.

The next question that obviously arises in relation to the move from anti-realist to realist conception of physical science concerns the nature of physical theory. If we think of physics in the anti-realism manner as the statistics of perceptual experiences or even the statistics of the performance of instruments, while all else is of no ontological significance and merely serves the role of intervening variables to carry us from one empirical statement to another, we would be inclined to follow the philosophies of science of Mach ([6.32]) and Duhem ([6.14]). According to these philosophers theory performs only a logical role: an inference machine for Mach, a taxonomical system for Duhem. However, when one examines physical theory and considers the development of the theorizing in a certain field of enquiry, one is struck by the fact that the theories of physics do not seem to be about the world at all. They are at least, ostensibly, about models of the world. A model, in this sense, can be either an abstract representation (a homeomorph) or a paramorph, which is an analogue of something we do not yet know but believe to exist. A law of nature like pv=a constant, is an idealised description of the behaviour of an abstract version of a real gas. The corresponding theoretical proposition, $pv={}^1/_3\, mc^2$, is a description of the molecular model of what a gas might be like. This view of theory has been about for more than three decades ([6.48], [6.26]). It is now becoming popular again. A philosophical question that is immediately evident if we think about theory in this way, is how this view fits with realism. Thinking it through, the fit is rather nice. Having given up the idea that realism must be defined in terms of the truth of propositions but rather thought out with reference to the manipulability of objects to which theory guides us, the idea of theory centred on a model of reality is very attractive. Model and reality are, so to say, beings of the same sort, and we can consider the fit of a model to that of which it is a model in terms of similarities and differences. The problem of which similarities are to be counted as important is itself readily soluble by reference to the structure of the theoretical concepts which constitute the discursive part of the theory. Some properties will appear as essential and some as accidental. Similarities and differences gain their importance from the extent to which they are drawn from the real and nominal essences of the beings in question, that is from our ideas about their inner

constitutions and from our criteria for assigning them to kinds on the basis of their observable properties.

The shift from positivism to realism to what one might call post-realism or neo-pragmatism also involves rethinking of the role of experiments. In the logistic account of science, whether positivistically conceived or developed in the fallibilist mode by Karl Popper ([6.42]), gives a logical account of experiment. An experiment is done in order to provide a rational being with a proposition of the form 'Some A are B' or alternatively, if it so turned out, 'Some A are not B'. The significance of the experiment is determined by logical relations between those propositions which describe the experimental results and the general hypotheses to which they are considered relevant. So the logical account requires us to accept either inductivism or fallibilism. In the former we would have to accept the force of some pattern of inductive reasoning, in which the result in some cases, those that have been studied, are generalized to all cases, a notoriously shaky inference. In the latter we would have to rely upon the fallibilist pattern, that while we can draw no certain conclusion from a positive result, a prediction that turns out to be false justifies us in rejecting the hypothesis from which it was drawn. Neither is satisfactory.

The evident mismatch between the logicist way of construing experiments with the neo-pragmatist view of science, suggests the possibility of conceiving of experimentation in a much broader fashion. If we are endeavouring to see by experiment how well our models match reality, then we should not think of experimenting as a way of producing propositions to stand in a logical relation to a theory. We should think of the performance of an experiment as doing work in the world directed towards producing a certain outcome under the guidance of the theory. The question is not whether the theory in use is true or false, but whether, read as a set of instructions, it enables us to do what we aim to do. There is a sense to be given to the verisimilitude of a theory, but not in the prepositional mode, not centred on truth. In particular we are concerned with manipulating the world as if it were well-matched to our model. Indeed, there are specific model-matching experiments, some of which have been of enormous importance in the development of science. One which I find particularly instructive is the Page and Townsend experiments, by which a model of the flow of fluids with respect to bounded media is matched against a subtle experimental revelation of what the structure of such fluid motion 'actually' is (that is what the motion appears to be by the use of an ultramicrosope). Interesting cases arise where our faith in the iconicity of our models is based only upon their power to suggest manipulations. It seems to me that our main reason for believing in the reality of the magnetic field is the set of effects we can bring about by

procedures which, we believe, act directly on that field. Changes so induced then bring about effects we can observe, such as the swing of the pointer of a galvanometer.

The notion of 'model' which I have been assuming in this discussion so far is the familiar one of analogue. One system is a model of another if it is analogous in relevant ways. But there is another, connected, sense of 'model' which has also been prominent in the writings of some philosophers of science ([6.49], [6.50]). In logic a model is a set of entities and relations which can be used to interpret an abstract calculus. If the formulae of the calculus, interpreted as meaningful sentences by the use of such a domain of entities and relations, are all true when used of that domain, then that set of entities and relations is a model for the calculus. In logic there is a calculus and a model is needed to give it meaning; in physics a model or analogue of reality is imagined and a theory is subsequently created by describing the model. At the end of the day, so to say, the relation between calculus, theory and model is the same in both cases. However, in the order of creation, logic and physics run in opposite directions.

Disputes about how physical theory should be presented can be found throughout the history of physics. They were particularly prominent in the sixteenth century when many philosophers treated the heliocentric and geocentric astronomies, many versions of which were on offer in the mid-sixteenth century, as alternative mathematical systems. Ways of answering the question as to which formal system was to be preferred were interestingly divided between those who thought that anti-realist criteria, like simplicity and logical coherence, were of prime importance and those who favoured realist criteria, like the ontological plausibility of the model of the solar system that the mathematical structure represented.

In the late eighteenth, through the nineteenth century, Newtonian mechanics became the focus of a considerable effort to rework its formal representation. This was in part animated by the discovery of Maclaurin's paradox, perhaps more justly attributed to Boscovich. Boscovich [6.8] noticed that the grand Newtonian theory was internally incoherent, indeed, self-contradictory. The concept of action, 'force × time', which was essential to setting up Newton's third law, that in action by contact action and reaction are equal and opposite, required all such action to take place in a finite time. But the Newtonian ontology required the ultimate material particles to be truly hard, that is incompressible. It follows that all action by contact must be instantaneous, since the ultimate contacting surfaces cannot deform. Forces in instantaneous Newtonian impact would, according to the mechanical definition of action, be infinite. But there is no place for infinite forces in the Newtonian scheme. A variety of strategems were

developed to try to resolve the difficulty. In general physicists in France tended to favour theories without forces ([6.13]), whereas the English and some of their continental allies tended to favour a mechanics without matter, the so-called dynamical interpretation ([6.24]).

Great advances were made in the mathematics of physics, in the course of the working out of these alternatives. The Lagrangian formulation, the Hamiltonian formulation and Hertz's immensely influential reformulation of mechanics were all attempts in one way or another to come to terms with the same fundamental problem.

But there is another kind of investigation which we could classify as foundations of physics. This is the project of finding the minimal or most elegant formal representation of a scientific theory. In these cases, the mathematician-philosopher is driven by an interest in the aesthetics of formalisation rather than by some metaphysical paradox, such as the one uncovered by Boscovich and Maclaurin. In the present century some very interesting developments have hinged on attempts to provide alternative formal representations in which the very foundations of a theory are revealed in a clear and unambiguous way. For example, the matrix theory of Heisenberg and the wave mechanical formulation by Schrödinger of the laws of quantum mechanics, though they were shown to be mathematically equivalent in some sense, were animated, in part at least, by ontological differences between their authors. Lucas and Hodgson [6.30] sum up an enormous variety of ways of arriving at the Lorentz transformation. There are many different paths by which this important group can be arrived at. Sometimes exercises of this sort, the formulation of an alternative mathematical representation, are significant. But sometimes they seem to be little more than formal exercises, mere auxiliary mathematics.

The way that the results of experimenal manipulations enter into the record of physics as *phenomena* is exceedingly complicated. Goodings [6.20] has analysed the paths by which the personal experience of the discoverer of a new phenomenon makes it available, conceptually and manipulatively to the community of scientists and ultimately to everyone. A key move in the transformation of personal experience into public phenomenon is the elimination of all traces of the human hand that was involved in the early occasions of its production. Goodings shows that the circularity of the motion Faraday demonstrated as a natural electromagnetic effect was extremely difficult to produce on the laboratory bench, let alone understand. To explain how this transformation is achieved Goodings introduces the idea of a 'construal'. It could be a way of describing, a picture, a diagram or anything by which a scientist, in interaction with others, makes the phenomenon available as such. In applying construals the great scientists of history transform complex chains of fragile steps

into simple sequences of surefire manipulations. Faraday describes seventy-five steps in recording how he first produced circular electromagnetic motion in his own laboratory. The published description of the procedure mentions only forty-five steps. The final simplification to a mere twenty steps occurs in his set of instructions for anyone to reproduce the effect.

FOUNDATIONAL DEBATES

The indeterminacy of subatomic processes that had first appeared in experiments with electrons was eventually canonized rather than resolved in the mathematical theory of quantum mechanics. Quantum mechanics has been the source of one of the major conceptual problems which has beset physical science for the last seventy years. At the heart of Newtonian physics was an assumption of the strict causality of all physical processes and the determinate character of all physical effects. Quantum mechanics provides a formalism by means of which a description of the state of preparation of a system can be linked to predictions about the probabilistic distribution of the effects of certain treatments of that system. The theory provides no way in which determinate outcomes can be predicted from knowledge of the original state of the system. Here is the dilemma. Is this because the way we now understand the state of any physical system is actually complete? This would seem to imply that there are real propensities to vary the outcomes of identical operations performed on identically prepared systems, contrary to the ordinary notion of determinate causality. Or is there something missing in our knowledge of electrons and other subatomic particles, knowledge which would restore the determinate structure of physical theory? Perhaps there are 'hidden variables' which do behave deterministically.

Arguments about the viability of hidden variable theories are almost as old as quantum mechanics itself. Can we find a theory based on the assumption of the existence of a set of attributes which we can ascribe to subatomic particles and their states of preparation from the determinate mathematics of which we could recover the probabilistic results for quantum theory as it is now understood?

So far, the answer has been equivocal. It is now clearly understood that there is no way in which a theory employing the familiar classical concepts of momentum, energy and so on, could be formulated, to provide a determinate hidden variable theory ([6.5]). Every experiment so far conducted has only given stronger and stronger support to the 'Bell inequality', the mathematical condition that expresses the principle of no hidden variables. On the other hand, there have been hidden variable

theories constructed using exotic concepts from which the existing quantum mechanical results can be recovered [6.44]. However, they lack any serious degree of physical plausibility.

In quantum field theory, another and yet more fascinating conceptual problem has arisen. It is now some fifty years since the idea of expressing field interactions as the exchange of particles was first proposed. The idea has been, one might say, extremely successful, at the cost of the development of theories of incredible mathematical sophistication. The quantum theory of fields is now a very well-developed speciality in physics, but it leaves us with a tantalising conceptual problem. The particles which are exchanged in interactions, say, the photons that are exchanged in an interaction between two electrons, are not identical with the photons, the flux of which is the light with which we are familiar. These photons are virtual, that is, they exist in and only in the interaction, if they exist at all. Furthermore, as imagined, they have properties which differ from the familiar properties of the photon of light. They are like light quanta, but not quite like light quanta. Are they real?

Recently, the idea of using the analogy between the light photon and the photon of quantum electrodynamics as a basis for developing theories of other kinds of fundamental interaction, the weak interaction, the strong interaction and even gravity has led to the proliferation of such 'virtual particles'. I think it would scarcely have crossed the minds of most physicists to ask about the reality of virtual particles, were it not for the use of the structure of reasoning through which the light quanta became the models for quantum electrodynamics. In quantum electrodynamics, the virtual photon is modelled on the real photon, if I may be permitted to put the matter that way. Then weak interaction particles, the w+ and w-, and z_0 particle are modelled upon the virtual photon. They are all species of the same genus. Then, in a reversal of the reasoning which led to the conception of the virtual photon, the idea of a real w particle, or a real z particle seemed to be a natural development from the quantum field theory of the weak interaction. The programme for hunting the w's and z's was defined, and in the manner in which such events are achieved, they were eventually 'discovered'.

I believe that this pattern of reasoning which is characteristic of quantum field theory was at least in part responsible for raising the question of the reality of the intermediate vector particles which carry the forces of interaction. If there are real versions of these particles, then surely there is some sense to the reality of the particle as the physical bearer of the field ([6.10]).

A clear formulation of the idea that there is a distinctive set of properties, the behaviour of which defines the subject matter of physics

first appears in the seventeenth century. At that time the perceptible attributes of material things were classified as primary or secondary depending on their relation to human sensibility. Those which existed only in the act of perceiving were classified as secondary. Those which were thought to exist independently of the perceptual capacities of human beings were taken as primary. Galileo [6.17] seems to have so tightly tied the primary qualities to the science of physics as to make the one definitive of the other. Secondary qualities were marked by the way that they varied in quality, intensity and duration with the state of the human perceiver. Locke [6.29] completed the philosophical treatment of the distinction by carefully analysing the relation that must be supposed to obtain between secondary qualities, such as the power of a body to induce a colour sensation in a human observer, or an observable change in another material body, such as the power of fire to melt ice, and states of material bodies by virtue of which they had these and other powers. He sharply distinguished between ideas and qualities. Ideas are mental, including, for instance, sensations of colour. Qualities are material, including the properties of coloured things. This distinction enabled Locke to come at the distinction between primary and secondary qualities by a different route from that followed by Galileo. Ideas of primary qualities resembled the qualities as they existed in the material world. But the ideas of secondary qualities did not. Red, as a perceptible quality, does not resemble whatever property it is that causes a human being to see an old Soviet flag as red in hue. Generalizing the theoretical use of the concept of primary quality, Locke took the qualities that 'in the material body' caused corresponding ideas of secondary qualities as just those which are central to the conception of matter as it is used in the science of mehanics. All this is tied together by the thesis that the quality in the perceived thing that corresponds to the idea of colour, say, that is the secondary quality itself, is nothing but a power, a power to induce the relevant sensation. What the word 'red' refers to in the thing that is seen as red is a disposition. But it is grounded in an occurrent state of the perceived thing. According to this metaphysical scheme that state must be some combination of primary qualities.

For the scientist-philosophers of the seventeenth century, physics was mechanics. It was the study of the primary qualities of material bodies. Friction, for instance, as a mechanical disposition, must be grounded in the atomic structures of the interacting bodies. Mechanics, the basic science, was based on an absolutist metaphysics. Locke's philosophical account of the foundations of physics required two main categories of concepts. One set of concepts were relational. Many of the qualities of material things are dispositions to cause perceptible effects in a human being or in other material things. Whether they are activated or not depends on the contingent existence of suitable targets for their activity.

The other category of qualities was absolute. The properties on which the dispositions are grounded are primary. Primary qualities are so defined as to be independent of the relations between the material things which possess them and human beings or to anything else. Boyle [6.9] sums them up as the 'bulk, figure, texture [arrangement] and motion' of the elementary material things or corpuscles. The word 'corpuscle' was preferred to the word 'atom' by the sophisticates of the period, since it left open the question of whether the constituents of matter that were elementary for chemistry or mechanics were truly atomic, that is, indivisible in principle. Though Newton listed many dispositions amongst the primary qualities of matter, he shared the assumption of his contemporaries that there were *some* absolute physical properties. In the second edition of the *Principia* the list of the mechanical properties of matter are a mixture of the occurrent and the dispositional. Newton (1690) writes of the 'extension, hardness, impenetrability, mobility, and inertia of the whole [body] which 'result from' the corresponding properties of the parts. To have inertia, says Newton, is 'to be endowed with certain powers' [6.39]. Inertia appears in the list of primary, mechanical properties as the power to resist acceleration. But inertia is not mass in Newton's metaphysics. Mass is an occurrent property. It is that which grounds the disposition identified as inertia. To give mass its occurrent character Newton defines it as 'quantity of matter'. Since the mass per unit volume differs from material to material, a universal matter, serving as a basic common substance, would have to exist in different states of diffusion. In a substance of low density the matter is rarefied, while in a substance of high density it must be compressed. One physical scheme to accommodate this difference would be basic atoms in a void with more or less pores between them. There would be fewer such atoms in a given volume of a light substance than in a similar volume of one that was more dense. Newton seems to favour this account. The basic atoms would be full, and so of uniform density. Lacking pores they must be incompressible and impenetrable. I have emphasized above the problem this thesis raised for Newton's general mechanics.

Though most of Newton's primary qualities are dispositions, they are nevertheless absolute in one of the dimensions on which the notion of the absolute figures. In Rule III Newton asserts that they 'are to be esteemed the universal qualities of all bodies whatsoever' whether or not they are 'within the reach of our experience'. As primary qualities they are not relative to human sensibility, but by the same token they are a mix of the relational and the absolute. In Newton's scheme mass, inertia, extension and mobility must exist even in a body wholly isolated from all other material beings. It seems to follow from the definition of mass that Newton's physics includes at least two absolute properties of matter. The

quantity of matter would seem to be unaffected by the presence or absence of other material things. Since the quantity of matter of a body is related to its spatial extension, and that to absolute space, it would seem that extension and mass are both absolutes in Newton's scheme. The close conceptual tie between absolute space and mass is further underlined in Newton's argument for the intelligibility of the concept of absolute motion:

> if two globes, kept at a given distance one from the other by means of a cord that connects them, were revolved about their centre of gravity, we might, from the tension of the cord, discover the endeavour of the globes to recede from the axis of their motion.
>
> ([6.39])

By testing to see in which direction impressed forces bring about the greatest increase in that tension, we can find not only the angular velocity of the globes in absolute space but also the true plane of the motion with respect to that space. To suppose that a force will appear in the cord when the globes are set rotating, Newton must be assuming that the masses of the globes are unaffected by the absence of all other matter. The masses are absolute qualities. If mass is a quantity of matter, then indeed that assumption seems natural and also inevitable.

The generality with which Newton uses the notion of 'power' is evident in Query 31 of the *Opticks*.

> And thus, Nature will be very conformable to herself and very simple, performing all the great motions of the heavenly bodies by the attraction of gravity which intercedes those bodies, and almost all the small ones of their particles by some other attractive and repelling powers which intercede the particles.
>
> ([6.40])

There is yet another root idea in Newton's conception that gravity cannot be a primary quality because it suffers 'intensification and remission of degree'. So there must be a more basic power, 'an agent acting constantly' which is the absolute, because non-relational element, in the physics of gravity.

Mach's (1883) criticism of Newton's metaphysics is usually presented as an attack on the assumption that mass is an absolute property ([6.32]). But Mach's argument develops in two steps. He first shows that mass is best considered as a relational property in his analysis of the basic laws of mechanics. The argument goes as follows: consider an impact of tensions. The body A is falling under gravity. When the string joining it to the body B, resting on a smooth surface becomes taut, A will decelerate and B

accelerate. Since the string is taut at the moment of 'impact' the force decelerating A will be equal to that accelerating B, so Mach argues. Let that force be *'F'*. Then if the mass of B is m_b, the mass of A is m_a, and the accelerations f_b and f_a respectively, the equation of motion for the whole system is $m_a.f_a=-m_b.f_b$

Mass appears here, and in all other contexts of mechanics, as a ratio. In this case the ratio is equal to the negative inverse of the quotient of the accelerations. Mass and inertia are the very same relational disposition. Given this prior analysis, Mach's treatment of the experiment of the globes (and of the more complicated argument of the thought experiment we call Newton's bucket, which involves a refutation of the Cartesian conception of locally real motion) in which the assumption of the persistence of inertial properties into the isolated system of the globes is entirely consistent. It simply involves the generalization of the relationality of the mass concept to the components in the simple system of the impact of tensions to the structure and contents of the universe as a whole. Mach completes a trend that began in the sixteenth century, a trend to replace absolute versions of the properties of material things with relational properties. Not only are these properties dispositions, manifested only in the interactions between material bodies, they are also relational in the sense that they are not grounded in some intrinsic property of isolated material individuals but in their relations to all the rest of the bodies of the universe.

One can tie together the seemingly disparate mechanics of Newton (read relationally) with quantum field theory by the realization that there is a common structure to their deep ontologies. In what sense do *any* of the 'particles', actual or virtual, exist? It seems obvious that only a dispositional account of their manner of being makes any sense. By that I mean that our claims about the world-in-itself made on the basis of the experiments by which apparatus, has (permanently) a disposition to display itself in such and such a way in the behaviour of that apparatus. Or to put it in Popper's terms only the set-up has propensities to yield this or that phenomenon. The phenomena are ephemeral, but it is they which are particulate or wavelike or whatever it might be. In this treatment we have both of Bohr's famous principles, that of complementarity and that of correspondence. Complementarity because set-ups which exclude each other produce, as a matter of fact, disparate and complementary phenomena; correspondence because the state of an apparatus-world set-up can be described for a human community only in the terms made available in classical physics, the physics the concepts of which are paradigmatically defined by the things and events of the ordinary world.

CHAPTER 7

The philosophy of science today

Joseph Agassi

THE PHILOSOPHY OF SCIENCE HAS A REMARKABLY LOW STANDARD

Science began in Antiquity as a branch of wisdom, and philosophy (= the love of wisdom) was distinguished from wisdom only by philosophers. Cultivators of science in its early modern times (*c.* 1600–1800) called themselves philosophers, and their activity was called not science but natural philosophy. What we call today the philosophy of science includes the theories of knowledge (epistemology) and of learning (methodology), as well as the study of the principles of science (metaphysics, the philosophy of nature). The first two disciplines were at the time neglected as they were considered marginal; the third, metaphysics, was deemed distinctly dangerous. Natural philosophers did not consider their work impractical; they called themselves 'benefactors of humanity', as they were convinced that their activities, in addition to their intrinsic merits, will bring peace and prosperity to the whole world. But they insisted that the practical aspects of science, significant as they surely are, can only appear as by-products, not as the outcome of study directed to any goal other than the search for the truth: any other goal will render research biased and so worse than nothing.

It is not that applied science evolves all by itself, as the application of knowledge for practical purposes certainly requires efforts, including research. But the research for any practical purpose need not, it was taken for granted, be a search for knowledge. To make this clear, it may be useful to contrast the classical, typically eighteenth-century view with today's view: today we recognize within science not two but three

categories; we recognize basic research in addition to the classical pure and applied research, where pure research is disinterested and applied research is the use of the fruits of pure research for practical ends; basic research is pure research directed at material which is not very interesting in its own right but which is expected to be very useful in practice. There is little doubt that today research claims prestige for itself because of its potential usefulness. That is to say, all research is claimed to be more-or-less basic.[1] In the classical vein this was unthinkable, the value of science was deemed almost exclusively personal and research was deemed edifying.

Obviously, of the many thousands of citizens engaged in research proper, most are engaged in small tasks—which Thomas S.Kuhn has labelled 'normal'. And, he stresses, normal science is practical. He probably means by this that normal science is all practical, but let us admit that it can also be basic. The practical attitude to science is very modern; it is at most the result of the industrial revolution, and so nineteenth-century at the earliest; more likely it is post-Hiroshima. Kuhn is a historian of science and so he should know the obvious fact that normal science in the eighteenth century was more for individual entertainment than for practical ends. This was not always so: anyone familiar even with the mere illustrations in the literature in the history of science in the eighteenth century will know that. This is reflected in the third edition of *Encyclopedia Britannica* of the early nineteenth century. The article 'Science' there is extremely brief, reporting that an item of knowledge belongs to the body of science if and only if it is certain. Though the article gives no instances, clearly, the best instances are either from logic and basic mathematics or from extremely common and undoubted experiences, though, of course, some high-powered scientific theories should count as well. Today, incidentally, it is generally acknowledged that of these seemingly most certain items, none is exempt from doubt and revision (except perhaps logic; this is still a contested matter). Next to that brief third-edition *Britannica* article on science is a long article on science as amusement, in which the contents of a famous popular eighteenth-century book (by Ozanam) is reported. We would recognize today the contents of this article as vaguely within the domain of high-school sciences, as it includes somewhat amusing experiences with mechanics, electricity, magnetism and the like. Probably these two articles were not conceived of together and they were put together by sheer lexicographic rules.

The picture which emerges from this description presents a concern with science which is pre-critical. It was at times purely intellectual, at time practically oriented, always with great implication for life in general, for daily life and for peace, but with hardly any concern for the problems and issues in the philosophy of science as recognized today. Today, many

of the concerns of the field, epistemological, methodological and metaphysical, are traced back to writers of the classical era, especially David Hume and Immanuel Kant. There was a major difference between these two thinkers. Hume is typical of his class: he was a private scholar who was clearly concerned with the social sciences (politics and economics, in particular), whose contributions to the philosophy of science he himself saw as marginal and preparatory. Not so Kant, who was most uncharacteristic; he was a university professor, who was on the side of science, and who was reputed to be a polymath proficient in fourteen different branches (some of which he inaugurated as academic subjects, such as geography and anthropology). He was still primarily a philosopher, and even primarily a philosopher of science.[2]

It is hard to examine this, quite generally received, assessment, since the expression 'the philosophy of science' is new. To repeat, traditionally the word 'philosophy' designated learning in general and empirical science in particular. After the defeat of the French Revolution, some fashionable reactionary philosophers swore allegiance to unreason. Other, more old-fashioned philosophers understandably attempted to distance themselves from the new advocacy of unreason, and one way they did this was by naming their own views 'scientific philosophy'. This name usually designated mechanistic philosophy; its adherents considered theology to be typically metaphysical and so they branded all metaphysics evil; this enhanced their claim for scientific status for their own, mechanistic metaphysics. This way the philosophy that upheld the traditional esteem of reason centred mainly on science and on reasonability in the moral life of the individual and the nation. It naturally tended to centre increasingly on epistemology, methodology and rational metaphysics as a main tool to combat unreason. The philosophers of unreason had—still have—their own philosophy of science, but this is scarcely recognized: the philosophers who defend reason against the attack on it from the advocates of unreason took a monopoly on science and its defence.

The philosophy of science thus evolved into a specific activity of philosophers of the rationalist persuasion—the activity of defending science against its detractors. This explains the poverty of the field today: today science has no worthy detractors to combat; and no dragons to slay, no heroic deeds.

Even the philosophers of science themselves are aware of this fact, as they defend science not only by singing its praise, but also by attempting to solve problems in epistemology and in methodology, and by seeking newer and better arguments to combat metaphysics with. They do this as a mere pious act, paying no heed to the possibility that the problems they pose are insoluble, at least insoluble as long as they are presented in the traditional manner and settings. They cling to the pre-critical, optimistic

view of science in the face of the risks to the very survival of humanity which scientific technology has originated: they relegate these risks to the new field of the philosophy of technology (which is less than half a century old), as if their philosophy of science does not include the philosophy of technology and as if their philosophy of science does not credit science with scientific technology as a great achievement. It really is a cheap trick to admit to the field of the philosophy of science the praise for science as the source of the benefits from scientific technology and its great achievements, and to banish to the philosophy of technology the possible and actual ill-effects of the same scientific technology.

David Stove is exceptional. The efforts to solve the traditional problems of the philosophy of science, he says, are commendable even if these should turn out to be insoluble. For, he explains (in his book against those who have given up the traditional struggle, including Sir Karl Popper and Thomas S.Kuhn), the struggle is the ongoing defence of science and thus of traditional rationalist philosophy and thus of rationalism as such.

This is a charming admission, but of a position that is obviously pathetic.[3]

PUBLIC RELATIONS FOR SCIENCE IS MEANINGLESS

In the year AD 1600 St Roberto Cardinal Bellarmino consigned Girdano Bruno to be burnt at the stake—allegedly because he taught that the universe is infinite, so that in all likelihood there exist other worlds like ours. Later on the said Saint issued an official threat to Galileo. Science was then rightly militant. Today science is triumphant; even the Church of Rome has recently admitted the superiority of Galileo's case over that which was contrived against him and officially endorsed there and then. However embarrassing this repudiation was, science became too strong to continue evading it.[4] Today, science surrounds us and appears on all levels from the sublime, through the mundane to the abject.

In the sublime mood science is what Bertrand Russell called ([7.53]) 'Promethean madness' and what Albert Einstein considered to be the scientific undertaking: 'tracing the Good Lord's blueprint of the universe'. In the mundane world of the modern industrialized metropolis, the impact of science on the intellectual, political, social and technical aspects of life is overwhelming; especially, the impact of scientific technology is so very prominent. The abject aspect of the impact of science on daily life has attracted a certain kind of philosopher of unreason, whose hostility to reason is expressed as a hostility to science, transformed into a hostility to scientific technology—on the

grounds of prophecies of gloom and of apocalypse that should be blamed on scientific technology, *the* cause of the alienation of Modern Man. These prophets of unreason identify science with the foolish attempt to conquer and subjugate Nature and they are confident that Nature will soon avenge this treatment by devastation. They advocate the replacement of the Western harsh, indifferent attitude to Nature with a soft, intuitive, irrational, oriental attitude. This mixture invites very urgently the sifting of the grain from the chaff.[5]

This quick survey of the impact of science on society that goes from the sublime to the ridiculous, has omitted the ridiculous. This dimension is normally absent: science is no cause for levity. The entertainment world is as much under the influence of science as any other component of our small universe, in its shaping of our tastes and opinions and values and in its stupendous media technology. But not as an object of hilarity; even as sedate entertainment it is almost entirely confined to the juvenile. Yet they raise in a fresh manner the question, what is science? The question seems to require an answer that is easy to apply to what we usually call science, including high-school science and nuclear physics and electronic engineering. This is an error: we may have a thing and the received model of that thing, and the two need not agree. In the literature on social anthropology, this is taken for granted. In that literature, the paradigm for the difference—between a thing and the received idea of it—is the difference between magic and the received idea of it: in every society that has been described by some anthropologists, there are magicians, and yet (unless we deem the scientists as powerful magicians as did Sir Francis Bacon in the early seventeenth century), we all agree that real live magicians never fitted the characterization of magic admitted in their society (except possibly contemporary modern society). Magicians like Merlin do fit the image of the magician, but they never existed (except perhaps among modern scientists). Do the modern scientists fit the image of science?

It is the image of science that is rather ridiculous, as it is put forward by the spokespeople for the public relations of science. This is not peculiar to science. The practice of public relations evolved unawares and uncontrolled as a part of the advertising world of the free market, where the shortest of the short-term interests govern, so that the most cynical opportunists set the tone. This is harmless enough when pertaining to the sales of soap, but not to the sales of the higher things in life, be they the arts, the sciences or religion. Whoever the individuals are who take upon themselves to express the social concerns of science, they are these days powerful individuals and they control the appointment of suitable individuals to the positions of spokespeople of science. The leading positions in

this matter are well-paid professorships in the leading universities in the subject called the philosophy of science.

In brief, official philosophy of science, the philosophy of science boosted by the scientific establishment, is much less tolerable than the commercials on television which sell soap and other cosmetics. They are as remote from the Promethean madness of the search for the secret of the universe as eroticism is from the (intellectual) love of God.[6]

If we grant this, and it is hard to deny it as we will soon have the occasion to notice, then we may begin by denying that there is anything more specific to science as such than to cosmetics as such. And the best characterization of science that can be given is in that vein: science is the Promethean madness, the attempt to trace God's blueprint of the universe, the search for the secret of the universe.[7]

SCIENCE IS A CULTURAL PHENOMENON

There are some immediate, obvious objections to the view of science as a quest, and they centre on the missing object of the quest and on its trail, expressed in the following two questions. What will satisfy the scientific quest? Which way does one turn to be on its trail? These questions are reasonable and should be taken seriously, but they are presented as objections, and as objections, I will now show, they are residues from the pathetic public-relations department—by illustrating their immediate socio-political implications—on the assumption that there are no competitors within human culture.

The first objection is dominant in the semi-official literature on the matter: what exactly are we in search of? Are we in search for information or for knowledge? If for mere information, will any information do? If yes, why not be pleased with the information contained in primitive lore and in Scriptures? This series of questions looks so straightforward, but it is not. It begins well and degenerates: what exactly are we looking for? This is the right question even though obviously we do not know: we know what we look for when we look for a lost penny, but not when we look for a masterpiece while roaming in a foreign museum, much less when we seek the secret of the universe. The question is right, but we should not expect too much for an answer: anything remotely resembling a possible answer may be a tremendous excitement. But look where the series of questions ends. It ends with an insult to the competition. This is not serious; it is public-relations frivolity—especially since repeatedly the self-appointed public-relations spokespeople of science often find the quest formidable and even exasperating, so that they finally settle for the mere physical comforts

that science-based technology has to offer to the modern world. (The leading public-relations spokesperson of science in the previous generation was Rudolf Carnap, the famous debunker of all speculations; his *magnum opus* was his *The Logical Foundations of Probability* of 1950; it starts with the formula for finding the truth about the world and ends by giving up the task, with the excuse that science is a mere instrument.) And so, when the circle is closed and science is praised as a mere instrument, the conclusion is not drawn but remains all the same: the mere physical comforts that science-based technology has to offer the modern world is superior to the primitive lore and to the Scriptures. This is hard to take seriously. Primitive lore and the Scriptures do not compete with modern science-based technology as conveyors of physical comforts, but they still are very interesting and deserve attention in many ways and on many levels. This is the end of the objection from the hostility to the idea of science as a quest from popular lore and the Scriptures: the quest is obviously not replaced by the study of popular lore and of the Scriptures; rather, the study is a part of the quest.

The public-relations spokespeople do not allow themselves to be dismissed so easily, and they respond with forceful objections to the dismissal here suggested: they want reason, namely science, to be the guide for life; they want science to offer but better technology and better education, and the two should go together (as the proper education for the next generation is essential for the technological challenges they will face), yet the competition will not agree. Admittedly taking the Scriptures as a science substitute is frivolous. Yet, however frivolous the competition is, its hostility to scientific technology and to scientific education must be taken seriously in the interest of the wellbeing of us all.

This rejoinder seems very serious and very responsible, but it is not. Responsibility will be served if the question of education and of the place of technology in the modern world be discussed not apropos science but apropos the design of a better education policy, the study of education and its purposes. And the same holds for the problems that are specific to high-tech society. Here we are discussing science, and as the search for the secret of the universe, not the implication this has for education and for the training for high-tech. True, science shares with other domains the search for the secret of the universe, including magic and religion. Do the public-relations spokespeople of science want to distinguish between the search conducted in a manner becoming science and in alternative ways? Or will the comparison suffice of the results of the search along different lines? Today it is agreed that the results tell the important tale: by their fruits ye shall know them. Do we know the difference in the results? Of course we do: even the most ignorant among the public-relations spokespeople of science have no difficulty in

telling a magic text from a scientific one! To be precise, the semi-official literature of the public-relations spokespeople of science is not that advanced: only a few philosophers of science discuss magic proper in a manner which is up to the standard of current social anthropology, the scientific field of study which retains an exclusive claim over magic. Rather, the semi-official literature of the public-relations spokespeople of science is concerned to a large extent with the unmasking of items of pseudo-science as merely pseudo, namely, not the genuine articles they masquerade as.

SCIENCE NEEDS NO PROMOTERS

It should be granted that this is more challenging: the public-relations spokespeople of science can easily distinguish a genuine amulet or talisman from a page of a scientific paper, but lamentably all too often they cannot distinguish a phony page of a manuscript that deserves publication in a scientific journal from one that is not. This is why the public-relations spokespeople of science are never invited to act as referees for judging the merits of scientific research any more than the public-relations spokespeople of a financial concern will be asked to adjudicate on matters financial. This is why the public-relations spokespeople of science are so pleased and so proud when a scientist proper joins their ranks, even though they should know better. For, a scientist can contribute to the philosophy of science without joining the ranks of the philosophers, as many scientists often do. Hence, scientists become philosophers only as an admission of defeat as scientists, often after retirement. Max Born, the great physicist of the early twentieth century, who was also a somewhat less-great public-relations spokesperson of science, said that all able-bodied researchers should devote all their energies exclusively to science and permit themselves to turn to philosophy, if at all, only after retirement.[8]

All this sounds rather evasive, yet it is the heart of the matter: analysing the means for distinguishing between the genuine research from the pseudo sounds a reasonable task, yet it clearly is very questionable, and probably it cannot be done: even scientists of the best repute are not very good at it. Proof: young Albert Einstein was deemed phoney by many scientists, and he was taken as suspect for well over a generation—while those who took him seriously debated hotly the question, was he right?

The great historian of physics, Sir Edmund Whittaker, who was himself a serious scientist (he was the Astronomer Royal for Northern Ireland) was hostile to Einstein all his long life, and as late as in the mid-century, long after the heated debate had subsided, he declared that there never

was an Einsteinian revolution and overlooked the heated debate completely. In a review of Whittaker's book Born said, I was there, I witnessed the heated debates and took part in them.[9]

To return to the items that may be masqueraded as parts of science. These items are, among others, magic, theology and metaphysics. What is so pathetic about all the many studies dished out year in and year out by the public-relations spokespeople of science is precisely this: were they right, then there would be no regular problem in refereeing, and in the rare cases of such a problem, these very public-relations spokespeople of science should be the experts to consult. Such cases do not exist.

To be precise, one such case does exist: in the long history of the public relations of science, one such spokesperson was invited to speak as an expert on the matter at hand. It was the second 'monkey trial' so-called, the court case a few decades ago, in which a judge in Little Rock, in the State of Arkansas, USA, was called to adjudicate between the education department of that state and a religious sect which demanded that the official biology text books should include proper reference to scripture. It is a priori obvious that both parties were lamentably in the wrong: the education department was in error in proscribing such reference and the other party was in error in trying to bring in, not the Scriptures, but a certain dogmatic attitude.[10] The judge had little choice but to side with the education department, simply because the public-relations spokespeople of the religious sect in question were even more inept than the public-relations spokesperson of science who was invited to speak for the department. He argued that the religious are dogmatic and the scientists are not. Even apart from the fact that many individuals are religious scientists, this is a naked falsehood: there are non-dogmatic religious sects and dogmatism is lamentably too common among scientists, religious and non-religious, and more so among science teachers. When it comes to the curse known as science-education inspectors, it seems that for them dogmatism is obligatory, though, as many obligations, it is at times not carefully observed.[11] This is no complaint about the judge: he was facing in court dogmatism on both sides and had to choose the lesser evil. In that Arkansas court on that day, science appeared the lesser dogma and the lesser evil; but with the help of the public-relations spokespeople of science this will soon change—unless something is done about it. These public-relations spokespeople of science are not powerful at all, but they may do harm anyway, as they cover up some powerful evils: the more powerful science is, the more success it brings about, the more the dangers of its abuses, and unchecked it will be abused. This, after all, is the major lesson we learn from all science fiction, and Mary Shelley, H.G.Wells and Isaac Asimov spun yarns to let us absorb this lesson. Except that under the pious guidance of the public-relations spokespeople of science, readers of

science fiction take the lesson to be mere fiction with no moral to it or as fiction with futile moral against the abuse of magic, not a real moral against the abuse of science.[12]

We have arrived back at the claim of the self-appointed public-relations spokespeople of science that the evil of magic is in its masquerading as science, in its being pseudo-scientific. This is most parochial as an attitude: most magicians and theologians, even most metaphysicians, operated (and still do) in societies in which there is no familiarity with science so that they do not masquerade as scientific and so they do not qualify as pseudo-scientific. Even cargo cults, the magic rituals involving wooden copies of aeroplanes and other modern artefacts in the hope of inducing the gods to grant them to the worshippers, scarcely qualify as pseudo in any sense.[13] To say of Moses the Law-giver and of Jesus Christ that their theology masqueraded as science defies the imagination. Only in response to the assertion of Maimonides, that Moses the Law-giver was a scientist, could anything like the charge of masquerading be launched—validly or not.[14] *The* philosophers of science, however, that is to say, the semi-official public-relations spokespeople of science, are not interested in all this: they care little about societies overseas; they are here to advertise science here and this task includes the discrediting of the competition here. They therefore permit themselves at times to be agreeably tolerant to theology and to metaphysics—after proof is issued to their own satisfaction that the parties involved do not compete with science. Usually, that is, theology and magic are deemed competitors, and then *the* philosophers of science, that is to say, the self-same semi-official public-relations spokespeople of science, find themselves acting as bouncers for the exclusive club of science. The leading sociologist of science, Robert K.Merton, prefers the term 'gate keepers', as he deems it the less offensive of the two; it is more offensive, as will be clear when we find the answer, which should guide the bouncer, to the central question of the philosophy of science: who is and who is not a *bona fide* member of the club? What is science? Is there a quality of science that sets it apart from what the bouncers consider as the competition? For, clearly, science is open and gate-keeping makes it a closed club.

SCIENCE IS NOT SUPER MAGIC

What is science? Science is a body of knowledge; science is what scientists do *qua* scientists; science is a tradition; science is any empirically involved research activity; science is a faculty in the university. All these answers are true and meet the question, yet they are highly unsatisfactory. Hence,

the question was ill-put. Here it is in its proper wording: what is the essence of science?

This is a tricky question; without entering the hoary matter of the critique of essentialism we can re-word it: what differentiates science from……? Taking it seriously requires the study in depth of many competitors to science. The study of alien cultures is, of course, highly recommended and even the bouncers will not object to it unless it is done from the viewpoint of the competition. Yet controversy about alien cultures abounds in the scientific departments devoted to it, and consequently the task of characterizing science in opposition to them gets increasingly harder. Example: is Claude Lévi-Strauss, who has created a revolution in the current view of myth and of magic, is he a bouncer or a competitor? He says he is a friend of science, a scientist indeed. Is he? The question is very difficult to settle and the anthropological literature is still struggling with it.[15] Let us try to alter our strategy, then. Can we look at science rather than at the competition and find there some clear-cut characteristic that sets science clearly apart from all the competitors? If so, what is it?

This is the problem of the demarcation of science as semi-officially understood.[16] The most traditional answer to it, to repeat, is that science is a body of theories, and what characterizes them is their certitude, our ability to prove their perfection and finality. The more modern answer is the theory that science is a prestigious social class which lends prestige to its ideas. These two answers are contested these days, though the first is advocated mainly by philosophers of science and contested mainly by sociologists and historians of science, and the second suffers the reverse role—we have here two groups of self-appointed public-relations spokespeople of science competing for the same territory. Let us take the first answer first.

In the twentieth century the impact of logic led to a shift on this matter. The scientific character of a sentence shifted: it was deemed not proof but provability. Now generally one cannot know if a sentence will prove true or false before it is compared with experience. So, a sentence was deemed not quite provable, but merely decidable; a sentence is decided if it is either proved or disproved.[17] This doubled the number of entries: not only a proven sentence but also its negation is scientific, as the negation of a proven sentence is disproved, and the couple of sentences taken together is decidable. Now the claim was that though generally a sentence cannot be declared a priori provable, it was declared that every well-formed sentence is a priori decidable. The justification for the relaxation of the criterion of demarcation of science to the extent of letting the negation of scientific claims be scientific was the wish to corner the competition once and for all by permitting the competition to contradict science openly. If the

competition does contradict science, they will put themselves to ridicule, and if not, we will be able to expose them as saying nothing. The very idea that one can permit the competition or not, and decide that they say something or not, shows that the advocates of this view took anti-science to be passé, that they were serving science in the supposition that it is winning anyhow. In any case, they met the surprise of their lives when they learned (from Kurt Gödel) that even in mathematics decidability is unattainable. In computer science it is at times an empirical affair: many tasks given to a computer for deciding the truth or falsity (called the truth value) of a sentence are performable, and demonstrably so; at times the demonstration is purely abstract, as when the time the task takes to complete is much too long. And some tasks are not known to be performable or not. And then, if such a task is given to a computer, then, if the computer finishes the task, it is performable and the truth or falsity of the sentence in question is decidable; but until the task is completed it cannot be decided whether the task will be completed soon or not.[18]

At this juncture the story of contemporary philosophy of science gets much too involved. First, there are modified conceptions of the empirical character of science: the requirement from a sentence that may claim (empirical) scientific status is lessened by leaps and bounds. The exercise of the lessening of the requirement is curious: the input into it increases all the time, yet the output becomes less and less satisfactory, to the point that its own advocates are too unhappy about it to conceal their displeasure with it. Briefly, the idea of certitude is replaced by probability, by a limitation on the domain of the validity of the proof, and by the abandonment of the very concept of proof, which imports finality, in favour of the concept of relative truth.[19] What all of these substitutes for the idea of decidability share is the following incredibly fantastic idea: though a sentence is not usually decidable, its scientific character is. (In other words, though finding the truth or falsity of a sentence is not generally assured, the truth or falsity of the claim that it is scientific is easily assured.) This is a fantastic idea, since one way or another science is linked to truth, no matter how tenuously. Yet it is accepted upon faith. What accepting a sentence on faith means is not clear, but its political implication usually is: the society of the elect are known by their faith.

This is how the first answer, the idea of decidability, upheld by philosophers of science, slowly degenerates into the second answer, the idea that science is a social status of sorts, upheld by the sociologists of science.

Can we ignore all this? Can we ask as curious observers, what is the root of the success of science? Is there some activity peculiar to science?

SCIENCE IS PUBLIC AND EMPIRICAL

Our question has undergone some transformations. First we asked, what is science? This was replaced by, what is the essence of science? And this was translated to, what differentiates science from other intellectual matters? And this was narrowed down to, what characteristic is peculiar to science? And rather than go over the same exercise yet again we should translate this into the following, final wording: what is the specific characteristic of science? (The word 'specific' in the question by tradition hides an essentialist gist, but let us not be too finicky.)[20]

There are two very generally accepted answers to this last question, what is the specific characteristic of science? This would be very comforting, except that the two answers do not overlap. The one is, science is public; the other is, science is empirical.[21]

Take the public character of science first. The claim made here is that most intellectual activities are esoteric, closed to the general public, that entry is conditioned—whether on some natural gift or some specific preparation not given to all or both. Is this true? If so, then by what virtue do the public-relations spokespeople of science dare bounce people who wish to be or appear scientific? More than that: if science is open—exoteric—then why does science need public relations in the first place? It needs recruiting officers, talent scouts, instructors; but why bouncers? What does it matter to science that some esoteric groups appear to be exoteric and other groups have esoteric reasons to oppose science? What does it matter to science, asked Einstein, if this or that church opposes it? If it is necessary to expose and unmask those who masquerade as scientists, is it not best to do so by examining the question, how open are their clubs? Perhaps the bouncers suggest that this is not such a good idea as it may deprive them of their jobs; if so then they are disqualified from debating this question because of a conflict of interests![22]

The second answer is that science is empirical. Now surely Sir Karl Popper is quite right when observing, as a matter of historical fact, that astrology and alchemy and even parapsychology, are empirical as well. The public-relations spokespeople of science are outraged by this observation, and they protest that the empirical evidence in question is highly questionable, and often it is simply lies. This complicates matters immeasurably by raising two tough questions. What evidence is not questionable? Are all scientific reports honest and all parapsychological ones lies? It has been reported that some people pose as parapsychologists and are liars; it has also been reported that some people are genuine parapsychologists and are not liars. Are the reported liars not simply pseudo-parapsychologists? Since people who falsely

call themselves scientists are unmasked as pseudo-scientists, and science is free of responsibility for them, surely the same privilege should be granted to parapsychology! The question here is not who is a liar (this question belongs to sociology, to criminology, to cultural history), but, what grants a theory the right to scientific status, namely, what is the characteristic of science? Supposing it is claims to empirical character. Are we to alter this supposition in the light of criticism to say that it is the employ of scientific empirical evidence?[23] This, surely, is hardly helpful, unless we know what makes evidence scientific. Whatever it is, two obvious, extreme answers are unacceptable. The one is that scientific evidence is true: history is full of (historically important) empirical evidence that is known to be false. The other is that empirical evidence is *bona fide*. For it is undeniable that some parapsychology is *bona fide;* indeed, some famous individuals whose contributions to empirical science is unquestionable were known parapsychologists. William Crookes is the standard example for that.

The matter of alchemy or of astrology is even more complex: historians of alchemy and of astrology tell us that the better practitioners of these activities were *bona fide,* and that some of them even contributed to what is now deemed chemistry and astronomy.[24] And we have still not said whether all the *bona fide* empirical evidence should count as scientific. There is a vast literature, going back to the writings of Galileo Galilei as to this question. It is called the literature on theory-ladenness, and for the following reason: if empirical evidence is based on theoretical suppositions, then it may be false unless the suppositions are known to be true. Suppose they are known to be true. On what grounds? Suppose they are known to be true a priori? Then science cannot be said to be thoroughly empirical; assuming, as we often do, that no intellectual activity is utterly devoid of some empirical component, and empirical character ceases to be the differentiating characteristic of science. Suppose, then that the theocratical suppositions are known to be true on some empirical grounds. Then, are these free of theoretical supposition? If no, then the question returns full strength. If yes, then there is some empirical evidence based on nothing but experience. Can this exist? If so, do we have an instance of it?[25]

Public-relations spokespeople of science hardly ever stay to hear all of these objections. Usually they or their seniors are in charge of (politically significant) discussions and they curtail them long before they are exposed that much.[26] They have a strong technique to justify their impatience: no matter how abstract and distant from real life their discussion is, they sooner or later turn the complaint that their opponents are remote from real life. In real life, they intimate, science is successful. This success should be analysed. And profound analysis tells us that the success is predictive, i.e. it yields successful forecasts. Thus, if we have no

proof, we have systematic probability: the earthly success of science is too systematic to be merely accidental; rather, this systematic earthly success is due to the systematic success of science in its efforts to confirm its theories.

SCIENCE POWER WORSHIP IS HILARIOUS

The discussion thus leads to the question, how come science is so systematically successful in its efforts to confirm its theories? What is the trick? Can it be learned? Can it be emulated by parapsychology? The answer must be, it can be learned, or else the success would not be so systematic. How can it be learned? There are two answers to this question, that of the traditional philosophers of science and that of the sociologists of science led by Michael Polanyi and his follower Thomas S.Kuhn. The one is exoteric, and so should be able to describe the formula that makes science an ongoing success; the other is esoteric and describes the knowledge of the formula an ineffable personal knowledge of the trade secret which is transmitted by master to apprentice.[27] This is the worst aspect of the philosophy of science as currently practiced, as public-relations mulch: science is predictive success or it is nothing. If the worse comes to the worst, then scientists are better viewed as exoteric magicians who simply deliver the goods and no questions asked. But the trick is to take as much time as possible getting to the worst, and in the meantime perform the real function as bouncers. Let us review the discussion which leads to this blind ally and see clearly that it is but killing time, that the only serious, *bona fide* ideas involved in the time-killing activity are long dead.

There are two schools of thought in the establishment of the philosophy of science, inductivists and instrumentalists, so-called. Inductivism is the preferred view, as it suggests that scientific theories are probable, even if not provable. It is not clear what this probability of theories means, and, regardless of what exactly it is, it is not clear which evidence raises it and how. It will soon be shown that this is all sham. When inductivism is relinquished, its touchstone, the idea that the goodness of science is shown as it yields useful predictions, or probable forecasts, becomes more than a touchstone; it becomes the criterion of goodness: science, it is then suggested, is nothing but applied mathematics; its merit is practical. Consequently, it turns out, its merit is not theoretical but merely practical—it is merely instrumental.[28]

Assuming for the moment that the value of science is nothing but true forecasts does not yield the conclusion that all true forecasts are desirable. The approval of true forecasts runs against the very well-known very commonsensical facts, first, that some forecasts are

terrible and are better not fulfilled and second, that a true forecast may mislead.

There is no question that this is the case, and the public-relations spokespeople of science are not in the least unaware of it. They do not deny this either. They only ignore it. What this oversight amounts to is clear: we are in control and there is no reason to fear that our forecasts are alarming or that we are misled by them. This *is* establishment talk. The world is threatened by destruction from pollution, from the proliferation of nuclear weapons, from population explosion and from the ever-increasing gulf between the rich nations and the poor nations. But there is nothing to worry about. All will turn out to be well.

Query: is this a scientific forecast or false prophecy? It is neither; it is cheap public-relations mulch.

To see how unserious this mulch is one only needs see the low level of the current debates in the leading literature on the matter. The topic common to both inductivists and instrumentalists is the question, are there any items of empirical information free of theoretical bias? Is there any 'pure' evidence? Or is all evidence theory-laden?

The onus here is on the party that says there is 'pure' evidence: they should offer instances. There are none. The only candidates in history were Bacon's naive realism and Locke's sensationalism. Naive realism is refuted: the naive see the sun rise and set, and, to cite an example of Erwin Schrödinger, the sun appears as not bigger than a cathedral, which means, given some simple trigonometry, that the distance between east and west is less than one day's walk. In an attempt to replace naive realism in view of the criticism from Copernicanism, Locke revived sensationalism, claiming that motion is not perceived. It is. Sensationalism is refuted, anyway, by myriads of experiments. This is the end of that discussion.

The next discussions concern theories. There is hardly a debate between the inductivists who ascribe to theories informative contents and the instrumentalists who deny that and read the theories as a mere *façon de parler*. Rather, each struggles with its own problems.[29]

The theory of induction contains two competing sub-theories, which deal with the question, what kind of evidence confirms a given theory? They both violate the only rule of science universally endorsed within science since its enactment in the early days of the scientific revolution: both sub-theories do not confine their discussion to repeatable, (allegedly) repeated observations, but rather they refer to unique items of experience. In addition to this, each of these sub-theories is easily refuted by very simple arguments. A vast literature is devoted to these refutations in an effort to get rid of them; worse, still, as usual with public-relations spokespeople in a defensive mood, they do not state the difficulties they struggle with and so sound arcane.

The first of these two sub-theories of inductive evidence is the instantiation theory of inductive evidence: a scientific theory is confirmed by instances to it. What then, is an instance to a given theory? What is an instance to a theory of gravity? Anything falling? Decidedly not: a falling feather disobeys even Galileo's theory of gravity. What then counts? Rather than discuss gravity, the public-relations spokespeople of science discuss such generalizations as, 'All ravens are black', forgetting that when asserted, these are items of evidence, not theories. What, then, counts as an instance? Every item that does not contradict a theory is an instance of it, since theories can be stated as prohibitions: there exists no perpetual-motion machine, for example; no gas deviates from the gas-law equation, etc. And then every item that is not a perpetual motion machine instantiates the law of conservation of energy! It sounds very counter-intuitive to admit every non-refutation as an instance, since this invites all irrelevancies into the picture. This is known as Hempel's paradoxes (in the plural) of confirmation. The counter-intuitive character of this fact is taken to be powerful criticism of the theory, despite the obvious fact that the theory is anti-intuitionist and so its advocates should not be disturbed in the least by its counter-intuitive character. For, were it permitted to rely on intuition, then the intuition that the world is law-governed is strongest, and so it dispenses with the problem of induction *ab initio*. A vast literature is devoted to efforts to rescue the instantiation theory of induction from its (seemingly?) counter-intuitive character.[30]

The second sub-theory of inductive evidence has for its background the musing that the function describing confirmation is a unique [!] function of both theory and all [!] extant evidence and of nothing more—or, if not uniquely determined, at least all such functions must [!] conform to the mathematical calculus of probability.[31] The theory, if it can be called that, is that the desired evidence is that which renders a theory probable in accord with this musing. The musing has two advantages. First, it identifies the vague concept of probable hypothesis with the clear concept of conformity to the mathematical calculus of probability. Second, it offers a clear-cut estimate of probability—on the further musing that the probability of an event equals the distribution to which it belongs. Except that this musing has no room for distributions other than those offered by theories whose probability this musing should help us estimate.

But evidence does play a great role both in research and in practical life, the self-appointed public-relations spokespeople of science exclaim in exasperation. Indeed, this is so, and from the very start; what they have promised to expose us to is not this profundity but the answer to the questions how and why? They even overlook the more basic question, which is, does evidence play the same role in research as in

practical life? It is more than reasonable to assume that the answer to this question is in the negative. The public-relations spokespeople of science take it for granted that the answer is in the affirmative. So much so, that they refuse to ask it—or to hear anyone who asks it. For, clearly, investigators, be they detectives or scientists—from popular fiction or from real life—do pay great attention to minute details, as they must, and then, when their search is concluded, they ignore most of the minute details and blow up the others. How else can the small details of scientific discovery grow so large as to cover the whole of our city-scape?

When researchers—detectives or scientists—follow a clue, they do so at their own risk. Hence, science is not as successful as it looks. Even in fiction detectives do lots and lots of legwork that ends up in blind alleys. But when successful, results have to be confirmed, and their confirmations have to be easily repeatable. When the success in question is scientific, it matters little to the practical world what these are.

When the success is claimed to be worldly, then there are legal standards for confirmation, that philosophers of science assiduously ignore. In medicine, for example, a claim for success has to be repeated *in vitro,* then *in vivo* on laboratory animals, then on human specimens under specified controls, and then proved satisfactory by some complex standards.[32]

Is this not the inductive canon that the philosophers of science seek? No. It is not any philosopher's stone, but the real, human, limited, at times highly defective system. The established philosophers of science ignore it as it is no use to them in their self-appointed function as public-relations spokespeople of science, as self-appointed bouncers of the haughty club of science.

POPPER'S CRITIQUE OF INDUCTIVISM IS OVERKILL

Popper's critique of the instantiation theory of induction is simple: there are practices accepted in the scientific community concerning what counts there as confirmation, and these should be taken into account when a theory of confirmation is presented: not all instances confirm theories but, at most, those which were expected to refute it and failed. This is admitted obliquely by Carl G.Hempel, the chief discussant of the matter of instantiation and its afflictions, but not openly. Yet, he is not satisfied with the situation as he seeks a formal criterion for confirmation. He thus cannot fully admit Popper's (empirical) assertion

that at most only failed refutations of a theory confirm it, as failure is not a formal criterion.[33]

The more extensive criticism of Popper is directed against the identification of confirmation with some function abiding by the calculus of probability. This is surprising, since the probability sub-theory of confirming evidence and the instantiation sub-theory of confirming evidence are, of course, but variants of the theory of induction. (Indeed, the common way to dismiss the paradoxes is to dismiss most of the confirming instances as practically irrelevant by the claim that they scarcely raise the probability of the theory which, strictly speaking, they hardly confirm.) Perhaps he does so on account of its lingering popularity. For decades Popper presented criticisms of this idea, and it would have been dropped from the agenda, were the public-relations spokespeople of science able to exhibit some sensitivity to devastating criticism.[34]

First, says Popper, confirmation cannot be probability as it reflects the force of the evidence and not the informative content of the theory prior to evidence. Therefore, at least confirmation should be probability increase, not probability. (This, he embarrassingly adds, resembles Galileo's announcement that gravity is proportional not to velocity but to its increase.) And probability increase is certainly not a function abiding by the formal calculus of probability. The point is easy to demonstrate. Here is Popper's demonstration.

Let us write *'P (h)=r'* and *'P (h, e)=r'* to denote absolute and relative probability in the usual way; suppose a theory h_1 is absolutely probable and some evidence e_1 reduces its probability, whereas h_2 is improbable yet some evidence e_2 (which may be the same as e_1 if you wish) raises its probability, but not much, so that

$$P(h_1) \geq P(h_1, e),$$
$$P(h_2) \leqslant P(h_2, e),$$

yet

$$P(h_1, e) \geq (h_2, e).$$

Clearly, though h_1 is more probable than h_2 it is more confirmed by the evidence. The objection that this is impossible is groundless. Moreover, a model for it is easy to construct. Here is one.

Consider event E which is the next throwhof a die. Take the following cases:

h_1: E is not a 1.
h_2: E is a 2.
e: E is 1 or 2 or 3 or 4.

and

$e_1 = e_2 = e.$

Now,

$$P(h_1) = 5 / 6,$$

and

$$P(h_2) = 1 / 6,$$

so that

$$P(h_1) \geq P(h_2)$$

and

$$P(h_1, e) = 1 / 2.$$

and

$$P(h_2, e) = 1 / 4,$$

Now,

$$P(h_1) \geq P(h_1, e).$$

so that the evidence undermines h_1, whereas

$$P(h_2) \leq P(h_2, e).$$

so that the evidence supports h_2, yet

$$P(h_1, e) \geq P(h_2, e).$$

Hence, h_2 is supported by the evidence yet is less probable than h_1, which is undermined by the evidence.

This elaborate proof is superfluous, as is the model for it. It is merely a tedious if striking application of the point made by Popper in 1935 and since then generally received: probability is the inverse of informative content and science is the search for content; hence, science is not a search for probability.[35]

The more serious criticism of the identification of confirmation with probability is directed at the identification of probability with distributions. The probability of a hypothesis concerning a distribution cannot possibly be the same as the distribution it depicts, since we have competing hypotheses concerning a given distribution, and the sum of their probabilities is a fraction, but they can each ascribe a high distribution so that the sum of their distributions will exceed unity. Attempting to escape this criticism one may seek refuge in the preference for equi-distribution. This lands one in the classical paradoxes of probability. Attempting to escape this criticism one may seek refuge in the preference for confirmed distributions. This not only begs the question: it raises the paradox of perfect evidence: the evidence that fits a given distribution perfectly both raises its probability and keeps it intact—which is absurd.

How can one go on examining the defunct option that science equals probability? Only on the supposition that science is a success story and the public-relations spokespeople of science are convinced that the

difficulties piled on their road to present science as a success story are marginal.

Is science a success story? Decidedly yes. What kind of success story? It is hard to specify exactly in all detail, but the first details are clear: science is a success story in that it needs no public-relations spokespeople and it is a success story not in their (vulgar) sense of the word.

SCIENCE IS MORE THAN SCIENTIFIC TECHNOLOGY

The vulgar view of science as success is the view of the scientist as a person with a powerful insight, a sort of a magician. Surprisingly, this view does not conflict with the view of science as esoteric, since it alleges that only scientific research is esoteric, not the fruits of science, which are for all to see. The idea that scientific research is somewhat mysterious does conflict with the inductivist idea that research, too, is open to all. This is the idea that science is open to a simple algorithm that can be mastered by everybody. This view of science is dismissed by Popper derisively as the idea of 'science-making sausage machine'. Under the influence of Einstein it is now generally rejected as too simplistic—by all except some zealous adherents to the original idea of artificial intelligence. Today, there is a vast and exciting literature on techniques to aid the process of developing ideas that may lead to discovery ('heuristic', is the Greek word for this, which was coined by William Whewell, the great nineteenth-century philosopher who was the first to criticize the idea that there can be a science-producing algorithm). (There are examples of supposedly useful heuristic computer programs, but they are far from having been tested in the field and, anyway, heuristic is the very opposite of an algorithm proper.)[36]

The idea of a science-producing algorithm proper was recently replaced by, or rather modified as, the idea of normal science, so-called, developed around 1960 by Thomas S.Kuhn. The popularity of his philosophy, if it can be called that, rests on his conception of science, normal and exceptional. The exceptional scientist is the leader who prescribes a paradigm, namely a chief example, and a normal scientist solves problems following it. This suggests that the real magic rests in the leadership, the scientific character of the enterprise they lead rests on the obedience of their followers, the normal scientists, and the problems the normal scientists solve are quasi-algorithmically soluble: they are not so simple that a computer or a simple mind can solve, but they are not so difficult as to defy solution.

It is easy to see the allure of this philosophy: it balances a few ideas that seemingly conflict with each other but which share the goodness of being

both popular and useful for the celebrated self-appointed public-relations spokespeople of science; it presents science as assured but not without some expertise and hard work; it assures science its openness to a reasonable degree, so that the public-relations spokespeople of science can see a little of the mystery involved—just enough to advocate it but not enough to partake in it actively.

What is missing in the concoction is the mystery—not the alleged mystery of the leaders of science who cannot and would not divulge the secrets of their craft, but the unmistakable mystery that is the secret of the universe.

It is not that the self-appointed public-relations spokespeople of science are not willing to praise science as the big search; after all they will say anything to glorify it. But they will use the public-relations criteria to judge when it is advisable to praise the search as the intellectual frontier and when to present it in a mundane fashion. Except that they claim to be philosophers, and thus bolster each move with a principle, and thus render complementary compliments into contradictory credentials.

Let us see if this serious matter cannot be approached somewhat more seriously and without the tricks of the trade of the public-relations spokespeople of science.

SCIENCE IS A NATURAL RELIGION

There is so much to do other than gate-keeping. Certain grounds may perhaps be cleared. Certain assertions should be endorsed as a matter of course or clearly dissented from, though, of course, we may also examine them in great detail if we wish. It should be conceded that traditionally science admits as evidence only repeatable evidence, though we may examine this characteristic in great detail if we wish. It should be admitted that traditionally science admits only items open to the general public, though we may examine this characteristic in great detail, too, if we wish. It should be admitted that some of the evidence which science traditionally admits as true is later on deemed false, but not overlooked; rather they are qualified and readjusted. Though we may examine all this in great detail, if we wish, we may want to know right now why these rules are deemed obligatory. The answer to this question is simple: it is taken to be the role of empirical science to explain known facts.[37]

More should be stressed at once: the rules are introduced not as taboos but as reasonable commonsense ideas. It should be clear that one may break any of these rules, but openly and at one's own risk. The

paradigm is Max Planck, who took upon himself a most unusual research project and voluntarily and as much as he could ignored all items that he could not square with it. This was his own private road to quantization.[38]

Past this we are ignorant, and it is advisable to admit ignorance in many areas and open them up for genuine research that may get the philosophy of science out of its recently acquired role as gate-keeper and bouncer and into a proliferation of researches. We do not know how empirical empirical science is, though we have the feel that some technologically oriented researches are much nearer to common experience than some speculative studies of first principles. We do not know how a research report is judged scientific and/or deserving of publication. We know that some erroneous criteria are used, and that much latitude is exercised in the matter; but more information is needed and more deliberation and experimentation.[39] We do not know how much of science is empirical and how much is guided by general principles, by the culture at large and even by politics—international, national or of the local chapter of a scientific society or the local department in the university.[40] We simply do not know enough about how science intertwines with other activities, and we only have an inkling as to what is the minimum requirement for a society that wishes to allow it to flourish, namely, freedom of speech and of dissent and of criticism and of organization to that effect.

It is hard to say what other item, if any, is generally admitted as a basic tradition.

This invites one to scout beyond the current horizon, and seek in the past some heuristic that might be helpful. And the point to start with should, perhaps, be the roots of the unbecoming hostility to metaphysics and to religion that is so characteristic of contemporary philosophy of science that induces its practitioners to undertake the lowly task of bouncers-with-a-sense-of-mission. The rise of modern science is the starting point, as the heritage from that noble period is in great need for revision.

Here, only one aspect of that period will be mentioned, the idea of natural religion. It is the idea that religion comprises a doctrine plus a ritual, that the doctrine is either revealed or natural to all thinking humans as such, and that ritual is prescribed in accord with doctrine. All of these items are nowadays known to be false, but let us overlook this for a while.

The idea of natural religion was that it is supplemented by revealed religion, not inconsistent with it. This cannot be admitted without some qualification on the religion under discussion, but here no specific religion is discussed.[41] The idea of natural religious doctrine, natural theology or rational theology, so-called, is the proof of the existence of

God. This proof is now dead. The idea of the natural or rational ritual is the idea of research as worship. This idea has a tremendous attraction to some researchers, including Einstein, and other researchers consider it silly. The main obstacle in this matter is not the item under consideration, but the idea of religion as belief. The involvement of belief as a central item in any religion is a very strong item of all Western religions—not of all Eastern ones. It also led to the idea that superstitions are prejudices, namely beliefs in ideas that are objectionable or at least not warranted. It is well-known that superstitious people are sceptical, not dogmatic as the philosophers of science describe them, though, of course, what they particularly lack is the ability to be critically minded about their guiding ideas.[42]

Traditional philosophy of science took it for granted that the dogmatic and the superstitious share the errors of clinging to erroneous metaphysical systems, now better known as intellectual frameworks. It recommended not to endorse any unless it is proven. Then Kant proved that a proven intellectual framework is a set of synthetic propositions a priori proven. Then Russell and Einstein between them proved that such propositions do not exist, and the gate-keepers decided to oust all intellectual frameworks. These were reintroduced by social anthropologists and by the posthumous writings of Ludwig Wittgenstein, who spoke of them, somewhat enigmatically, as of 'forms of life'. As far as science is concerned, they were discovered by various historians of science of the Koyré school, and were then sanctified by those who identified them with Kuhnian paradigms. This is a gross error, of course, since the whole point of Kuhn's idea of the scientific paradigms is to prevent the conflict between the diverse scientific systems, especially the classical Newtonian and the modern. To use the jargon expression, he insists that paradigms are incommensurable. (They can be compared, he stresses, but not contrasted.) The whole confusion, and the bouncing that goes with it, will be cleared once we notice that intellectual frameworks do compete, and that science may both use some of them and be used as arguments for and against some of them.[43]

Obviously, a researcher may consciously and clearly follow two different guiding ideas, employ competing intellectual frameworks—from not knowing which of them is true. Taking notice of this simple, commonsense fact will free the theory of scientific research from its obsession with rational belief.[44] Current philosophy of science is fixated on the study of rational belief without any criticism of traditional ideas of belief in general and of scientific or rational belief in particular. The source of this idea was Sir Francis Bacon's superbly intelligent and highly influential doctrine of prejudice: the prejudiced cannot be productive researchers, since theories colour the way facts are observed, so that facts

cease to act as refutations and as correctives of views, so that the prejudiced are blinded to contrary evidence and can only perpetrate their prejudices by endlessly multiplying evidence in their favour. This theory still animates the pseudo-researches of the self-appointed gate-keepers, even though it is amply refuted.[45] The worst of it is that philosophy of science centres on the problem, what theory deserves acceptance, where acceptance means credence. Yet it is well known that we are unable to control our credence, certainly not to confine it to a simple algorithm. It is here that the roots of the erroneous view of science as a competitor of religion can be found and corrected. This is not to deny that scientific research can be a thoroughly religious affair, a dedication to the search of the secret of the universe. This is not to deny that the religious aspect of research is not obligatory either.

Once this is realized, the avenue is open to the study of science as a central item in our culture and to see the interaction of other items in our culture with science. It is interesting to view the philosophy of science as part-and-parcel of our culture rather than as an isolated item in philosophy. What isolates the philosophy of science from the philosophy of human culture in general is the idea of the gate-keepers that any item not quite scientific is beneath the dignity of the philosopher. This idea is not quite philosophical. Nothing human is alien to any philosopher—of science or of any other aspect of human culture.

NOTES

5 For this task of sifting the grain from the chaff in the claims of the ecological and the peace movements, see my *Technology: Philosophical and Social Aspects,* Dordrecht, London and Boston, Kluwer, 1985.

6 For more details see my 'The Functions of Intellectual Rubbish', *Research in the Sociology of Knowledge, Science and Art* 2 (1979):209–27.

7 For more details see my 'On Pursuing the Unattainable', in R.S.Cohen and M.W.Wartofsky (eds) *Boston Studies in the Philosophy of Science,* II, Dordrecht, London and Boston, Kluwer, 1974, pp. 249–57; repr. in [7.4].

8 References to Max Born's writings will not convey the definiteness and decisiveness with which he said this as he explained to me his refusal to gratify my request for his help in my struggle with the philosophical problems of quantum theory.

9 See Max Born's review of vol. II of Sir Edmund Whittaker's *A History of the Theories of the Aether and Electricity, The Modern Theories,* 1900–1926

(Edinburgh, Nelson, 1953) in *The British Journal for the Philosophy of Science,* 5 (1953):261–5.

10 In the original 'monkey trial' matters stood quite differently: not dogmatism but obscurantism was at issue, as the contested demand (of the state of Tennessee) was to forbid the teaching of evolutionism in school, not the demand (of a sect) to allow schools to teach creationism. The original defence was run by Clarence Darrow, who would not dream of inviting expert scientists, as his attitude was old-fashioned, as is clear from his autobiography.

A curious example of the use of an expert in science occurred when Faraday introduced his theory of ionization: he introduced a new terminology and this aroused displeasure which he dispelled by reporting that the terminology was suggested by William Whewell. Faraday stressed on that occasion that science is one thing and words are another. See my *Faraday as a Natural Philosopher,* Chicago IL, Chicago University Press, 1971.

11 It was Samuel Butler who asked, at the end of his classic *The Way of All Flesh,* how do we survive the educational system? His answer is tremendously intelligent: he says, we owe the survival of our culture to the imperfections of the educational system. (This explains his attitude to Matthew Arnold, the leading educationist and educational reformer of his age.)

12 For more details see my 'Science in Schools', a discussion note in *Science, Technology and Human Values,* 8 (1983):66–7. As far as I know there was no response to this note of mine, especially not by the expert witness in the Arkansas court, whom I criticized there. That expert obviously relied on his (mis)reading of the works of Karl Popper, which he found necessary to ridicule on other occasions. This, I suppose, exempts him from the charge of dogmatism: the practice of public relations is hardly an expression of a dogma.

13 For more details about cargo cults see I.C.Jarvie, *The Revolution in Anthropology,* London, Routledge, 1964, and other editions.

14 This is questionable, as the reason Maimonides claimed that Moses was a scientist was more in order to boost science than to boost religion. See for more details my 'Reason within the Limits of Religion Alone: the Case of Maimonides', forthcoming.

15 For details and references concerning the controversial status of the works of Claude Levi-Strauss, see my [7.3], ch. 2.

16 Sir Francis Bacon introduced 'the mark of science' (*Novum Organu,* Bk. I, Aph. 124: 'the goal and mark of knowledge which I myself set up'; 'Truth… and utility are here the very same thing'; see also his *Works,* 1857–74, 3, 232: 'I found that those who sought knowledge for itself, and not for benefit or ostentation or any practical enablement…have nevertheless propounded to themselves the wrong mark, namely satisfaction (which men call truth) and not operation.' Unfortunately this was often read as relativist, despite clear antirelativist remarks of Bacon, say, in his *Novum Organum,* Bk. I, Aph. 129 and throughout his writings, from his early manuscript, *Valerius Terminus,* onwards. Yet he clearly said, the mark of science is its success: alchemy promises the philosopher's stone and science proper will deliver the goods.

17 The exception is Popper's criterion of demarcation which is within language rather than of language, so that he could afford the luxury of ascribing scientific status to some theories and not to their negations. For more details

see my 'Ixmann and the Gavagai', *Zeitschrift für allgemeine Wissenschaftstheorie* 19 (1988):104–16.

18 For more details see [7.31].

19 It certainly is important, both theoretically and practically, to find out as best we can, which of the regularities we observe is due to changeable local conditions and which is unalterable. The relativists cannot even pose this question intelligibly. See my *Technology,* (note 5).

20 For all this see Karl Popper, *Objective Knowledge,* Oxford, Clarendon Press, 1972, Ch. 1.

21 There is precious little discussion of these two points, of the openness of science and of the repeatability of scientific experiment, and these are brief, as if to intimate that these matters are both too obvious and non-negotiable. Though they appear originally as one in the writings of Robert Boyle, such as the Preface to his *The Skeptical Chymist,* they usually appear as separate if at all. The attempt to (re)unify them occurs first in Karl Popper, *Logik der Forschung,* Vienna, 1935, and later in the writings of Robert K.Merton.

22 Einstein asked, in his preface to Stillman Drak's translation of Galileo's *Dialogue on the Two World Systems,* why did it matter to Galileo that the Church of Rome rejected Copernicanism? There are two sufficient reasons for that, I think, one that he was an obedient son of that Church, and the other is that science at the time was under attack and had to fight back. This does not constrain, however, the correctness of the distaste towards bouncers that Einstein exhibited in that discussion.

23 Sir John Herschel suggested in the early nineteenth century that scientific evidence is *bona fide*. This is wonderful but no longer valid, as so many court cases testify. For more details see my 'Sir John Herschel's Philosophy of Success', *Historical Studies in the Physical Sciences* 1 (1969):1–36, reprinted in [7.4].

24 This was stressed in Robert Eisler, 'Astrology: The Royal Science of Babylon', which has since gained significance despite its defects from the studies of Derek J. de Solla Price's studies of the import of Babylonian science for the rise of Greek science. See [7.21].

25 See my 'Theoretical Bias in Evidence: A Historical Sketch', *Philosophica,* 31 (1983):7–24.

26 For more details see my 'The Role of the Philosopher Among the Scientists: Nuisance or Necessary?' *Social Epistemology* 4 (1989):297–30 and 319.

27 See for all this my 'Sociologism in Philosophy of Science', *Metaphilosophy* 3 (1972):103–22, reprinted in [7.4].

28 For the difference between criteria of demarcation and touchstones see [7.2].

29 For more details concerning the fact that the contents of some theories but not of all of them are read as a *façon de parler,* see my 'Ontology and Its Discontents' in Paul Weingartner and Georg Dorn (eds) *Studies in Bunge's Treatize,* Amsterdam, Rodopi, 1990, pp. 105–22. (This book appeared also as a special issue of *Poznan Studies,* Vol. 18).

30 For details see my 'The Mystery of the Ravens', *Philosophy of Science,* 33 (1966):395–402, reprinted in my *The Gentle Art of Philosophical Polemics: Selected Reviews,* LaSalle, Ill., Open Court, 1988.

31 The demand that all (relevant) information be considered is a safeguard against prejudice. It does not work, since it permits the refraining from the search for instances to the contrary. In the absence of any background

knowledge, the demand that all competing hypotheses be examined nullifies their initial probabilities, since there are infinitely many hypotheses and the sum of their probabilities is unity. The introduction of any background hypotheses may easily alter this and render the problem very easily soluble. The literature debates the principle of simplicity (John Stuart Mill), otherwise known as the principle of limited variety (John Maynard Keynes), or of the redistribution of initial probabilities (Sir Harold Jeffreys). These do not work, but other hypotheses work very comfortably. For example, analytic chemistry works inductively very nicely against the background of the table of elements—provided its refutations are ignored, and to the extent that this is possible. Nuclear chemistry, of course, requires different background hypothesis.

The amazing thing is that a whole movement in the philosophy of science evolved when a suggestion was made to study the problem not in the abstract but as against given background hypothesis.

32 For all this see my *Technology* (note 5).

33 See my The Mystery of the Ravens' (note 30). In that essay I did not discuss the folly of the requirement that the criterion of confirmation should be formal. It clearly has to do with the theory of demarcation of science by meaning, presented above, which presents science as in principle utterly decidable and the competition as unable to articulate except by either endorsing or rejecting some scientific verdict or another. In brief, it is the idea that a formal criterion makes the life of a bouncer easy. In a public discussion at the end of a session of the Eastern Division of the American Philosophical Association in Boston some years ago, devoted to the contributions of C.G.Hempel to the philosophy of science, I said that researchers do not require licence from the philosopher before they dare employ a metaphysical theory in their researches. To this Hempel answered that at least his theory of confirmation was intended to oust theology, and did so rather well.

34 For the critique here cited see Popper's 'Degree of Confirmation', 1955, reprinted in [7.45], Appendix IX and many later editions.

35 This should be stressed. Popper's point is that informative content (not in the sense of information theory but in Tarski's sense) is the reciprocal of probability. R.Carnap and Y.Bar-Hillel have endorsed it and yet Carnap insisted on the identification of confirmation with probability.

36 For more detail, see my 'Heuristic Computer-Assisted, not Computerized: Comments on Simon's Project', *Journal of Epistemological and Social Studies on Science and Technology* 6 (1992):15–18.

CHAPTER 8

Chance, cause and conduct: probability theory and the explanation of human action

Jeff Coulter

INTRODUCTION

Human actions remain at the core of most serious explanatory work undertaken within the behavioural sciences, but there still remain major obstacles blocking an appreciation of the truly unique status of the phenomena we subsume under this rubric. In particular, an abiding theme in explanatory strategies continues to be the objective of explaining human actions by invoking *probabilistic causality* as an epistemic solution to the problem of the failure of deductive-nomological causal schemata in this domain.[1]

Deductive—nomological explanation takes the form of the logical derivation of a statement depicting the phenomenon to be explained (the *explanandum*) from a set of statements specifying the conditions under which the phenomenon is encountered and the laws of nature applicable to it (the *explanans*). A typical example of such a form of explanation would be: The occurrence of photosynthesis in plants with green leaves is explained by (i) the law which states that sunlight interacting with chlorophyll (the active agent in the leaves) generates complex organic materials including carbohydrates; and (ii) the actual conditions which obtain, viz., the exposure of green leaves to sunlight. The *explanandum* (e.g., an instance of photosynthesis) is thus a conclusion strictly deducible from a set of premisses which state the relevant law(s) and the antecedent condition(s). Despite its limitations as a model for many natural-scientific causal (deterministic) generalisations, this conception of explanation became a model for social-scientific emulation.[2]

Explanatory research in the contemporary human sciences concerning human behaviour rarely employs the terminology of *determinism:* categories such as 'causes' or 'determines' are routinely eschewed or modified in favour of such 'quasi-causal' contenders as: 'shapes', 'affects' or, perhaps the favourite contender, 'influences'. In a widely used text on social research, Earl Babbie observes: 'Most explanatory social research utilizes a *probabilistic* model of causation. *X* may be said to *cause Y* if it is seen to have *some* influence on *Y*.'[3]

Although Babbie is not primarily thinking of human *actions* as explananda here, it is apparent that they are included in the scope of probabilistic-causal reasoning in the behavioural sciences. This conceptual move requires a serious reappraisal. There are many alternative theoretical resources for explaining human conduct which neither require nor employ causal or 'quasi-causal' constructions, and this will be the theme of the closing section of this chapter. However, the continued appeal of 'quasi-causal' models, schemata and theory-building enterprises obscures the relevance and adequacy of *procedural explanation* as an alternative theoretical objective. It is the primary purpose of this discussion to document the *logical* obstacles which prevent explanatory programmatic ambitions in probabilistic clothing from achieving fruition. The prospects for the acceptance of procedural explanation as a (uniquely) appropriate goal for the behavioural sciences clearly depend upon the demonstration of the logical inadequacy of nomological *and* probabilistic approaches to the project of explanation in this domain.

I shall not belabour here the many arguments designed to demonstrate that there are fundamental logical incompatibilities between the grammar of the concepts of human action and the grammar of deductive-nomological (or 'covering law') explanatory propositions.[4] Suffice to say for the purposes of this discussion that very few contemporary theorists and researchers would follow a Homans[5] or a Lundberg[6] in advocating a strictly deductive-nomological programme of enquiry into human social behaviour. The issue I seek to engage in this essay is the idea that a subsidiary form of 'quasi'-causal explanation—a version of what is sometimes called 'weak causality'—can be made intelligible in the explanation of human conduct.

The idea that causation can be conceptualized probabilistically has been the subject of much discussion in the philosophy of the social sciences in recent years. There are two principal positions at stake in the field. Some propose a version of probabilistic causation as an attenuated version of what they consider to constitute 'full-fledged' nomological causation. That is, nomological causation is conceived of as consisting in any contingent relationship between an antecedent event/state-of-affairs and a subsequent event/state-of-affairs which is *invariant* within 'scope

modifiers' (*ceteris paribus* conditions which are determinately circumscribable for most practical purposes), while some probabilists claim that *all* causal connections in nature are species of conditional probabilities such that all 'causes' merely probabilify their effects to a degree that is statistically significant. In what follows, the former point of view will be considered most extensively, since this is the position which has been thought to justify a range of theoretical claims about human conduct in the non-biological human sciences. I shall, however, also make some comments about the latter position.

Hempel argued that there exists a logical alternative to the deductive-nomological (D-N) model of explanation in scientific work, and he referred to this as the 'inductive-statistical' (I-S) model.[7] According to Hempel, we can explain some particular action/event by showing that a statement which predicts it is supported with a high degree of inductive probability by some set of antecedent conditions. The burden of this chapter will be to show that this conception of 'probabilistic explanation' is defective, and that human actions, for reasons to be laid out, are not susceptible to *explanation* by *any* 'probabilistic' account. Before we can appreciate the point of such a demonstration, however, some historical ground must first be covered.

BASIC ASSUMPTIONS IN THE APPLICATION OF PROBABILISTIC ANALYSIS

A central axiom of classical probability theory holds that if any event can occur in X ways and fail to occur in Y ways, where all possible ways are assumed to be equally likely, then the probability of its actual occurrence can be computed according to the formula $X/(X+Y)$ and the probability of its non-occurrence is given by $Y/(X+Y)$.[8] An alternative formulation makes reference to relative frequencies of events defined in advance as successes and failures: the probability of a given event's occurrence (success) is given by *the limit of its relative frequency* approached as the number of trials, samples, draws, etc., increases (approaches infinity). Jakob Bernoulli's golden theorem suggests that the relative frequency of successes continually approaches a stable value as the number of trials (experiments, samples taken, draws made, coins tossed, etc.) increases and that this stable value is equal to the probability of success in a single trial.[9] Bernoulli drew strikingly *deterministic* metaphysical conclusions from the applicability of his theorem:

> If thus all events through all eternity could be repeated, by which we could go from probability to certainty, one would find that everything in the world happens from definite causes and

> according to definite rules, and that we would be forced to assume amongst the most apparently fortuitous things a certain necessity.[10]

This kind of reasoning has come to be known as an 'order from disorder' principle, and it has received modern support of sorts from considerations of the following kind. If you time the decay of the nucleus of a radioactive isotope, it can be determined that its radiation decreases by exactly one half every *N* seconds. For example, thorium C has a 'half-life' (the time it takes for a 50 per cent reduction of its radiation decay) of exactly 60.5 minutes. However, the actual emission of any particular ray/particle by the radioactive isotope is an utterly unpredictable, singular event. It appears that Bernoulli's theorem provides for exactly this sort of determinacy-from-indeterminacy reasoning, and many quantum theorists have projected probabilistic or 'stochastic' attributes to the sub-atomic domain itself as among its 'intrinsic properties'.[11]

The invocation of 'order-from-disorder' reasoning was to play a very significant intellectual role in the social and behavioural sciences. Indeed, Adolphe Quetelet, Durkheim's illustrious nineteenth-century precursor and the founder of 'social physics', sought to argue that while individual social acts (such as committing a crime) cannot be predicted, or perhaps even explained at all, social *regularities* can be detected in rates of crime for a given population. The stability of aggregated statistics, and hence of mean values, encouraged Quetelet to pronounce the possibility of a quantitative social science according to which an abstraction, *l'homme moyen*, or 'the average person', was to figure as the fundamental theoretical concept. As Gigerenzer *et al.* put it:

> Quetelet and his successors believed that large-scale regularities were quite reliable enough to serve as the basis of science. Skilled statisticians would naturally continue to make use of analysis to find how crime or fertility or mortality varied with wealth, occupation, age, marital status, and the like. But even these figures would be averages whose reliability would not grow but decline when the numbers became too small. Quetelet's statistical approach was the purest form of positivism, requiring no knowledge of actual causes, but only the identification of regularities and, if possible, their antecedents. *Such causation was much like the imaginary urn drawings posited by Jakob Bernoulli to model contingent events of all sorts*.[12]

So powerful was the 'order-from-disorderly-events' ontology projected from the tenets of probability theory that James Clerk Maxwell and

Ludwig Boltzmann came to embrace 'statistical laws' in formulating new theoretical foundations for gas physics. Gigerenzer *et al.*, again, document the way in which both Maxwell and Boltzmann 'independently invoked the well-known regularities shown by Buckle and Quetelet to justify their statistical interpretation of the gas laws'.[13] Francis Galton was also employing 'normal curve' conceptions derived from Quetelet. 'Both Galton and the gas theorists also derived their use of the astronomer's error law, or normal curve, indirectly from Quetelet. This is a striking instance of the importance of social science for the natural sciences.'[14] For the *social* sciences, however, it was to be Emile Durkheim who most forcefully propounded a conception of social causation of individual human actions on the basis of Quetelet's achievements.[15] Durkheim's *Suicide* (1897) was to become the *locus classicus* of a newly-forming statistical social science—sociology. The Durkheimian model for sociological explanation exemplified in that work became so influential that even Auguste Comte's contribution was rapidly eclipsed as a resource for the actual conduct of sociological enquiry. Comte had been the actual founder of 'sociology' whose opposition to statistical reasoning had led him to abandon the earlier nomenclature which he had shared with Quetelet ('social physics'), but it was Durkheim and his successors (especially in the United States) who were to assume the mantle of a 'scientific sociology'.

While it is true that Quetelet's 'moral statistics' and 'social physics' played a major role in the formation of the idea that social conditions predetermine differential rates of human actions, and that Durkheim's work on suicide clearly embodied such reasoning, Durkheim distanced himself from Quetelet's assumption of the intervening variable of *l'homme moyen*.[16] None the less, he elevated to the status of a new paradigm of enquiry the precept of 'order-from-disorder' by repudiating individual-level explanations of suicide (e.g., suicidees' reasons as available in, e.g., suicide notes and/or other pre-suicidal communications, or within the terms of some purely 'psychological' theory) in favour of an approach to explaining the *rates* of suicide in given populations, rates which Quetelet and others had determined to exhibit certain regularities.

An important question in interpreting the specifically Durkheimian appeal to the 'order-from-disorder' principle—the claim that macro-level regularities emerge from micro-level unpredictabilities—has been that of whether or not we must construe his resulting explanatory propositions about suicide rates to be *causal* in form. From Durkheim's writings, especially his *Rules of Sociological Method* (1895), it was clear that what he sought were nomological—causal—laws of social behaviour. In *Suicide,* there are references to the necessity of producing 'real laws…[the better to demonstrate] the possibility of sociology',[17] and elsewhere in that text we

encounter frequent allusions to 'social causes', 'real, living active forces' and even 'suicidogenic currents'.[18] However, many commentators select as his central explanatory proposition the following: 'Suicide varies inversely with the degree of [social] integration of the social groups of which the individual forms a part.'[19] Indeed, in a paper written in 1948, the influential American sociologist Robert Merton sought to codify Durkheim's sociological explanation in a classical deductive-nomological format.[20] Others followed this lead.

Although much has been made (and rightly) of Durkheim's neglect of the role of coroners' judgments and the decisions of other public officials in the 'construction' of a statistical rate of suicides,[21] and of his occasional tendency to commit the 'ecological fallacy' of inferring individual-level causation from aggregated data,[22] the more fundamental question of the logical status of any such 'sociological law' of human action has less often attracted the same intensity of critical attention. The fundamental equivocality of Durkheim's formulation has been masked by invocations of what has come to be known as 'probabilistic causality', and this is espoused as a more reasonable/attainable objective for the social sciences than nomological explanation.

Recall Durkheim's major theoretical proposition: suicide varies inversely with the degree of integration of the social groups of which an individual forms a part. From here it is concluded that, for example, anomie (lack of social integration) is a causal factor in explaining suicides. Irrespective of the purely empirical and methodological questions of data selection and interpretation, what could this proposition *mean?* As noted, Durkheim and many subsequent interpreters conceived of it as akin to what we would characterize today as a 'deductive—nomological' explanation, some even comparing it to the laws of thermodynamics, but it clearly cannot satisfy the rigorous prerequisites of a *causal* law. As it stands, it states what amounts to a relationship of co-variation: Durkheim did not have access to the modern statistical tool of the correlation coefficient,[23] but even if he had possessed such a tool and had been able to compute, say, a Pearson *r* from his data, the gulf which logically separates correlation from causation still looms large.

In recent years, then, a kind of 'fall-back' position has been developed within the social and behavioural sciences to cover Durkheim's and much contemporary macro-level explanatory work of a statistical type, whatever the precise statistical tool in use. This is the conception of 'probabilistic causation'. The use of this theoretical construct is supposed to achieve several objectives. First, and most importantly, it is claimed to preserve the *explanatory point* of behavioural research. Second, it is supposed to facilitate a symmetry of explanation and prediction, construed as an especially strong form of theoretical

objective already widely achieved in the natural sciences. Third, it relaxes the demands made by the pursuit of deductive-nomological explanation, the only other form of explanation which carries predictive power. Fourth, it preserves the sanctity (and supremacy) of statistical methods of investigation, of quantitative modes of data gathering and presentation, within the behavioural sciences. Fifth, it makes an appeal to what it construes as cognate forms of explanation elsewhere in the sciences, especially in micro-physics, epidemiology and biomedical science.

In considering the claims made on behalf of the conception of 'probabilistic causality', then, much is at stake. In what follows, a detailed exploration of the logical problems attendant upon the use of 'probabilistic causality', as either a goal or a claim, will be undertaken.

THE INDUCTIVE-STATISTICAL APPROACH TO THE EXPLANATION OF HUMAN ACTIONS

Keat and Urry, in their well-known work, *Social Theory as Science*,[24] point out several obstacles to a full-fledged *explanatory* role for probabilistic statements in relation to events. They observe that, according to Hempel's conception of inductive-statistical explanation, one can:

> explain some particular event by showing that a statement describing it is supported with a high degree of inductive probability by a set of premisses, at least one of which is a statement of the statistical probability that an event of one kind will be followed by, or associated with, an event of another kind.[25]

Drawing upon a discussion of this issue by Donagan,[26] they argue that such an account conflates the distinction between what it is to have a *reasonable expectation* that an event *E* will occur and what it is to have *an explanation* for event *E*. Suppose, they suggest, that we are drawing a marble from an urn that contains a thousand marbles, one of which is black and the rest are white. We draw a white one, and then try to 'explain' this event by reference to the high inductive probability of so doing (p=0.999). As Donagan remarks, however, reasonable expectations differ fundamentally from explanations:

> It is more reasonable to expect at the first attempt to toss heads with a coin than to win at roulette on a given number; but the grounds why it is more reasonable do not *explain* why you succeeded in tossing heads and failed to win at roulette. After all,

> you might have won at roulette and tossed tails. *With respect to explanation,* chance situations where the odds are equal do not differ from those where the odds are fifty to one or a thousand to one.[27]

Any actual *explanation* of the drawing of the white marble from the urn in our example will have to include such considerations as the spatial distribution of the marbles in the urn *vis-à-vis* the angle of trajectory of the fingers of the one seeking to make a draw, the degree of friction of fingers in relation to marbles with respect to the possibility of grasping any given marble, and so on, none of which is given in the probabilistic analysis of the draw. Hempel had assumed that there is a symmetry between the capacity to predict an event and the capacity to *explain* that event. This example shows that the relationship *cannot* be symmetrical, since while a prediction may be forthcoming, explanation is not yet in sight. Notice, in all of this, that the *explanandum* is an *event*—the selection of a white marble. Are human actions properly conceived of, for purposes of explanation, as events? Was the 'selection of a white marble' an action or an event? This will be an issue to which we shall return further on. For the moment, though, I shall focus upon a somewhat different although related conception of 'probabilistic explanation'.

Many commentators have compared, *inter alia,* Durkheim's explanatory proposition about suicide, that anomie is a cause of suicide, to what they conceive of as a comparable one from medical science, that smoking cigarettes is a cause of lung cancer. This comparison is made because in both cases something 'short of a nomological law appears to be at issue. Lung cancers can occur in cases when the victim has never smoked a cigarette in his/her life, and some heavy cigarette smokers fail to contract lung cancer in their natural lifetimes.[28] Similarly, some very 'highly socially integrated' people (by reasonable measures) have committed suicide and some exceptionally anomically situated folk have died purely of natural causes. Cases can be ramified: throughout modern criminology, educational psychology, family sociology, psychopathology and related disciplines, one encounters propositions purporting to explain specific forms of human conduct in terms which fall short of lawfulness but which are still displayed as having explanatory power. The device frequently employed is to invoke probabilistic causality. A transition is made from a statement such as: Under conditions C_1…n, there is a probability of *O.N* that persons *P* will engage in action/activity *A,* to one such as: Conditions C_1…n cause persons *P* to engage in action/activity *A* with a probability of *O.N.* Or, if the conditional probability *p* (X/Y) is significant on the basis of a sufficiently large number of cases of *x*-type events, given *y*-type conditions, then *Y* is causally implicated in the

production of *X*. (Whether specific probability values are actually computed is a separate issue). A standard way of 'interpreting' multiple-regressions or path-analytic models is to extrapolate a 'probabilistic causal' statement of the form: a person's educational level of attainment is a (determinate) probabilistic-causal function of father's educational level, family income, etc., through a range of 'variables'. 'Educability' is assumed to be, thereby, an *equipossible* property. Rom Harré made a very important but often neglected comment upon the problems raised in trying to justify such a theoretical transition from a probability frequency to an explanatory proposition:

> It has long been pointed out (though the phenomenon has only recently been named) that statistical generalizations can lead to two distinct conclusions. For instance, if it is known that 80 per cent of a population have developed property A in certain circumstances and that 20 per cent have not, this can imply:
>
> 1 the probability law that every individual is 0.8 likely to develop the property A in the circumstances; or
> 2 the two non-probabilistic laws that every individual of the domain A determinatively develops A, while every individual of the domain B determinatively develops some property which excludes A, or perhaps no determinate at all of the determinable over A.[29]

Harré's argument proceeds to note that case (1) involves properties which are said to be *distributively reliable*. This means that the propensity to develop the property A can be attributed as an objective property to every member of the original domain. 'The probabilistic distribution is explained as an effect of individual fluctuation.'[30] Adopting this approach presupposes that *'every member of the domain has A amongst its repertoire of possible properties'*.[31] By contrast, case (2) involves properties that are *distributively unreliable*. *'Frequency cannot be automatically transformed into an individual propensity.'*[32] Statistical frequency is to be understood as a measure of the relative size of two or more domains in each of which the mode of manifestation of the property/properties under study is determinate. If a specific property is distributively unreliable, then 'individuals in that domain might not have that property in their repertoire of *possible* properties'.[33]

Now let us reconsider Durkheim's suicide example (although it is to be understood here that *many* other human actions might be equally considered in this context, such as, for example, raping, murdering, behaving 'schizophrenically', selecting occupation *O*, asking for a divorce, studying successfully, etc.). Is the capacity to 'commit suicide' a

distributively reliable property of persons in any sampling domain? Since probabilities presuppose possibilities, the question may be recast as: is the *possibility of committing suicide* equally distributed throughout any given sampled population? How could *that* be determined a priori? To vary the case for a moment in order to get a better perspective on its significance, is it true, as some radical feminist theorists have argued, that it is possible for *any* adult male of reasonable physiological fitness to rape a female? Is that *possibility* equally distributed throughout a population of physiologically capable males?[34] Is 'physiological capacity' itself a sufficient indicator of the existence of the 'capacity to rape' as a part of adult males' repertoire of *possible* properties? Would 'moral values' have to be added in? And what about educational level? How could they be weighted? Remember that we are not yet dealing with probabilities, but with possibilities. The point here is surely that such a 'possible property' (i.e., the capacity to commit rape or to commit suicide) cannot be *determined empirically* in advance *either way*. It cannot be determined that such possibilities are equally distributed in any population by any method. *A priori* specifications of *possibilities* undergird *any* meaningful application of probabilistic reasoning, especially the derivation of probabilities for individual events. Thus, as far as the applicability of probabilistic reasoning to human behaviour is concerned, we confront a problem here which does not arise in those much more familiar cases in which prior possibilities *can* be determined empirically; for example, the number of sides of a coin, the number of marbles in the urn, the physically possible outcomes of a critical experiment, etc. The assumption that, for example, the capacity to commit suicide under some conditions is equipossible, is non-demonstrable, and thus a central requirement for the derivation of a determinate conclusion from the application of probabilistic reasoning to a sample of such cases is not satisfied *and not satisfiable*.

Although, as Pollock has remarked, '[i]t is generally recognised that existing theories of probability do not provide us with an account of a kind of probability adequate for the formulation of probabilistic laws',[35] none the less some philosophers continue to pursue such a theoretical formulation. One interesting theme has been to reformulate *causality* itself in wholly probabilistic terms, thereby denying that causal laws are ever genuinely specifiable as invariances within scope modifiers. Instead, 'the idea is that a cause should raise the probability of the effect; or in other words, that an instance of the type taken to be the cause should increase the probability that an instance of the effect type will occur.'[36] A problem with any such formulation is that the concepts of 'cause' and 'causal' (as well as 'effect') are not given any independent specification apart from their putative 'probability-raising' function. The analysis thus tends to assume what it needs to demonstrate, namely

that the meaning of 'cause' is wholly explicable within the language of probability theory without illegitimate conflation with other, well-established probabilistic concepts and without circularity. What is also being assumed is the *invariant* inapplicability of the concept of 'certainty' to *all* causal propositions, an assumption which places a strange restriction upon our use of the word.[37]

Wittgenstein's exploration of the logical grammar of the concepts of 'certain' and 'certainty' is usually ignored in this context.[38] However, a serious problem confronting efforts to analyse all lawful, causal relationships into stochastic ones involves the presupposition of a causal field about which one may be 'certain' in the sense that 'doubt' is *logically* excluded. For example, the proposition that the probability value of getting heads in one toss of a coin is 0.5 itself depends upon the indubitability (certainty) of the causal effects of the gravitational field as a component of the conditions within which any such toss is to be made (or envisaged, to cover the possible-worlds extension of the case in point). To use a Wittgensteinian argument, one cannot treat as hypothetical, as subject to doubt, as *merely probable, every* facet of a system or field of operations within which a probability is being estimated.[39] Thus, *some* causal relationships must be assumed as beyond doubt, as not themselves susceptible to merely probabilistic formulation: attempts to characterise *all* causal relations in probabilistic terms, therefore, subvert the very possibility of establishing a stable domain within which any *particular* probability can be computed.

HUMAN ACTIONS AND NATURAL EVENTS

The abiding assumption of almost all of the work in the field which employs probabilistic concepts in the context of formulating theoretical explanations of human conduct is the equation of 'human action' with 'event'. It will be remembered that probability theory was formed as a device (or array of devices) for facilitating predictions—of events, outcomes, consequences, successes/failures, states of affairs, etc., with numerical indices informing our degree of confidence, level of (legitimate) expectation, etc. Its extension in the service of ruling out *null hypotheses* or 'chance set-ups' by Fisher and his successors in the conduct of agricultural and subsequent modes of experimentation still rested upon the deployment of the concept of 'expectation'. Explanation, itself, was to be a subsequent matter of interpreting the results, using the alternative-to-null hypothesis, given an achieved 'significance level' (expressing the probability that the outcome occurred 'by chance' or not).[40] However, the

appeal to 'probabilistic causation' has encouraged behavioural scientists to conceptualise human actions of various kinds as *in principle* amenable to treatment as 'events' or 'occurrences' to which the concept of 'chance' (and 'chance distribution') might be a priori applicable.

The idea that someone *did* something 'by chance' is often confused with the ordinary notion of someone *achieving* something in, through or by their action (some (unintended) outcome, result, transformation, upshot, effect, consequence etc.)[41] 'by chance'. The intelligible claim that people can do some particular sort of thing *arbitrarily* is, in turn, sometimes confused with the notion that people who have behaved arbitrarily in some sense have thereby behaved *randomly*. However, even the 'random murder' committed by the psychopath is scarcely comparable to the random emission of a particle by an isotope: the probabilistic concept of 'randomness' does not fully reduce to that of 'arbitrariness',[42] any more than the concept of a human action reduces to that of an event in nature.

An event is something that *happens* (sometimes *to* someone), whereas an action is something that someone *does*.[43] Events do not have motives or intentions, whilst actions (routinely) do: events occurring in nature, independently of human agency, are not governed by social rules, norms, conventions or stipulations, whereas most of the actions of human agents are.[44] Zeno Vendler has observed that 'the breaking of the window' may be *either* simply an event description (amenable to a causal explanation) *or* a description of something that someone did. What decides the matter is whether the case being described is one in which the window breaks or one in which someone breaks the window. Compare this case with one such as 'the walking of the dog' in which the potential event/doing ambiguity can be brought out more sharply: either the dog was walking (intransitive) or someone was walking him (transitive). Vendler comments that some verbs exhibit a morphological transformation in the verb root which marks the purely transitive occurrence (e.g., rise-raise, fall-fell, lie-lay), and he concludes that 'the rising of the flag is not the same thing as the raising of the flag, the falling of the tree is a different thing from the felling of the tree'.[45] The falling of the tree may have been (probabilistically) predicted, or even given a causal explanation, but my felling of the tree is to be explained in wholly other terms.

Now let us reconsider the earlier case of 'selecting a white marble'. This can, as it stands, be construed in at least two ways: either the agent intentionally selected a white marble, or he selected a marble 'blindly' and it turned out to be a white one. It is clearly the latter case alone which is the relevant case for a probabilistic analysis. The former case may properly be considered, *in its entirety*, to be an (intentional) action. The latter case, however, differs significantly (grammatically) from it.

There, the agent's *action* may be described as, for example, making a random selection. The *outcome* of this action (and it is *this* which is the exclusive target of the probabilistic analysis) was that *a white marble was drawn*. The *event* is the *outcome,* and this is detachable, for the purposes of the analysis of reasonable expectation, from the agent's action. After all, one could say that whether or not the outcome of the act of selecting had been a white *or* a black marble, i.e., if the (target) *events* had differed, the same act of 'randomly selecting' had been performed. While the universe of possible event outcomes may be determinable in advance, the universe of possible actions cannot be. This is not because there is an *infinite* number of possible actions which human beings can perform or undertake: rather, it is because the number of possible human actions is *indefinite:* there is no *closed set* whose elements contain every possible human action, and no set containing as elements every situatedly possible option, even though there are *preferred* options, *rule-ordered* options, and the like. The magician who requests of an audience-member that he 'select a card from the pack' cannot *determine the possibility* of his or her compliance to his request in advance in the way in which he could determine the domain of outcome possibilities (and hence the probability of *any* particular outcome as 1/52).

Because there *are* patterns, regularities, orderlinesses, in human conduct (over and above the mechanistically analyseable *biological* processes subserving such conduct, though not identical to it), the failure of nomological explanation in the social and behavioural sciences has been compensated for by invoking probabilistic causation: but the alternatives are not restricted to 'cause' or 'chance'. The actions in which people engage are differentially amenable to characterisation in terms of a very large set of assessment options in respect of their contingencies of production. A given action of a specific sort may be undertaken as a matter of rule, convention, habit, obligation, preference, disposition, coercion, spontaneity or caprice, among many other contextually relevant dimensions. There are many gross and subtle distinctions to be observed between these characterizations, and even caprice and spontaneity will not reduce to 'pure chance' nor coercion to strict nomological causality. One's expectations may be raised about the prospect of someone's doing something if it can be said of him that he 'is liable to' do such-and-such as distinct from merely 'tends to' or even 'is disposed to' do it, but such a raising of one's expectations hardly qualifies for analysis in terms of a calculus of probabilities.

STATISTICAL METHODS PRESUPPOSING CAUSALITY DO NOT DEMONSTRATE IT

There are many critical treatments of the application of statistical methods of analysis and explanation in the non-biological human sciences, and it is not the purpose of this essay to review these arguments. Most of them focus upon the problems involved in relating the demands or assumptive requirements of statistical analysis to the actual 'data' or empirical observations and their conceptualizations provided by researchers,[46] or upon the vexed question of the *relevance to agents* of correctly identified 'variables'.[47] These are deep issues, but proponents of quantitative inquiries in the behavioural sciences have become accustomed to treat them as technical ones, assuming that the fundamental logical appropriateness of statistical inference in the domain of explaining human behaviour emerges unscathed.

The transition from the original loci of inferential-statistical applications to their modern fields of use is sometimes treated as a process of successful intellectual cross-fertilization. The 'fertilization' metaphor is apt: some of Fisher's most important work was undertaken 'in the context of the practical demands of agricultural research'.[48] Indeed, genetics and agriculture were the two chief domains for the development and application of mathematical statistical theory in the early twentieth century. Francis Galton and Karl Pearson were primarily concerned with the analysis of genetic inheritance.[49] The founder of 'path analysis', Sewell Wright, was concerned with problems of population genetics. Biological and medical applications became increasingly common, and immensely productive, but it was through the transposition of inferential-statistical analysis to problems in psychology that the first link with the study of human conduct was established.[50]

In the domains for which inferential statistics had been developed and employed, 'causality' and 'chance' were two epistemic axes for thinking about event *explananda*. During the transposition to the study of human behaviour, these epistemic axes or presuppositions were preserved intact, just as, earlier, with classical mechanics as the model for emulation, a search for 'laws' had been the primary explanatory objective in the behavioural sciences. B.F.Skinner, for example, reacted negatively to the introduction of inferential statistics into psychological methodology, insisting upon the formulation of 'functional laws' governing organism-environment transactions as the proper goal for experimental psychological research. Rapidly, however, one inferential-statistical technique, *the analysis of variance,* rose to prominence as perhaps the most widely used of the battery of methodological devices in the behavioural sciences.

The deployment of the 'analysis-of-variance' (ANOVA) technique is

designed to show whether or not a 'null hypothesis' about the *effect* of some 'treatment' variable (e.g., a pre-specified level of alcohol consumption) *upon* some 'statistical population' (e.g., a set of scores of measured reaction times) should be *rejected*. This depends upon the satisfaction of a range of assumptions, including the possibility of conducting a rigorous experiment in which the variables under study can be manipulated; the assumption of a 'normal' distribution (bell-shaped distribution) of trial scores were there an infinite number of such experiments conducted, and the assumption of 'variance homogeneity', i.e., the assumption that each set of scores has the same variance or 'dispersion about the mean'. To test the null hypothesis (e.g., that the given level of alcohol consumption has no effect upon reaction times), we compute two estimates of score variance, one of which is independent of the truth or falsity of the null hypothesis while the other is dependent upon it. If the two estimates concur, then we have no reason for rejecting the null hypothesis, whereas if they disagree, we may reject the null hypothesis and are entitled to infer a *causal contribution from the underlying 'treatment differences'* (e.g., the level of alcohol consumption) to our second estimate.

Reaction-time studies were among the earliest to be conducted using the ANOVA technique. However, they posed few epistemological difficulties: the effect of a given fertilizer upon a given crop yield is a problem with a sufficiently similar conceptual structure to the problem of the effect of a given level of human alcohol consumption upon reaction times as measures of alertness. It is when human *actions* are the explicit *or, more commonly, implicit,* focus of explanatory attention that problems arise. Many explananda in the behavioural sciences are thought to comprise discrete *states* or measurable *properties* of persons whereas in fact they comprise arrays of *human actions and their socially ascribed adverbial qualifiers* (often with only 'family resemblances' between them). This shows itself most forcefully in the area of studies of human intelligence.[51]

Considering the claim that differences in 'IQ' ('measured intelligence quotient') are caused by genetic differences,[52] a typical interpretation of the results of some ANOVA studies of this presumed relationship, Alan Garfinkel has argued that special consequences, often overlooked, ensue from the fact that the concept of 'heritability' being used is a statistical one.

> The heritability of a trait in a population is defined as the amount of variation in that trait which is due to genetic variation. The trouble with this definition is that it uses the concept 'due to', a causal concept. This causality is analyzed away statistically by talking instead about correlations between

> genetic variation, on the one hand, and variation in the trait, on the other.[53]

What Garfinkel characterizes as the 'slide into correlationism' is problematic here: in the case of a society which discriminates against red-haired people, poverty has a high 'heritability' because it is highly correlated with a genetic trait, red hair:

> But this is obviously misleading. Intuitively, there are two distinct types of situation: on the one hand, the situation where there really is some genetic cause of poverty, and on the other, the type above, where the cause of poverty is social discrimination. *By its nature the concept of heritability cannot distinguish between the two.* Since it is a correlational notion, it cannot distinguish between two different causal configurations underlying the same covariance of the genetic trait and the social property.[54]

'Intelligence' would seem to be a concept of an *intrinsic* property, closer perhaps to 'having red hair' than to 'being poor' on a scale of biological-to-sociological attributes. Granting Garfmkel's point about the suppression of 'the true causalities which underlie these correlations' by the invocation of ANOVA studies of 'heritability', the question appears to remain: what is the 'true causality' for a given variation in levels of intelligence? The problem, however, is with the phenomenon of 'amount of/level of intelligence' conceptualized as an intrinsic property of a person: this is not just a function of overlooking the tenuous connections between 'intelligence quotients' and 'actual intelligence'; it is a more basic function of overlooking the fact that *any* ascription of 'intelligence' whatsoever, lay *and* 'professional', is predicated upon normative assessments of situated *actions,* their modalities and their consequences. 'Intelligence' decomposes into a variety of *praxiological* phenomena. One's intelligence is not a concrete endowment like one's nervous system. It is that which is attributable to someone who does certain things 'intelligently', or who does 'intelligent things'. Activities performed intelligently are very diverse, but even if we restricted ourselves to those activities performed as constituents of 'IQ tests' (e.g., basic arithmetical calculations, precising/paraphrasing texts, matching words to pictures, etc.), it is clear that one cannot sensibly seek to partition them into biological and cultural 'components' any more than one could determine 'how much' of what a person says is 'due to' his vocal chords and how much is 'due to' his knowledge of the language he speaks. Assuming that 'intelligence' or 'amount of intelligence' are phenomena which *could* be *causally* explained (by genetic, environmental or conjoint genetic-environmental 'factors'), as ANOVA studies routinely do, simply

presupposes the chief point of contention, viz., that *human actions can be causally explained*.

Let us consider more closely the capacity to 'speak intelligently' as a feature of someone's 'intelligence'. In exhibiting this capacity, in saying something 'intelligent' or in 'speaking intelligently', a person can be said to be doing something, engaging in the production of a rule-governed communicative activity (a speech act of a specific sort, or series of such speech acts) with its attendant, ascribable possibilities of evaluation from among which 'intelligently/unintelligently' may be appropriately selected as relevant assessment options. (Contrast this with an action such as 'tying his shoelaces', for which the options 'deftly/clumsily' might apply, but hardly those of 'intelligently/unintelligently': the actions assessable as 'intelligent/unintelligent' are restricted by both natural *and* conventional criteria). To be able to speak in a manner which qualifies for assessment in these terms, the speaker must be saying something in a natural language (or derivative system), and this obviously means that a constitutive component of his behaviour, his grasp of English, for example, is a product of socialization. His range of vocabulary and command of syntactical complexity also are contingent upon the kinds of life experiences in a society to which he has been exposed (e.g., educational opportunities and encouragement, level of educational attainment, distribution of fluent speakers *vis-à-vis* non-fluent ones in his biographical history, their differential impact upon him as models for emulation, etc.). The topic of his discourse must be recognizably of a type which can be assessed in terms of the relevant dimensions ('intelligent/unintelligent') and not be one that is *not* susceptible to the use of such criteria (e.g., coining a quip, as distinct from repeating a joke: developing an argument, as distinct from hurling an insult). Consider these features—vocabulary, syntax, topic (and many related ones)—as 'environmentally derived'. Now consider the following. To be able to speak at all requires a vocal apparatus, a functioning laryngeal system with intact motor functions in the mouth and throat. There is a complex physiological apparatus, extending deep into the cortex, which *facilitates* (but does not cause)[55] the production of normal speech, most of which may be thought of as components of a person's genetic endowment. Consider these features as 'genetically derived '. Now, for any case *or sequence of cases* in which a person can be *interpersonally assessed* as 'speaking intelligently', itself a common (although by no means exclusive or necessary) criterion for 'having intelligence', how is one to proceed to *partition* and *weight* those contributions made by an 'environment' and those made by 'genetic endowment' to the action or sequence of actions so assessed? Remember that, for the purposes of defining 'intelligence', an 'environment' has been argued to include not only the activity (activities) of the target

individual(s) but also the evaluative assessment of others, made against a background of conventional criteria of complex kinds.

'Intelligent discourse' is hardly the sort of 'phenomenon' which can be analysed into discrete 'components' making their 'causal contributions' in a linear, additive manner. Should the amount of variation between people with respect to their 'speaking intelligently' be parcelled out into the amount due to 'genetic' variation (80 per cent? 40 per cent?) and that due to 'environmental' differences (20 per cent? 60 per cent?)? Even now to reconsider the question is to see that its basis is entirely wrong, and the mistake is a function either of failing to appreciate the complexity of human conduct, the varieties and range of human actions with their adverbial potentials, which are glossed by categories such as 'intelligence', *or* of presupposing without question the applicability of causal reasoning to, *inter alia*, rule-governed behaviour. Usually, the one error is committed *pari passu* with the other.

Inferential-statistical studies of the kind known as 'analysis of variance' have been exceptionally illuminating in their domains of proper application, but the extension of this technique into the field of human conduct is fraught with logical difficulties and anomalies which are only obscured by treating human actions as phenomena of the same fundamental logical types as natural events, discrete states, quantifiable differences or fixed or variable properties/attributes.

CONCLUDING REMARKS

The uses (and abuses) of probability theory are many and varied. In this discussion, I have restricted myself to the consideration of some fundamental but interrelated issues which are not often addressed directly by proponents of inferential-statistical analysis as the *sine qua non* of explanatory work in the sciences of human action. Convinced that the conceptual or logical credentials of probabilistic reasoning about human behaviour are impeccable, theorists and researchers alike tend to give much less credence to alternative, non-statistical, approaches to the study of human conduct. It is high time that this unfortunate proclivity were abandoned: the logical foundations of statistical-inferential work in the social sciences are not nearly as impeccable as some of its influential champions would have us believe, and the detailed investigation of the properties, logical and empirical, of *in situ* human conduct which have been conducted over the past twenty or thirty years in more 'qualitative' areas of the behavioural sciences attest to the comparative crudity of the models of behaviour which have been constructed solely to facilitate a preferred methodological strategy of an inferential—statistical sort. Reifications of the kind seen above in

the statistical study of the heritability of 'intelligence' are partly a function of insensitivity to the properties of the praxiological phenomena glossed by such categories and partly a function of the over-extension of techniques such as ANOVA to domains for which it had not originally been developed.

If the arguments presented here are correct, then the project of formulating probabilistic-causal explanations is indeed questionable. The further point could be made that it is largely irrelevant. Explanation is a motley affair: if probabilistic-causal explanation is the poor step-child of nomological explanation, then it is time to look again at the explanatory project and ask: what *sort* of scientific (abstract, general, observationally based) explanations are logically appropriate, methodologically defensible and manageable for the scientific study of the domain of human conduct?

One very important alternative contender for the explanatory stakes these days is *procedural* explanation. Here, the theorist or researcher seeks to develop an empirically grounded characterization of *how* human beings produce whatever forms of conduct they produce, including their behaviour of 'explaining their behaviour', of producing 'reasons-for-their-actions'. The form of scientific explanation here is basically a *grammatical* one. That is, the objective becomes to specify a set of abstract rules, principles, procedures or 'methods' (not necessarily of an *algorithmic* kind) which explain how conduct is (re)produceable in its details, to any desired level of such detail.[56]

Advocating the pursuit of alternative forms of explanation is not an invitation to endlessly 'reflexive' self-examination or 'deconstructive' nihilism: the fundamental goals of any empirical science of human action worth its salt should remain those of illuminating the nature of the phenomena and relating any such insights to relevant areas of interest and significance in the other life sciences. Anything less would be to substitute for the demanding project of truly scientific inquiry the fads and vagaries of an ideological quest.

3 Earl Babbie, *The Practice of Social Research,* 4th edn, California, Wardsworth Publishing Company, 1986, p. 65 (emphasis in original). Babbie also remarks: 'A perfect statistical relationship between two variables is *not* an appropriate criterion for causation in social research. We may say that a causal relationship exists between *X* and *Y,* then, even though *X* is not the *total* cause of *Y*' (Ibid.). The idea that a probabilistic cause is expressible as a fraction (e.g., the idea of something like a 'two-thirds cause' of a given variable) is a

function of extrapolating theoretically from path-analytical models, as we shall see later on.

4 I shall assume, for the purposes of this essay, that Humean-Hempelian causal programmes for the explanation of human actions have been shown to be incapable of coming to terms with many of the constitutive properties of *praxis*. For an early, but still pertinent, treatment of some of the central problems in this area, see [8.31]. Also, see Hanna F.Pitkin's excellent review of the issues in her 'Explanation, Freedom and the Concepts of Social Science', [8.35], ch. 10. Some more recent issues, especially those associated with Putnam, Dennett and Davidson and are discussed in my *Rethinking Cognitive Theory* New York, St Martin's Press, 1983, ch. 1 and 5 and *Mind in Action,* New Jersey, Humanities Press, 1989, ch. 7.

8 This is the 'classical' interpretation associated with the Marquis de LaPlace whose philosophical essay on probability was first published in 1819. For a thorough review of the problems raised by extending the scope of application of the classical interpretation, see W.C.Salmon, *The Foundations of Scientific Inference,* Pittsburgh, University of Pittsburgh Press, 1966. In this chapter, I do not discuss 'subjective' probability. In particular, I shall not be concerned with the assessment of the claim that human agents are crypto-Bayesians. For a good introduction to Bayesian probability, along with some comments on the use of Bayes' theorem as a standard by which to assess 'intuitive probability judgements' made by non-specialists, see Ronald N.Giere, 'Scientific Judgment', ch. 6 of his *Explaining Science: A Cognitive Approach,* Chicago, University of Chicago Press, 1988. For an extensive discussion of the Kahneman-Tversky thesis about putative 'biases' in ordinary human reasoning, informed by the Bayesian model as a criterion, see [8.20] 214–33.

9 The derived binomial theorem holds that the probability of *X* successes in *N* trials is given by: *N* factorial over the product of *X* factorial and *(N–X)* factorial, multiplied by the product of (the probability of a success in any single trial raised to the power of *X*) with (the probability of a failure in any single trial raised to the power of *(N–X)*).

10 Jakob Bernoulli, quoted in F.N.David, *Games, Gods and Gambling,* London, Macmillan, 1962, p. 137.

11 This is the basis of the dispute between the Copenhagen interpretation and its rivals. Some physicists still maintain what could be termed a 'hidden-variable(s)' view of the matter, arguing that the indeterminacies encountered at the sub-atomic level are functions of our current ignorance of forces yet to be discovered which will, once revealed, enable us to reason causally about the phenomena.

27 Ibid., p. 133.

28 A great deal has been made of these 'shortcomings' in the popular debate about smoking and its relationship to lung cancer, but I do not wish to be understood here as giving credence to any kind of *principled* scepticism about the possibility of a strong, causal relation. Even though it is true that the precise *causal mechanism* involved in the generation of cancerous tumours in lung tissue by the nitrites discovered in cigarette smoke has not yet been determined, the claim for a causal relationship of a nomological kind is still a reasonable hypothesis. The problem arises because of the complexity of the scope modifiers required to buttress the strong nomological claim. That lung cancers can occur in the absence of carcinogenic smoke inhalation only shows that this disease can have more than one kind of cause: it does nothing to limit the generalization that smoking causes lung cancer. The problem with the invocation of 'probabilistic causal statements' as 'explanations' in this domain is precisely that it might operate to *foreclose* the search for genuine causal mechanisms and hence for genuine causal-explanatory propositions. This presupposes, of course, that the *domain* within which such a type of explanation is being sought is an appropriate one for such a search. In the case of the smoking/

cancer relationship, all of the evidence points in that direction. This is not always the case, however.

29 Rom Harré, 'Accounts, Actions and Meanings: The Practice of Participatory Psychology' in M.Brenner *et al.* (eds) *The Social Contexts of Method* New York St Martin's Press, 1978, pp. 53–4. It should be noted here that Harré's use of 'law' in the description of the first conclusion carries no causal implication, and the passage might be paraphrased into the generalization: for every individual in the population sampled there is a probability of 0.8 that he/she will develop property A under conditions C, or: there is an 80 per cent chance that he or she will develop property A under conditions C.

38 L.Wittgenstein, *On Certainty,* G.E.M.Anscombe and G.H.von Wright (eds) Oxford, Blackwell, 1969.

39 Ibid. para. 105.

40 There is a long tradition in the behavioural sciences of insisting upon a significance level of at least 0.05 for results derived from the use of the ANOVA technique as a prerequisite for serious consideration and/or publication. For some critical commentaries upon this practice within the social sciences themselves, see, *inter alia,* J.M.Skipper jnr., A.L.Guenther and G.Nass, 'The Sacredness of .05', *The American Sociologist* 2 (1967):16–18 and R.P.Carver, 'The Case Against Statistical Significance Testing', *Harvard Educational Review* 48 (1978):378–99.

41 Part of the difficulty here was noticed by Joel Feinberg who remarked that 'upshots' are sometimes ascribed to persons with the use of singular but complex verbs, such as: 'he frightened him', 'she persuaded you', 'they startled her', etc. This can lead to failures in distinguishing between *actions* and other things 'done' by people. A parallel confusion would be to imagine that 'he slept soundly', being something that he 'did', was an action he undertook. See the treatment of these issues in his 'Action and Responsibility' in Alan R.White (ed.) *The Philosophy of Action,* Oxford, Oxford University Press, 1977. Interestingly, J.L.Austin's categozry of 'perlocutionary *acts*' appears to suffer from such a conflation of act/upshot, or action/consequence.

42 For an event to be 'random' in the terms of probability theory is for it to be *equally as likely to occur* as any other. As Signorile has remarked, 'what we discover at work here is the round-robin of using "random" to arrive at the meaning of equiprobability, and equiprobability to arrive at the meaning of "random"' (Vito Signorile, 'Buridan's Ass: The Statistical Rhetoric of Science and the Problem of Equiprobability' in H.Simon (ed.) *Rhetoric in the Human Sciences,* Newbury Park, California, Sage, 1989, p. 79. Signorile quotes M.G. Kendal and W.R.Buckland (from their

Dictionary of Statistical Terms, New York, Hafner, 1960) as insisting that: 'Ordinary, haphazard or seemingly purposeless choice is generally insufficient to guarantee randomness when carried out by human beings and devices'. And he adds: 'What the statistician is trying to guarantee is strict equality of opportunity. We all know that this just doesn't happen by chance' (Ibid.).

43 Bearing in mind, of course, the *caveats* in the preceding footnote. Of course, on occasion we can speak of someone's doing something as an 'event' (think of one's child's production of his first word, or of the delivery of an historic speech, etc.). However, *these* 'events' have a different logical status from 'events-in-nature'.

44 This point is worth directing against extrapolating from behaviouristic studies of the conditional probabilities of 'responses' given specific stimuli and conditioning histories to the domain of human actions. Most *actions* are not properly construable as 'responses' to *anything,* and, when they *are* so construable, they cannot be specified in properly behaviouristic terms. How could one analyse, for example, the human action of 'answering a question' (which surely would qualify as a sort of 'response') into bio-behavioural event sequences alone? There are no context-free indicators in the stream of speech which alone specify an utterance as an 'answer to a question'.

45 Zeno Vendler, 'Agency and Causation', in Peter A.French *et al.* (eds), *op. cit.,* p. 371. See note 35.

46 An excellent review of the issues raised by dependent/independent-variable analysis, especially the Lazarsfeldian statistical programme in sociology, is provided by Douglas Benson and John A.Hughes in their chapter, 'Method: Evidence and Inference' in [8.13]. For a discussion of a range of issues involved in implementing quantitative strategies of sociological inquiry, especially as they bear upon the problem of data representation, see Stanley Lieberson, *Making It Count,* Berkeley, University of California Press, 1985.

47 On this issue, Herbert Blumer's classic discussion remains unsurpassed: see his 'Sociological Analysis and the "Variable"' in his *Symbolic Interactionism: Perspective and Method,* Englewood Cliffs, NJ, Prentice-Hall, 1967.

48 Donald A.MacKenzie, *Statistics in Britain 1865–1930* Edinburgh, Edinburgh University Press, 1981, p. 211.

49 MacKenzie's outstanding study *(Ibid.)* is a rich source of documentation of the stimuli which powered both the initiatives and the disputes characteristic of the developing field of inferential statistics. Especially interesting is his attempt to relate these directly to the growth of the 'eugenics' ideology of human inheritance and its internal controversies.

50 See Gerd Gigerenzer *et al.,* 'The New Tools' in [8.20], 205–11.

51 I have discussed this issue elsewhere. See my 'Intelligence as a Natural Kind' in *Rethinking Cognitive Theory,* London, Macmillan, and New York, St Martin's Press, 1983 and 'Cognition in an Ethnomethodological Mode' in [8.13], 190–2.

52 It is worth noting at the outset that 'IQ' scores themselves are a function of tests:

> so constructed that the frequency distribution of test scores in the reference population conforms as closely as possible to a normal distribution…centred on the value of 100 and having a half-width or

> standard deviation (the square root of the variance) of 15 points. To call IQ a measure of intelligence conforms neither to ordinary educated usage nor to elementary logic.

(David Layzer, 'Science or Superstition? A Physical Scientist Looks at the I.Q. Controversy' in N.J.Block and Gerald Dworkin (eds) *The I.Q. Controversy,* New York, Pantheon Books, 1976, p. 212)

54 Ibid., pp. 119–20. Emphasis in original.

55 I mean this in the sense in which my having legs enables me to walk, but my having legs does not *cause* me to walk (or run, hop, etc.).

56 For a representative collection of founding papers in the area of social science called 'ethnomethodology', see my edited volume *Ethnomethodological Sociology,* London, Edward Elgar, 1990. Perhaps the most important contributions to this area of enquiry after Harold Garfinkel's originating work have been the studies of Harvey Sacks. See Gail Jefferson (ed.) *Lectures on Conversation by Harvey Sacks,* vols 1 and 2, Oxford Blackwell, 1992. This set is perhaps misnamed, however: Sacks's investigations ranged over modes of human (largely communicative) *praxis* broader than those glossed by the category 'conversation'.

CHAPTER 9

Cybernetics

K.M.Sayre

HISTORICAL BACKGROUND

Cybernetics was inaugurated in the 1940s expressly as a field of interdisciplinary research, in reaction to the specialization that already had begun to encumber the established sciences. Chief among the disciplines initially involved were mathematics (represented by N.Wiener, the leader of the movement), neurophysiology (W.Cannon, A.Rosenbleuth, later W.McCulloch), and control engineering (J.Bigelow). The interdisciplinary base of the group was soon expanded to include mathematical logic (W.H.Pitts), automaton theory (J.von Neumann), psychology (K.Lewin) and socioeconomics (O.Morgenstern). While activities of the group at first were centred around Harvard and MIT, its subsequent expansion led to several meetings at other locations along the northeastern seaboard. Notable among these was a conference on teleology and purpose held in New York in 1942 under the auspices of the Josiah Macy Foundation (followed by other meetings under those auspices resuming in 1946), and a meeting on the design of computing machinery held in Princeton in 1944. The role of these early meetings was like that of a community forum, allowing participants to share insights into common problems and jointly to explore novel means of resolution.

Need for a forum of this sort arose first in connection with problems being studied by Wiener and Bigelow in the design of mechanisms for controlling artillery directed against fast-moving aircraft, which Rosenbleuth saw to be similar to problems he had been studying in the erratic control of goal-directed motor behaviour in human patients. The topic of feedback processes (see below) on which the group subsequently focused attention thus arose from a comparative study of biological and artifactual control systems. Invariably associated with

problems in the design of effective control systems are problems of communicating data to the system on which its corrective responses can be based, and of communicating these responses to the appropriate effector mechanisms. In the biological organism these communication functions are served by the afferent and the efferent nervous systems, respectively, parallel to the radar and the aiming mechanisms of the anti-aircraft battery. This joint emphasis upon communication and control systems accounts for the somewhat inelegant subtitle of Wiener's seminal book: *Cybernetics, or Control and Communication in the Animal and the Machine* ([9.5]).

The name 'cybernetics', chosen by Wiener for this new field of study, derives from the Greek *kubernētēs*, meaning steersman or pilot. Inasmuch as 'governor' derives (via the Latin *gubernare*) from the same root, cybernetics was provided with a ready-made technological ancestry, beginning with James Watt's invention in the late eighteenth century of devices (called 'governors') regulating the rotational speed of steam engines. Political antecedents can be traced back to Plato, who several times in the *Republic* and the *Statesman* likened the leader of a well-run political order to the *kubernētēs* of a ship. A recognizably philosophic lineage also goes back to Plato, with his reference in the *Phaedrus* (247C7–8) to reason as the *kubernētēs* of the soul (prefiguring the Phi Beta Kappa motto *philosophia bion kubernētēs*—'philosophy the guide of life').

Wiener's interest in technical problems of communication had been anticipated by H.Nyquist and R.Hartley, progenitors of the statistical concept of information. Despite Wiener's having numbered C.Shannon among his original group, contributions to this area after publication of the latter's article 'The Mathematical Theory of Communication' ([9.16]) tended to be categorized under the title 'communication theory' (or 'information theory') rather than 'cybernetics'. Another emerging field of research in which cybernetics was initially involved, but soon suffered loss of name-recognition, was the theory of computing machinery. Although Wiener was a key contributor, along with V.Bush (MIT), H.Aiken (Harvard) and J.von Neumann (Princeton), to planning sessions leading to the construction of the first electronic digital computers, he remained more interested in possible neurological parallels with these mechanisms than in their logical design. Subsequent contributions to the field of digital computation owes relatively little to its broadly cybernetic origin.

Cybernetics' early emphasis upon functional parallels between biological and mechanical control systems soon led, in industrial circles, to its identification with factory automation and other forms of robotics. In academic circles, by contrast, cybernetics came to be associated with the then arcane field of artificial intelligence (AI), which took its start as part of an effort to reduce human involvement in the large-scale computer-

based air-defence systems under development at MIT's Lincoln Laboratory in the 1950s. Key contributors to AI at this early stage were O.Selfridge, a younger member of Wiener's original group, along with M.Minsky and S.Papert, all of MIT. Philosophers who became involved with AI through their association with MIT in the 1950s included H.Dreyfus, who was generally critical of the enterprise, and K.Sayre, who saw potential in AI as a new approach to traditional problems in the philosophy of mind. The first institutional centre for combined research in philosophy and AI was established by the latter in the early 1960s at the University of Notre Dame.

Despite its history of involvement with technological developments, the major spokesmen of cybernetics from Wiener onward have been explicitly concerned with its broader philosophic implications. The following discussion treats both its philosophic antecedents and its potential for further philosophic contributions. Remarks on the current interaction between AI and cybernetics are reserved for the final section below.

BASIC CONCEPTS

Philosophy before Plato was marked by a series of attempts to find a small set of basic principles in terms of which the manifest variety of the observable world could be understood as coherently integrated. Cybernetics returns to this task with a set of explanatory concepts based upon the presence of variety itself. Primary among these are the concepts of feedback, of entropy and of information.

Feedback

Any operating system functions within a variable environment with which it interacts through its input and output couplings. Feedback occurs whenever variation at the output works upon the environment in such a fashion as to produce a corresponding variation at the input of the system as well. Of primary concern to cybernetics are two kinds of feedback pertaining specifically to deviation from a stable state of the operating system. Positive feedback occurs when deviation from a stable state produces outputs that lead to yet further deviation. An example is an increase in membership of an interbreeding population which produces an even greater increase in subsequent generations. Feedback of this sort is labelled 'positive' because it tends to increase deviation from stability of the system in which it occurs. Negative feedback occurs, by contrast,

when momentary deviation from a stable state leads to inputs that counteract further deviation. Common examples of negative feedback are the operations of a thermostat to maintain a steady temperature within an enclosure, and the subtle shifts in bodily posture by which a skier maintains balance on a downhill run.

Types of negative feedback may be further differentiated with respect to the bearing of the regulatory mechanisms that maintain a system in a stable mode of operation. Homeostasis is a type of feedback by which deviation from stability is counteracted by adjustments internal to the system itself. Among familiar forms of homeostasis in biological organisms are mechanisms regulating body temperature and chemical composition of the blood. Another type of negative feedback is exemplified by the heat-seeking missile that changes direction with a manoeuvring target, and by the daisy that aims its blossom to catch the full light of the sun. Feedback of this latter sort has been labelled 'heterotelic', for its role in adjusting the system's external relations to factors in its operating environment.

All organic and most mechanical systems incorporate variables that must be restricted to a narrow range of values if the system is to remain operational. A mammal will soon die, for example, if the oxygen content of its blood falls below a certain level, just as a reciprocating engine will soon freeze if it loses oil pressure. Negative feedback may be conceived generally as a type of regulatory restraint by which the values of a system's crucial variables are maintained within a range compatible with sustained operation. The central role of negative feedback in the economy of an operating system, to paraphrase Ashby ([9.7], 199), thus is to block the transmission of excessive variety to a system's protected variables. An important result of feedback regulation is to maintain the system at a state of low entropy relative to its operating environment.

Entropy

As originally defined by Clausius, entropy measured the proportion of total energy within an isolated system that is available for doing useful work. If part of a system is significantly hotter than another part (e.g., a steam chamber), then work can be done as heat passes from the hotter to the colder part (e.g., the pistons of a steam engine). If all parts of the system are at approximately the same temperature, however, the heat energy within the system is incapable of accomplishing useful work. According to the first law of thermodynamics, the total energy within a closed system remains unchanged through time. But as its energy available for work becomes expended through irreversible physical

processes (e.g., discharge of steam into the pistons), its capacity to produce additional work progressively decreases. This means that the entropy of the system, in Clausius's sense, progressively increases. The second law of thermodynamics, originally stating that the energy available for useful work within a closed system tends to decrease with time, thus received concise restatement to the effect that the entropy within a closed system tends always to increase.

The concept of entropy was provided with a statistical basis through the work of Boltzmann and Planck, beginning with Planck's definition of 'complexion' as a specific configuration of its components on the microlevel of a physical system. Boltzmann developed techniques for quantifying the proportion of a system's possible complexions correlated with each of its distinguishable macrostates. Under the assumption that all complexions of a system are equiprobable, he then established the a priori probability of its existing in a given macrostate as equal to the proportion of complexions associated with that macrostate to the total number of possible complexions of the system overall. In this treatment, the greater the proportion of complexions associated with a given macrostate (i.e. the greater its probability), the less highly organized the system will be when existing in that macrostate, and the less capable accordingly of producing useful work. This enabled a redefinition of entropy in terms of probabilities. If P is the probability of a system's existing in a given macrostate, and k is the quantity known as Boltzmann's constant, then the entropy S of the system in that macrostate is given by the equation '$S=k \log P$'. (Logarithms were used in this function to make entropy additive.)

As a result of Boltzmann's treatment, an increase in entropy came to be understood not only as a decrease in energy available for useful work, but also as a decrease in organization (structure, order) of the system concerned. Yet another formulation of the second law of thermodynamics now became appropriate: closed systems tend to become configured into increasingly more probable macrostates, which is to say macrostates exhibiting increasingly less order. What this means in practical terms is familiar to anyone responsible for cleaning house, or for keeping weeds out of a vegetable garden.

Further development of the concept of entropy came with its extension into the mathematical theory of communication. The relevance of this extension appears with the reflection that our information about the specific microstructure of a given system derives largely from observation of its macrostates, and that the more complexions there are that might possibly underlie a given macrostate the less information we have about its actual microstructure in particular. The situation is analogous to that of a detective with a general description only of a wanted person: the more people there are who fit

the description, the less information at hand about the actual culprit. When entropy is taken as a measure of the variety of microstates that might underlie an observable macrostate of a system, as in Boltzmann's application, then it also provides a measure of our lack of information about the structure of the system on the microlevel.

Information

Communication theory, pioneered by Nyquist and Hartley in the 1920s and formulated systematically by Shannon in 1948, is the study of the efficient transmission of messages through a communication channel. In its most general form, a communication channel consists of an input ensemble (A) of symbols (a_1, a_2…a_r) and an output ensemble (B) of symbols (b_1; b_2,…b_s), statistically interrelated by a set of conditional probabilities ($P(b_j/a_i)$ specifying for each output bj the probability of its occurring in association with each input a_i. For purposes of formal descriptions, both A and B are assumed to include a variety of symbol events, one and only one of which occurs at a significant moment of system operation. A simple illustration is a telegraph circuit, where A and B are comprised by events at the key and sounder, respectively, with conditional probabilities $P(b_j/a_i)$ determined by the physical characteristics of transmitting medium.

Because of the variety of symbol events at the input, there is uncertainty in advance (a priori probability less than 1) about what event (E) will actually occur there at a given moment of operation. This uncertainty is removed when E actually occurs (with an a posteriori probability of 1). The removal of this uncertainty is designated 'information'. Information varies in quantity with the amount of uncertainty removed by E's occurrence, according to the formula 'I(E)=log 1/P(E)'. (As in the equation defining thermodynamic entropy S, logarithms are employed here to achieve additivity. Logarithms to the base 2 are commonly used for convenience in application to digital computers.) If E has an a priori probability, say, of 50 per cent (think of a flip of an unbiased coin), then the information provided by its occurrence measures log 1/0.5 (=log 2), which amount to 1 bit (for '*bi*nary unit') of information. In general, the amounts of information provided by the occurrence of a given event is identical to the number of times (e.g., 1.74 for an event 30 per cent probable) its a priori probability must be doubled to equal unity.

The average information (H(A)) available at A is the sum of the quantities of information provided by its individual events, each multiplied by the event's probability of occurrence. It is easily shown mathematically that H(A) increases both with number of independent

events at A and with the approach of these events to randomness, i.e., to equiprobability. Because of this (and because of the similarity of the mathematical définition of H(A) to that of thermodynamic entropy S), the quantity H(A) is often called the 'entropy' of A.A related measure is the 'equivocation' (H(A/B)) of A with respect to B, which is the average amount of uncertainty remaining about events occurring at input A after the occurrence of associated events at output B. This quantity is given by the sum of the conditional probabilities of each event a; given each event b_j in turn, each probability being multiplied by the logarithm of its reciprocal. This quantity approaches zero as events at B increase in reliability as indicators of events at A, which makes H(A/B) a negative indicator of a channel's reliability as a conveyor of information. The capacity of a channel overall for the conveyance of information is directly proportional to the information available at its input and indirectly proportional to its equivocation. A channel's capacity in this regard is referred to as its 'mutual information' (I(A;B)), and accordingly is measured by the quantity H(A)-H(A/B).

While communication theorists typically are concerned with the design of channels for technological applications, communication channels play prominent roles in many natural processes as well. Communication of information in a natural setting often involves complex sets of channels known as 'cascades'. A cascade of channels consists of a sequence of individual channels so arranged that the output of the first serves as the input of the second, and so on *seriatim*. A perspicuous illustration is the cascade beginning at the cornea, and proceeding serially through the lens, the several layers of the retina, the optic chiasma, and eventually to the optical cortex. Each individual channel along the way has an integral part to play in the information-processing that constitutes visual perception.

A fact stressed by Shannon and other pioneers of communication theory, but too often unheeded by cognitive theorists employing an 'information-processing' vocabulary, is that information in this technical sense (information(t)) has very little to do with meaning or cognitive content. The symbol events with which communication theory deals might receive meaning under interpretation by human users, but by themselves have no semantical characteristics whatever. One of the major challenges of cybernetics is to gain insight into how information(t) can be converted by processes in the nervous system into information with cognitive significance (information(s))—into information in the sense of knowledge or intelligence. It is no service to clarity to assume, as is common in cognitive theory today, that information(s) appears 'ready-made' at the inputs of the central nervous system.

Negentropy

As entropy is a measure of a relative lack of information(t), so information(t) corresponds to a lack of entropy. The expression 'negative entropy' was used by Wiener ([9.5], 64) in describing information(t) as the absence of entropy, and was later shortened by Brilluoin to 'negentropy'. Other forms of negentropy are structure (departure from random arrangement of a system's components) and productive energy (capacity within a system for useful work). These three forms of negentropy are mutually convertible.

Energy is converted into structure when water is pumped into an elevated reservoir. And structure is converted to energy in turn when water falls to drive the turbines of a generator. Energy is converted into information(t) with the detection of a signal on a modulated radio wave. Structure is convertible to the same effect in the operation of a computer by a coded punch card. Inasmuch as information(t) is basically a statistical quantity, its conversion into structure and energy is harder to illustrate; but an intuitive sense is provided by the thought-experiment known as 'Maxwell's demon'. The 'demon' in question is situated along a passageway connecting two containers of gas, and operates a trapdoor controlling access of individual molecules to either chamber. Initially this (closed) system is in a state of maximum disorder (maximum entropy), with gas molecules distributed randomly from moment to moment. The 'demon', however, is capable of receiving information(t), distinguishing slow-from fast-moving molecules, and of admitting only fast into one chamber and only slow into the other. As an eventual result of the trapdoor's operation, the system reaches a state of maximum structure (segregation of molecules by rate of motion) and of maximum usable energy (temperature difference between chambers due to molecular impact), both purchased by the information(t) that enables the 'demon' to discriminate rates of motion. Entropy re-enters the picture with the observation that actual transformations of this sort among forms of negentropy generally involve some loss of usable energy, in accord with the second law of thermodynamics.

An important principle of communication theory (Shannon's tenth theorem) states that a system can correct all but an arbitrarily small fraction of errors at its input if its equivocation H(A/B) is no greater than the mutual information I(A;B) of its correction channel. An equivalent formulation is Ashby's law of requisite variety, to the effect that a device's capacity to serve as a regulator (to block variations producing instability) cannot exceed its capacity as a communication channel (marshalling variation for the communication of information (t)).

EXPLANATORY PRINCIPLES AND METHODOLOGY

Cybernetics has been conceived from the start as a unifying discipline, providing continuity across the borderlines of more specialized sciences ([9.5], 2). It has drawn freely upon the explanatory resources of other disciplines, but always with an eye towards applications beyond the boundaries of their original employment. As the biological concept of homeostasis was extended by Ashby ([9.17]) to the design of machines with adaptive capacities *(Design for a Brain),* for instance, so the physical concept of entropy was extended into biology with the work of Schrödinger ([9.14]). Observing that all natural processes produce increases of entropy in their general vicinity, Schrödinger characterized life as the capacity of an organism to resist progressive entropy in the form of structural loss by 'continually sucking orderliness from its environment' (Ibid., 79). The 'essential thing in metabolism' he remarked, 'is that the organism succeeds in freeing itself from…the entropy it cannot help producing while alive', which it accomplishes by 'feeding' on negentropy at the expense of an accelerated progression of entropy in its immediate locale. This characterization highlights the remarkable ability of living organisms to receive energy from foodstuffs existing at lower energy levels than themselves, comparable in effect to a toaster being warmed by a cold piece of bread. It is by reversing otherwise natural flows of energy in this manner that a living system maintains itself, as Wiener puts it, 'as a local enclave in the general stream of increasing entropy' ([9.6], 95).

Another biological concept with broad application in cybernetics is that of adaptation. Homeostasis itself is an adaptive process, as are other forms of negative feedback. Among organisms functioning in variable environments, moreover, there is a tendency to adjust their feedback capacities in response to pervasive environmental change, which amounts to an adaptation of adaptive capacities. Species evolution itself provides examples of this higher-level adaptation, as in the development of spiny leaf structures by plants adjusting their moisture-conserving procedures to increasing levels of infrared radiation. While the interest of evolutionary biologists in such adjustments is likely to focus upon the underlying genetic mechanisms, however, interest from the cybernetic point of view will lie more with their effect upon the interchange of negentropy between organism and environment. The primary role of such adaptive processes, from this point of view, is to maintain an efficient coupling between organisms and environment by which the organism can gain the negentropy needed to sustain its vital processes. By way of augmenting Schrödinger's characterization, it may be said that a living

organism not only is capable of receiving negentropy from its proximate environment, but also belongs to a reproductive group that tends to preserve this capacity throughout its membership by adaptive changes in the feedback mechanisms involved.

While relying upon other disciplines for certain of its explanatory principles, cybernetics also has developed explanatory resources of its own which would not fit comfortably into the specialized sciences. One is the principle of mutual convertability among energy, structure and information, cited above as being due largely to Brillouin. Another is the aforementioned law of requisite variety, in which Ashby reformulated Shannon's tenth theorem of communication theory in terms directly germane to the feedback capacities of living organisms. According to this law, the range of environmental variation to which an organism can adapt is limited by the capacities of its information(t)-processing systems. A consequence is that a large amount of the negentropy received by highly adaptive organisms like the human being must come in the form of information(t), and that a large portion of their physiological structure must be devoted to processing this information(t). This result is basic to a cybernetic analysis of human mental capacities.

These considerations make clear that the sense in which cybernetics is a unifying discipline has little in common with the 'unity of science' projected by logical positivism in the early twentieth century. While this latter was to have been achieved by way of reduction to physics, cybernetic theorists from the beginning have been explicit in denying primacy to the physical sciences ([9.6], 21; [9.7], 1). The biological principles upon which cybernetics relies are no more reducible to physics than its physical principles are reducible to biology; and neither science can deal with information(t) as a form of negentropy. The manner of unification offered by cybernetics is rather that of a context in which comparable phenomena from diverse disciplines can be studied in common terms, without loss of autonomy of the part of the disciplines concerned.

Because of its essentially interdisciplinary character, there is no single method or set of methods by which cybernetics can be distinguished from related fields of enquiry. The experimental techniques of neurophysiology and control engineering were important to cybernetics at its inception, along with the more formal methods of mathematical logic, calculus and the theory of computation. In recent years, cybernetic studies have employed techniques of systems analysis, organizational theory and computer modelling as well. From this it follows not that anyone employing these techniques of investigation *ipso facto* is engaged in cybernetics, nor that being engaged in cybernetics requires employing one or more of these techniques, but only that someone might employ any of these methods in cybernetic inquiry.

What is methodologically distinctive about cybernetics is rather the way in which it undertakes to bring the diverse resources of allied fields of study into mutual relevance. As an integrative discipline, cybernetics is more philosophy than science. In his quasi-autobiographical account of how the discipline came into being, Wiener cites Leibniz time and again (at one point naming him 'patron saint' of the field ([9.5], 12), and mentions the influence of Royce and Russell as former teachers. Among other philosophers favourably noted are Pascal, Locke, Hume and Bergson. While acknowledging debt to these thinkers in various respects, Wiener seems particularly sympathetic with their interest in metascientific issues, and with their sense of how philosophy informs the foundations of science. The way in which cybernetics was pursued by Wiener is not unlike the way philosophy has been pursued by its major exponents throughout the centuries. Its manner of proceeding, in most general terms, was to adopt a few basic concepts and principles of elucidation, and in terms of these to elaborate a coherent picture of the world at large. For Wiener, the basic concept was that of system or organization, and the principles of elucidation those of feedback and communication. Due perhaps to the predominantly scientific orientation of other members of his original group, however, there seems to have been little incentive to work out the ramifications of this methodological perspective in detail.

A specific mode of enquiry that has proven serviceable to cybernetics in its more recent development is patterned after a familiar method of philosophic analysis. In its typical philosophic application, the method begins with a necessary feature of the concept or kind being analysed, and proceeds by adding other features until a combination is found that characterizes all and only instances of the thing in question. Successfully completed, the procedure yields a characterization unique to the thing being analysed, in terms of its necessary and sufficient conditions. In its specifically cybernetic application, the procedure is concerned instead with complex systems and their modes of behaviour, and the techniques of analysis might be experimental (e.g., in mechanical or computer simulations) as well as conceptual; but in other respects the procedure is similar. Beginning with a component of the complex structure under investigation, it proceeds by combining other components in some appropriate order until the structure in question has been exhibited (mechanically or conceptually) as a combination of parts. What marks the procedure as specifically cybernetic is the character of the components with which it deals, and (in application to biological systems especially) the order in which these components are appropriately combined. The components will have to do typically with the regulation of the system, and with its management of information(t) and other forms of negentropy. In biological applications, moreover, and in any other where

the structures being studied show signs of having evolved from less complex substructures, the order of combination should follow lines of plausible evolutionary development.

This procedure overall might be characterized as a form of analysis by synthesis, or what in recent philosophy of mind has been called 'bottom-up' (in contrast with 'top-down') analysis. The synthetic or integrative bearing of the method is philosophical in character, and is directed towards understanding a complex structure in terms of its functional components. The components themselves are understood, as indicated above, according to the explanatory resources of the specialized sciences. The methodology of cybernetics thus is both philosophic and scientific, and might be pursued in a study as well as in a laboratory.

ANALYSIS OF GOAL-DIRECTED BEHAVIOUR

Among the earliest indications of the interdisciplinary and more broadly philosophic implications of the concept of negative feedback was the paper 'Behavior, Purpose, and Teleology' published by Rosenblueth, Wiener and Bigelow in 1943 ([9.12). The seminal idea of this paper, in Wiener's estimation ([9.5], 8), is that the central nervous system does not function as a self-contained organ, taking inputs from the senses and issuing outputs into the musculature, but that it characteristically acts instead as part of a negative feedback loop circling from the effector muscles out through the environment and back again through the sensory system. The neurological research that led to this insight had been concerned with goal-directed behaviour like picking up a pencil, and the authors saw fit accordingly to illustrate the type of feedback involved by the target-seeking missiles being developed as part of the current war effort. Weapons of this sort are guided by some sort of communication link (sounding-echoing, magnetic, thermal, etc.) with the intended object, through which an error-correcting mechanism operates to maintain the missile on a course leading to contact with the target. In their initial enthusiasm for this analogy between human and overtly mechanical feedback operations, the authors proposed target-seeking behaviour of this sort as a model for goal-directed (purposive, teleological) behaviour generally.

A telling difficulty of this model raised in subsequent criticism is that target seeking of this sort requires the physical presence of the intended goal, whereas human purposive behaviour (e.g., searching for a lost earring) is often directed towards goals that are absent. What has been taken as teleological activity in biological processes (e.g., growth of an oak from an acorn), similarly, appears to be directed toward goal states

(e.g., the morphology of a mature tree) that are present, if ever, only late in the process. A model of goal-directed behaviour better suited to this wide range of examples is based upon the concept of equilibrium or stability, and stresses the manner of direction rather than the (external) goal itself. The missile is guided to its target by feedback mechanisms designed to maintain a stable correspondence between its actual motion and the path leading to impact with the target; from the guidance system's standpoint (although not the designer's) the resulting impact is coincidental. When loss of an earring disrupts a person's morning toilet, the search-behaviour ensuing is guided by feedback procedures (search patterns) directed towards restoring equilibrium to the person's dressing routines. And when an acorn begins to sprout and sends down its roots, its subsequent growth is guided by genetically established feedback processes towards a state of stable homeostasis (that of a fully leaved tree) within its living environment. Goal-directed behaviour in each case is governed by negative feedback, and is aimed at establishing or maintaining some facet of the operating system in a state of equilibrium.

Sharing this general form of goal-directed behaviour does not relegate either human purpose or biological teleology to the mechanical status of target-seeking missiles. Artifacts like guided missiles typically are engineered to perform certain predetermined operations when functioning properly under certain conditions, such that failure to perform accordingly under those conditions would be an indication of system malfunction. Human acts performed on purpose, however, are to some extent discretionary, which means *inter alia* that failure to perform when conditions warrant does not indicate a breakdown of the feedback systems involved. Human purpose in this sense is not deterministic, and thus is in accord with the general restriction in the cybernetic framework against deterministic explanations of natural processes at large (see below). Teleological growth is distinguished from target-guided behaviour, in turn, not only by being directed toward an absent goal, but also in that the goal-directed activity involved takes the form of morphological change rather than change in vectored motion. At any stage of its morphological development, an organism must relate to its immediate environment with sufficient stability to acquire the negentropy it needs to remain alive. Only at a relatively advanced stage of growth, however, does an organism achieve homeostasis in a form that can be maintained without further morphological change (exfoliation of leafy structure, growth of teeth, etc.). The sense in which biological growth is ideological is that it is directed toward a goal state which arrives literally only towards the end of the growth process itself, which is a state of stable homeostasis within the living environment. In view of the fact that such growth is guided by feedback mechanisms set

in place by the organism's genetic structure, however, there is no call to interpret biological teleology as a causal process in which cause follows effect. The biological basis of teleology and its causal structure are examined more fully in [9.9].

FORMS OF ADAPTATION

Morphological development is guided primarily by the genetic mechanisms of the individual organism. Another form of change to which organisms submit is adaptation, which occurs primarily in response to environmental variations. Among modes of adaptation that had been studied systematically before the advent of cybernetics are evolution and natural selection among biological species, and the behavioural conditioning of individual organisms. Cybernetic analysis of the feedback characteristics shared by these modes of adaptation led to the discovery of another mode pertaining to the formation of perceptual patterns, which appears significant for our understanding of cognitive processes.

Evolution and Natural Selection

A biological species is a group of interbreeding individuals with traits transmitted genetically to succeeding generations. Membership of a local subgroup (deme) of a given species fluctuates with changes in local conditions, as more or fewer members live to maturity in response to variations in food supply, predation, etc. Adjustments to short-term environmental variations of this sort generally occur without significant alteration of the group's genetic pool, and hence without alteration of the traits typically shared by its membership. Adjustment to more pervasive environmental changes like geophysical upheaval or shift in climate, on the other hand, may require alteration of a group's specific traits, enabling its members to take advantage of new food sources (e.g., thicker beaks for cracking seed shells) or new means of protection (e.g., lighter colouration for a snow-covered habitat). Long-term adaptation of this sort may be initiated by a shift in reproductive dominance to individuals within the group already approximating the features in question, which thereby become proliferated among members of subsequent generations. An eventual result may be the emergence of a reproductive group based on a genetic pool sufficiently altered to constitute a new species. Species evolution thus may be viewed as the product of a homeostatic process that enables reproductive groups to maintain stability under changing environmental circumstances. The mechanism of adjustment is alteration

of the genetically controlled traits affecting the group's viability within its immediate environment.

Whereas species evolution is an adaptive process operating on the level of the reproductive group, natural selection in turn is an adaptive process on the level of the biota or ecosystem. A biota is a system of species interacting within a shared environment, each occupying a distinctive role or niche in which it can maintain stable relationships with its companion species. Niches are distinguished by the kinds of living space (trees, meadows, etc.) and food source (seeds, insects, etc.) they provide. The normal state of a biota is to provide all the niches needed to keep its community in balance, and at the same time to keep its existing niches full with as many individuals as the negentropic resources of its locale can sustain. Momentary decreases in population within a given niche may be countered by increased reproduction on the part of its occupying species, or by the immigration of competing species from adjacent locales. Excessive increases in population, on the other hand, will be countered by decreased reproduction, perhaps in the form of the extinction (or severe depletion) or one or another competing group. When competition for the limited resources of a niche puts a newly emerged species at hazard, the eventual result will be either its irradication by a more competitive species or its establishment as part of a well-balanced ecosystem. Natural selection thus may be viewed as a homeostatic process by which an ecosystem maintains integrity in a changing environment by changes in relationship among its constituent species.

Learning

Failure of a newly emerged species in its original biota does not preclude success in some other locale to which it may have migrated. Characteristics that enable a group to perform competitively in various locales (part of what above was termed 'negentropic flexibility') thus provide multiple opportunities for success, and are likely to become part of the group's genetic endowment. A major provision of this sort appeared in the course of species evolution with the ability of individual organisms to adapt their behaviour to local changes in their immediate environment. Whereas adaptation of primitive life-forms like bacteria and protozoa depends upon genetic mutations affecting the species at large, and hence requires a period of several generations, adaptation of individual behaviour to immediate contingencies can occur repeatedly within the lifetime of a single organism. This ability is known in behavioural science as 'conditioning' or 'learning'.

Any operating system produces outputs that are conditional to some

extent upon its inputs. A system is capable of learning when it can adjust this conditional association between input and output to its own benefit. While a biological system in an entirely fixed environment would gain nothing by such an adjustment, a complex organism in a variable environment will generally benefit from some behaviour patterns and be harmed by others. Organisms capable of learning have been genetically disposed to avoid adversive (painful or 'punishing') stimuli and to seek stimuli they find agreeable (pleasant or 'reinforcing'). Inasmuch as natural selection will favour species whose members are reinforced under beneficial circumstances, and are punished by harmful, the effect of this disposition in an enduring species is to support survival of the individuals in which it operates. Learning then boils down to a process of shaping the behaviour of organisms to elicit predominantly agreeable stimuli from their current environments, and to minimize the occurrence of adversive stimuli, with the long-term result of enhancing the survival probabilities of the species involved.

In favourably conditioned organisms, stimuli indicative of beneficial circumstances will tend to elicit behaviour likely to secure those benefits, while stimuli indicative of harmful circumstances will tend to elicit avoidance behaviour. But when an organism begins to find adversive stimuli associated with previously beneficial circumstances (e.g., a once clear stream showing signs of contamination), or vice versa, the organism will undergo significant changes in the probabilities of its behavioural outputs conditional upon inputs signalling the presence of those circumstances. Inputs previously prompting the organism to take advantage of the circumstances they signify will now tend to elicit avoidance behaviour instead, or perhaps will simply lose their power to elicit any distinctive behaviour whatever. And vice versa for inputs previously leading to avoidance behaviour. By thus adjusting its conditional probabilities between sensory inputs and behavioural output in response to changing 'contingencies of reinforcement' (the phrase comes from Skinner ([9.23])), the organism adapts its behaviour to a changing environment. In its most general cybernetic description, learning is a feedback process in which the environmental effects of an organism's behaviour are channelled back through its sense receptors, and used to shape that behaviour in patterns conducive to the organism's advantage under current environmental circumstances.

Perceptual Patterning

According to Ashby's law of requisite variety, the range of environmental variation to which an organism can adapt its behaviour is limited by its capacities as an information(t)-processing system. A straightforward

consequence is that the variety of adaptive responses an organism can make to a fluctuating environment is limited by the variety of circumstances distinguishable within its afferent nervous system. Cybernetically inspired experiments at MIT in the 1950s indicated that frogs, for example, are capable of distinguishing only five or six different patterns of stimulation in their visual environment, one being a spot the size of a fly moving a frog's tongue-length away in front of its eyes. The frog's behaviour in its biotic niche is confined to responses to these distinctive patterns (and a few others like them pertaining to other sense modalities), each of which is communicated through a set of nerve fibres dedicated to that pattern specifically. With this method of information(t)-processing requiring a one-to-one correspondence between message channel and message type, a radical extension in the number of patterns distinguishable by the animal's afferent system would require additional bulk that could impair its mobility. Perceptual patterning of this sort might be described as 'hard-wired', rather than adaptive in the manner of more advanced visual systems.

A major advance in adaptive capacity came with the evolution of organisms able to extend radically their range of discriminable circumstances without corresponding increase in bulk of their afferent nervous systems. The manner of information(t)-processing making this possible permits different stimulus patterns shaped in response to different environmental circumstances to pass through a single integrated network of afferent channels. This expedient of adaptive pattern-formation is similar in its feedback characteristics both to evolution and natural selection (adaptation on the species level) and to behavioural conditioning (adaptation on the level of the individual organism), and might be conceived alternatively as a very rapid evolution of afferent neuronal structures or as a much accelerated learning of the sensory system.

By 'perceptual pattern' here is meant a more or less specific set of neuronal events that occur interactively in response to a more or less specific configuration of external events in the perceptual environment. Between the external configuration and the neuronal pattern will extend a cascade of information (t)-channels (e.g., external object to cornea to lens to retina to optic chiasma, etc.), each serving both to convey relevant information(t) into the upper reaches of the afferent system and to help forge the features of the resulting pattern along the way. The key function of the cascade overall is to fashion a configuration of neuronal events that stands in a relation of high mutual information (see above) with the configuration in the external environment. If the mutual information between external and neuronal configuration is sufficiently high (i.e., they are sufficiently alike in information(t)-structure), then the latter will serve the organism as an effective guide of behaviour it undertakes with respect

to the former. The latter in this respect is an adequate 'representation' of the former.

A corollary of Ashby's law cited above is that organisms under selective pressure to increase their variety of adaptive behaviours will be under pressure as well to employ their information(t)-processing channels as efficiently as possible. Efficiency might be served by various 'noise reductions', 'boundary tracing' and other information(t)-processing techniques of sorts well studied by communications engineers, performed at various stages along the cascade (e.g., at the retina or optic chiasma). The result is a neuronal representation of largely 'schematic' character, incorporating less detail than might be had at earlier stages in the cascade. If more detail proves necessary for successful guidance of behaviour undertaken with regard to what is represented, or if different representations are required to guide other behavioural projects, adjustments are made throughout the cascade to produce patterns at the upper afferent levels with informational(t)-features adequate to the task at hand.

Pattern-formation procedures of this general sort join with the efferent faculties of the behaving organism to constitute a homeostatic system, the normal state of which is a series of afferent patterns providing perceptual guidance for the organism's ongoing behaviour. Deviation from the norm is indicated by incipient loss of perceptual control, and the system regains stability by restructuring the representations by which this behaviour is currently being guided. Recent theoretical analysis suggests that perceptual pattern-formation of this sort provides a basis for certain cognitive processes typical of the human organism specifically.

HIGHER COGNITIVE FUNCTIONS

Similarities in feedback characteristics among the processes of natural selection, learning and perceptual patterning, have been extensively explored in cybernetic literature. Parallels in natural selection and learning were pointed out by Wiener [9.5], 181), and were further developed by Skinner ([9.23]). An empirical basis for the account of perceptual patterning outlined above was proposed by Sayre ([9.9]). Extensions of this line of analysis to higher cognitive functions like language use and reason remain more conjectural. The brief discussion following is an indication of potential rather than actual accomplishment.

In a perceptual environment providing regularly recurring stimulus configurations, the afferent system of a perceptually adaptive organism may develop standard representations which find employment time and again in the pursuit of its perceptually guided

projects. Such representations, which might be labelled 'percepts', are normally activated by stimulation of the external sense organs, and in this sense are controlled by the external environment. Percepts available to a given organism would typically include representations of familiar plants, animals, etc. Individuals of species capable of language will also form percepts responding to symbol configurations issued by other members of their linguistic community. To learn the language of one's community is to learn to associate percepts representative of familiar objects with other percepts representing the standard symbols of the language (at first vocal, later written, etc.), in such a fashion that the former percepts are capable of being activated by the latter. Percepts that in this fashion have been brought under the control of linguistic symbols, as well as of the objects they standardly represent, may be referred to as 'meanings'.

Meanings in this sense are not abstract entities, but rather well-entrenched neuronal patterns capable of functioning in the actual information(t)-processing activities of linguistically competent organisms. Since the essential feature of a given meaning structure is its relation of mutual information with the object it represents, and since physically different structures can share in this relation with a single given object, the same meanings can be present in different organisms. Linguistic communities emerge as many individuals learn to activate the same meanings upon presentation of the same symbol configurations, and to associate those symbols with the same objects in their shared environment.

Meaning B may be said to be redundant relative to meaning A when all features of the world represented by B are represented by A as well. The meaning 'ripe' applied to grapefruit, for instance, renders the meaning 'yellow' redundant. Conversely, applicability of 'yellow' to a given grapefruit is required for 'ripe' to be correctly applicable. The former controls the latter in this connection by restricting the circumstances of its correct application. Concepts may be conceived as meanings that have been removed from exclusive control of perceptual configurations (either linguistic symbols or objective circumstances), and brought under the control in this fashion of other meanings. While the percept 'yellow' is activated only by yellow objects, and the meaning 'yellow' either by objects or their linguistic symbols, the concept 'yellow' can be activated not only by objects and symbols, but in certain applications also by the meaning 'ripe'. Understood in this fashion, percepts, meanings and concepts are all stable structures of neuronal activity, distinguished with regard to their manner of control.

Concepts may be said to participate in a shared linkage if they are mutually relevant to each other's application, perhaps conditional upon the applicability of other concepts within the same linkage. The concepts

'ripe', 'yellow' and 'soft' thus share linkage with the concept 'grapefruit', reflecting the coincidence of colour and tactual properties discovered through the experience of a linguistic group with palatable grapefruit. If a variety of grapefruit were encountered in which a colour other than yellow (say, pink) turned out to be a more reliable sign of palatability, however, the relevant conceptual linkages of the individuals undertaking to eat this fruit would soon adapt to this novel set of circumstances. Due to the public nature of the language from which these concepts are derived, it would not be necessary for other individuals to undergo the same experiences themselves for their conceptual linkages to be appropriately modified. They can be modified through conversation with the individuals first affected. Conceptual linkages thus serve as facilities of information storage, subject to homeostatic adjustment and augmentation through the experiences of subgroups within the linguistic community. Such linkages in effect are neuronal mappings of regularly associated objective circumstances, subject to adaptation by continued encounters with a shared living environment. By using these maps to chart the course of anticipated behaviour, rational agents can explore alternatives before committing themselves to action.

RELATION TO ALTERNATIVE PARADIGMS

Cybernetics has been guided from the outset by the conviction that a wide range of human mental functions can be reproduced mechanically. Among Wiener's original associates in the 1940s were several figures (e.g., O.G.Selfridge, W.H.Pitts, W.S.McCulloch) who subsequently became known for contributions to AI. Spokesmen for cybernetics up through the late 1970s, (e.g., F.H.George, K.Gunderson, K.M.Sayre) still considered AI to be an integral part of that discipline. The original ties between cybernetics and AI were effectively severed during the 1980s, however, to the extent that early contributors to machine intelligence who had remained closely identified with the former movement (e.g. W.R.Ashby, D.M.MacKay, F.H.George, Wiener himself) are seldom cited in current histories of the latter. This divorce appears to have been due largely to the recent takeover of AI by the computational paradigm, and to an ideological slide towards materialism on the part of its advocates.

Materialism, in its bare essentials, is the doctrine that everything in the universe comes under the purview of physical science. The primacy of physics in this regard was challenged in Wiener's original manifesto ([9.5], ch. 1; see also [9.6], 21), and was explicitly rejected in Ashby ([9.7]). Wiener's disavowal was based in part upon his realization that the determinism implicit in classical physics is

incompatible with the variety inherent in biological processes. A theoretical basis for rejecting determinism in the natural world generally lies in the principle (a version of the second law of thermodynamics) that all irreversible processes tend to involve a loss of negentropy, which entails that causes generally tend to be more highly structured (involve less variety) than their effects. A consequence, as Wiener puts it, is that even the most 'complete collection of data for the present and the past is not sufficient to predict the future more than statistically' ([9.5], 37). Ashby's repudiation of materialism was more direct, pointing out ([9.7], 1) that the materiality of the systems studied by cybernetics is simply irrelevant. Some organized systems (e.g., computers) are strictly physical, while others (e.g., linguistic communities) quite probably are not; and the fact that systems of both sorts can perform comparable feedback and information(t)-processing functions is no indication that they share the same ontological status. It should be noted at the same time, however, that the likely non-physical status of some cybernetic systems does not convert automatically into evidence for dualism. Contrary to current dogma in some quarters that materialism and dualism are the only ontological options on the horizon, a more plausible alternative from the cybernetic point of view is some version of neutral monism (as in Spinoza or early Russell). Sayre attempts to articulate a monism in which neither information(t)-functions of cognitive activity nor probabilistic functions at the quantum level of matter are further reducible to mental or physical features, making mathematical (statistical) structures more basic ontologically than either mind or matter [9.9].

The computational paradigm in recent AI and cognitive science rests upon the thesis that cognitive processes are computations performed upon representations, where the computations in question are of the sort typified by a standard digital computer. Barring the arbitrary introduction of randomizing elements, the computations performed by a properly operating digital computer are deterministic in outcome, which means that the same input invariably produces the same output. Even when the machine is computing probabilities, its procedures of computation are deterministic in this fashion. This makes mechanical computation an inappropriate model for indeterministic natural processes in general, and especially so for the highly negentropy-intensive (entropy producing) cognitive functions of human organisms. This difficulty, coupled with the well-known conceptual problems computationalists have encountered trying to account for the semantic properties of mental representations (discussed in [9.22]; [9.21] and elsewhere), should dispose anyone

approaching cognition within a cybernetic framework towards disfavour of the computational model.

A more sympathetic reception may be accorded the connectionist paradigm that emerged during the late 1980s, which portrays various forms of cognitive activity as informational exchanges within a network of interconnected nodes with varying weights and excitation levels. Description of these networks is often couched in terms of conditional probabilities, and hence could be recast without distortion in the technical terminology of communication theory. Connectionist researchers have already begun to study certain feedback characteristics of such systems, along with certain ways in which they might function in the control of motor behaviour ([9.19], 84). If attention were directed as well towards how these networks might adjust homeostatically in response to changes in a cognitively stimulating environment, connectionism might produce significant insight into the cybernetic workings of our cognitive faculties.

CHAPTER 10

Descartes' legacy: the mechanist/vitalist debates

Stuart G.Shanker

I DESCARTES' DOMINION

> Why, man, he doth bestride the narrow world
> Like a Colossus, and we petty men
> Walk under his huge legs and peep about
> To find ourselves dishonourable graves.
> Men at some time are masters of their fates.
> The fault, dear Brutus, is not in our stars,
> But in ourselves, that we are underlings.
>
> (*Julius Caesar* Act 1, Scene 4)

Rare is the philosopher of psychology who has not felt like Cassius at some point in his career. For there is no other port of entry into the field than through the legs of Descartes. Even those—or perhaps, especially those—who have sought a completely different route have ended up delivering eulogies to Descartes' greatness. Mechanist or vitalist, dualist or materialist, introspectionist, behaviourist, computationalist or cognitivist: succeeding generations have found themselves responding to Cartesianism in one way or another.

It is becoming virtually impossible these days to open a monograph in the philosophy of psychology without beginning with a chapter on Descartes. 'Descartes' Myth', 'Descartes' Dichotomy', 'Descartes' Dream', 'Descartes' Legacy': one begins to yearn for the chapter announcing 'Descartes' Demise'! But the problem is that Descartes really is a Colossus, and the final word in the history of his ideas will belong to a Marc Antony and not to a Brutus.

Descartes epitomises—and was widely seen by his contemporaries as having inspired—the enormous social, scientific and even religious

changes taking place in the Enlightenment. When Newton explained to Hooke how it was by standing on the shoulders of giants that he had been able to see further, it was specifically 'further than Descartes'. No doubt when the 'Newton of the mind' longed for by so many contemporary psychologists appears on the scene, he will say much the same thing.

Descartes represents the appeal to reason and self-responsibility over authority. It is in this respect that the *Discourse on Method* is such a revolutionary text: the paradigm of a modern revolutionary text. Not just the content, but even the very style in which it is written marks a radical break from the past. Descartes tells of how:

> returning to the army from the coronation of the Emperor, the onset of winter detained me in quarters where, finding no conversation to divert me and fortunately having no cares or passions to trouble me, I stayed all day shut up alone in a stove-heated room, where I was completely free to converse with myself about my own thoughts.
>
> ([10.4], 116)

We have grown so accustomed to the voice in which this is written that it requires a conscious effort to recover the period eye necessary to appreciate the full significance of this 'fragment of autobiography': i.e. that it is a fragment of *autobiography* (see [10.1]). Moreover, the tone of what follows in the text cloaks the extent to which Descartes was deliberately challenging the established order. Far more is at stake here than Descartes' anxiety to avoid a similar fate to that which befell Galileo. Hence, we must be careful not to allow the stories about Descartes' reluctance to publish *The World* to blind us from seeing what an extraordinarily bold work the *Discourse on Method* is: not so much because it provides us with any serious grounds to question Descartes' attitude towards the soul, but because of the truly revolutionary implications of the argument presented at the end of Part Five.

Descartes is here repudiating the orthodox doctrine of the 'Great Chain of Being'. He is insisting that there is a hiatus between animals and man that cannot be filled by any 'missing links'. The body may be a machine (which was itself a heretical view), but man, by his abilities to reason, to speak a language, to direct his actions and to be conscious of his cognitions, is categorically *not* an animal. There is no hint in the *Discourse* that any of these attributes can be possessed in degrees. Rather, Descartes' universe, unlike that of the Ancients, is bifurcated. And at its centre stands neither the Earth, nor the Sun, but the mind of the individual, responding to the world around it.

When Aristotle tells us that 'Man is by nature a political animal', or Seneca that 'Man is a reasoning animal', the emphasis is on *animal:* one analyses man as an *animal species* (see the opening chapter of Aristotle's *Metaphysics*). But all this is changed in the *Discourse*. Here we begin, not with humanity, but with René Descartes: with the thoughts of a solitary individual who has come to distrust the teachings of the finest minds of his time; who has renounced the blind homage to Aristotelian thought which so dominated medieval and Renaissance thought; who decided to continue his studies by reading from the 'great book of the world' rather than from the classics, and whose 'real education' has taught him to accept as certain only those ideas which he himself can see clearly and distinctly: *in his own mind's eye*. Descartes' revolutionary epistemology thus goes hand-in-hand with the social revolution; for what need is there for 'privileged access' when one has the writings of The Philosopher to fall back on?

The shock waves which this argument set off—and which it was intended to set off—were every bit as great as the effect of the *Cogito:* if not more so. What was initially hailed by the Cambridge Platonists as an act of heroism was soon to be castigated as an act of hubris. For the Great Chain of Being was not a doctrine which Western thinkers were about to abandon without a struggle. Gassendi swiftly recounted the classical line (in the Fifth set of Objections), seemingly unaware that Descartes' heresy was intentional (see [10.3], II:188). Similarly, the objections compiled by Mersenne in the sixth set defend the Great Chain of Being from what he perceived as Descartes' self-defeating sceptical attack (Ibid., 279). And in the third book of *An Essay Concerning Human Understanding* we find Locke arguing that: 'In all the visible corporeal world we see no chasms or gaps. All quite down from us the descent is by easy steps, and a continued series that in each remove differ very little one from the other.' The crucial corollary of this argument is that:

> There are some brutes that seem to have as much reason and knowledge as some that are called men; and the animal and vegetable kingdoms are so nearly joined, that if you will take the lowest of one and the highest of the other, there will scarce be perceived any great difference between them.
>
> ([10.11], III, vi, Section 12)

Significantly, when La Mettrie ridiculed 'all the insignificant philosophers—poor jesters, and poor imitators of Locke', it was not for defending this continuum picture, but for doing so on the wrong terms. He felt that the real lesson to be learnt from Descartes' 'proof that animals are pure machines' is that 'these proud and vain beings, more distinguished by their pride than by the name of men however much they

may wish to exalt themselves, are at bottom only animals and machines which, though upright, go on all fours' ([10.10], 142–3).

In other words, the defence of the Great Chain of Being could proceed in either of two directions: show how the behaviour of animals is intelligent, or that of man, mechanical. Two versions of the *continuum picture* thus emerged: the vitalist and the mechanist. The former sought to blur the lines between the higher animals and man via a *continuum of sentience;* the latter sought to reduce man to the level of the beasts by eschewing the appeal to consciousness. What was perhaps the greatest irony in the emerging debate between these two polarities is that both sides were to claim Descartes as their spiritual guide.

For the next two hundred years, the life sciences were dominated by the battle over Descartes' picture of the body. To begin with, the debate centred on Descartes' claim that 'It is an error to believe that the soul gives movement and heat to the body' ([10.6], 329). With the successful mechanist resolution of the theory of heat in the middle of the nineteenth-century (see section 2 below), attention shifted onto Descartes' picture of reflexive behaviour (see section 3), and thence, to psychology (see sections 3–4 below). For Descartes' attack on the Great Chain of Being is grounded in the fundamental distinction which he draws between *actions* and *reactions*.

Despite the common assumption by Cartesians that Descartes intended his argument to be read as an inductive hypothesis, it is never quite clear whether Descartes' denial of the possibility of purposive animal behaviour was meant as an empirical or as a conceptual thesis. Certainly it was interpreted and disputed as a hypothesis. In essence, his argument is that all bodily movements are caused by 'agitations in the brain', which in turn are triggered by two different kinds of event: external objects impinging on the senses, or internal mental acts or states. It is the fate of animals/automatons that they only experience the former phenomena while man experiences the latter phenomena as well.

This argument may seem to be directly opposed to the sentiments expressed in the above quotation from *The Passions of the Soul,* but the point Descartes is making there is simply that reflex movements are not volitional (cf. his reply to Arnauld in [10.3], II:161). The distinction operating here is that between *voluntary* and *involuntary movements*. Those that are involuntary occur 'without any intervention of the will', while 'the movements which we call "voluntary"' are those which 'the soul determines' (Ibid, 315). These 'volitions, in their essence (pure acts of the soul, terminating in itself) are limitless and disembodied, but all existing volitions (acts of the soul terminating in the body) are limited by the structure of embodiment' ([10.13], 109)- Most important of all: to the eye of the observer, voluntary and involuntary movements *look* exactly the same. It is only because each individual is able to see and report on his

own volitions that we are able to make this fundamental distinction between *voluntary* and *involuntary* movements, and because animals lack a similar capacity that they are ruled automata.

The argument that these acts of will are transparent to reason amounts to a doctrine of *epistemological asymmetry:* while I can *know directly* what causes my own actions, I can only *infer* that someone else's bodily movements are brought about by similar mental events. Hence, for all intents and purposes, the behaviour of other human beings stands on the same epistemological footing as that of animals. But the fact that

> There are no men so dull-witted or stupid…that they are incapable of arranging various words together and forming an utterance from them in order to make their thoughts understood; whereas there is no other animal, however perfect and well-endowed it may be, that can do the like.'
>
> [(10.4], 140)

warrants our adopting a stance of semi-solipsism towards our fellow man, but not towards the beasts. For even madmen can report on their volitions (the bodily movements caused by their will), but no animal possesses such a capacity.

This argument invited the obvious response that animals do indeed communicate, but in a language which we cannot understand (a point which led Gassendi to reiterate the orthodox line that, 'although [animals] do not reason so perfectly or about as many subjects as man, they still reason, and the difference seems to be merely one of degree' ([10.3], II:189)). But Descartes had already anticipated this objection when he argued that animals lack the sort of creative behaviour necessary to be credited with such an ability ([10.4], 141; cf. [10.2]).

It is highly significant for the history of psychology that Descartes immediately tied this theme in to the claim that reflex movements cannot be adaptative; for from this issue was to ensue the prolonged debate over the purposiveness of reflex behaviour. But before we examine the consequent evolution of mechanism, it is important to see how, despite all the modifications which reflex theory was to undergo, there is a sense in which this entire controversy completely missed Descartes' point.

In the second *Meditation* Descartes remarks how:

> If I look out of the window and see men crossing the square, as I just happen to have done, I normally say that I see the men themselves, just as I say that I see the wax. Yet do I see any more than hats and coats which could conceal automatons? I judge that

> they are men. And so something which I thought I was seeing with my eyes is in fact grasped solely by the faculty of judgement which is in my mind.
>
> ([10.5], 21)

This last sentence is absolutely crucial to understanding Descartes' argument, which is that *our minds* assume, on the basis of the similarity between the observed behaviour and our own, that the men crossing the square are not automatons. Our minds cannot *see* the causes of their behaviour, any more than they can see the causes of an animal's movements. But given the observable disparity between human and animal behaviour, there is no justifiable ground (psychological compulsion?) for the mind to extend its mental-causal schemata to the latter case.

For some idea of the extent to which this argument continues to dominate modern thought, one need only look at attribution theory. Heider approached the analysis of social interaction in terms of an inferential theory of perception: social no less than object judgements involve the classification of sensory information. Actions are 'stimuli' which must be 'categorized': they are seen as the effects of external or internal causes (where the latter are comprised of the mental processes and states with which the agent is acquainted in the case of his own actions). Our minds construct and continually revise inchoate theories as to how attitudes cause intentions and intentions cause actions; whether we are aware—whether we *could* be aware—of this mental activity is another matter (see [10.8]).

On this cognitivist reading of the continuum, we begin with the paradigm of the scientific mind, and work our way backwards through a descending level of 'cognitive schemes' until we arrive at a brute level of non-verbal processing. On the converse behaviourist picture of the continuum, there is no logical need to postulate such 'mental constructs' to explain the behaviour of other agents or lower organisms. At the beginning of this century, H.S.Jennings wrote about the continuity of 'the psychological processes' that constitute 'the bridge which connects the chemical processes of inorganic nature with the mental life of the highest animals' ([10.12], 508; cf. [10.9], ch. XX). This provoked a sharp rebuke from the young John Watson:

> Have we any other criterion than that of behavior for assuming that our neighbor is conscious? And do we not determine this by the complexity of his reactions (including language under behavior)?… If my monkey's adjustments were as complex as those of my human subjects in the laboratory, I would have the same reason for drawing the conclusion as regards a like

> complexity in the mental processes of the two…Jennings has not shown, nor has any one else shown that the behavior of lower organisms is objectively similar to that in man.
>
> ([10.14], 289–90)

But that is exactly what Descartes was saying!

To be sure, this does not signify that Watson was really a closet dualist. By 1913 he was arguing that we could eschew the use of 'all subjective terms' in human as well animal contexts (first-person cases included; see [10.15] and [10.17]). But what this parallel does reveal is that, whether or not there is a continuum of purposive reflexive behaviour has no bearing on the question of the criteria that license our judgment that our neighbour—or an animal—is conscious, intends to ϕ decided to Ψ believes, thinks, sees, feels ξ . At best it merely suggests the thesis that, should we all become familiar with this mechanist explanation of animal/human behaviour, the Cartesian might be forced into a much more extreme form of solipsism in which all human behaviour other than one's own would have to be treated on the same plane as animal.

What this means is that Descartes' attack on the Great Chain of Being is one that no amount of experiments on decerebrated frogs, hungry dogs, chimpanzees, blind interaction tests or learning programs can hope to resolve. This may sound a bizarre claim, given the three centuries of controversy devoted to the exact opposite premisses. Perhaps the reason for this anomaly is that Descartes himself was far from clear on the nature of his argument: is it *a priori* or *a posteriori, conceptual* or *empirical*? Hence, all the dissension over his motives in consigning animals to the realm of the mechanical. Many have suspected him of harbouring a hidden materialist agenda, while an equal number have accused him of devising his argument with the sole intention of thwarting such a development. But virtually all parties were agreed that Descartes launched a sceptical attack on the intelligence of animal behaviour which must be scientifically discredited if man's mental processes are to be understood: either by reinstating animals into the cognitive fold, or by redefining 'intelligent behaviour' so as to return man to his proper place among the natural order.

In what follows we shall be concerned with both the historical and the philosophical sides of this issue: viz., how Descartes' attack on the Great Chain of Being influenced the development of the mechanist picture of the continuum, and how, despite the mounting complexity of mechanist theories, culminating with AI, they have come no closer to refuting Descartes' attack on the continuum picture. But the goal here is neither to praise nor to bury Descartes. It is simply to understand the nature of his argument in order to understand the foundations upon which psychology has been built: to clarify the *type of theory* whereby

succeeding generations of mechanists, up to and including AI, have sought to free themselves from what they see as the Cartesian yoke that is stifling the science of mind.

II THE ANIMAL HEAT DEBATE

The philosopher of psychology's concern with the mechanist/vitalist debates sparked off by Descartes' attack on the Great Chain of Being is no mere exercise in the history of ideas and/or *Weltanschauungen*. That is not to deny the importance of this topic for the sociology of knowledge. But our immediate philosophical objective is to clarify the conceptual framework in which psychology has evolved, and equally important, the attitudes which we have inherited.

To be branded a vitalist is the ultimate in analytic invective: it is to be found guilty of allowing primitive metaphysical urges to overcome one's scientific rigour. No doubt there were countless country parsons and gentleman scholars who were attracted to vitalism because of their theological anxieties (just as there are many today who misguidedly believe that evolutionary theory has a bearing on the Creation myth). But no such charges could be laid against such scientists as Müller, Liebig or Bernard without grossly distorting their intentions, and thereby misconstruing the very essence of the issues with which they were concerned.

A proper treatment of the complex themes involved in the permutations of mechanist and vitalist thought would undertake to trace their history in light of the development of both the natural and the life sciences, and intimately connected with this, the shifting conceptions of man's nature and autonomy. But in so far as post-computational mechanism represents the culmination of nineteenth-century mathematical, physical, psychological and biological advances, there are strong grounds for confining our attention here to the mechanist/vitalist debates of that period. And yet, the very fact that the question from whence both schools proceed—viz., what is the difference between living and non-living matter?—had been a source of controversy for two millennia should surely give one pause; for much of what follows turns on the question of whether such an issue is to be resolved philosophically or physiologically. Or rather, it turns on the difference between a philosophical and a physiological approach to a question that is far from clear, nor constant in the succession of disputes which it has aroused.

The basic problem here is that philosophical and empirical questions should have been so closely intermingled in the two issues which dominated the period: the debates over the causes of an

animal's ability to maintain a state of thermal equilibrium, and the question whether reflex actions are in some sense purposive. Of course, on the scientistic conception of philosophy—the idea that, in Russell's words, 'those questions which are already capable of definite answers are placed in the sciences, while those only to which, at present, no definite answer can be given, remain to form the residue which is called philosophy' ([10.39], 70)—this is not a problem in the least; if anything, it is one of the primary catalysts for the scientistic outlook.[1]

The point is that the mechanist resolution of these two debates turned on the elimination of spurious a priori theories, which created a momentum that carried over into all remaining aspects of the mind/ body problem (as is epitomized, for example, in Russell's *The Analysis of Mind*). This is made clear in Section 3.4 of the *Vienna Circle Manifesto*. Here the overthrowal of vitalist theories in biology is equated with the imminent removal of similar 'metaphysical burdens and logical incongruities' from psychology ([10.36], 314). Thus, if we are to do justice to the scientistic conception of the mind/body problem—the gradual displacement of philosophical theories by psychological theories—we must address both aspects of the historical antecedents on which this view is based: i.e. vitalist as well as mechanist attitudes towards the nature of conceptual versus empirical problems.

It is not difficult to see what position Descartes must take on the above two issues. The whole thrust of his animal automaton thesis demands that he show how animal heat and movement can be explained without appeal to vital forces. Hence, he must show how, in animals, neither the production of heat nor bodily movements depend upon the activities of a soul (see [10.6], 329). In the *Discourse* he introduces his theory of heat as a paradigm for explaining all animal functions. ('[Understand this] and it will readily enable us to decide how we ought to think about all the others' [10.4], 134).) The heart, he argues, is like a furnace which produces its heat by a process similar to 'fires without light' (viz., spontaneous combustion or fermentation). This heat causes the blood entering the ventricles to expand and contract ('just as liquids generally do when they are poured drop by drop into some vessel which is very hot' (Ibid., 135)). Note that the reason why Descartes rejects Harvey's explanation of the contractile nature of the heart muscle is precisely because:

> if we suppose that the heart moves in the way Harvey describes, we must imagine some faculty which causes this movement; yet the nature of this faculty is much harder to conceive of than whatever Harvey purports to explain by invoking it.
>
> ([10.7], 318)

Here, Descartes claims, is an explanation that can be seen to follow from

> the mere arrangement of the parts of the heart (which can be seen with the naked eye), from the heat in the heart (which can be felt with the fingers), and from the nature of the blood (which can be known through observation). This movement follows just as necessarily as the movement of a clock follows from the force, position and shape of its counterweights and wheels.
>
> ([10.4], 136)

Yet few agreed with Descartes' hypothesis. To begin with, his 'fire without light' merely seemed to replace an enigma with a mystery. Second, the heart of a newly dissected animal did not feel as hot as Descartes' theory would suggest. Third, the argument overlooks the fact that the hearts of cold-blooded animals beat in the same way as those of warm-blooded animals. And fourth, the argument does not account for the ability of a warm-blooded animal to maintain a constant heat within a broad range of temperature extremes.

It was precisely in order to account for this last phenomenon that Barthez (re-)introduced the so-called *principio vitalis* in 1773, but in vastly different terms from what one finds in classical writings. Barthez postulated a 'special causal "principle of life", which was not to be confused with the origins of thought' ([10.27], II:87). He specified the 'role of the vital principle in digestion, circulation, the pulse, heat production, secretion, nutrition, respiration, the voice, genital function development, the senses, movement, sleep, perception' (Ibid.). In place of dualism, Barthez distinguished three separate elements: soul, body and vital principle, and thence two separate issues: the mind/body problem and the life/matter problem (Ibid., 89).

At stake for late eighteenth-century biology was the question of whether the so-called 'vital phenomena' were to be explained by special physiological laws or could be subsumed under the general laws of nature. The seventeenth-century search for a mechanical account of matter had obviously received a tremendous impetus from the Newtonian revolution: not simply because Newton had succeeded in presenting a unified account of the physical laws governing both the heavens and the earth, but had done so using concepts whose justification lay in their mathematical consistency and explanatory power. At one and the same time this was to have a profound effect on both mechanist and vitalist thought: the former because it would fix attention on the motion of matter, the latter because it would appear to license the use of 'forces' on a par with gravity to explain vital phenomena.

What was primarily an empirical problem concerning the location and generation of animal heat merged, during the nineteenth century, into a

philosophical debate on the mind/body problem, mainly because the amorphous notion of *vital phenomena* indiscriminately grouped together those biological processes which typify living organisms (e.g. reproduction, growth, respiration, metabolism) with the so-called 'psychic processes' experienced by man. To exclude the latter from the biochemical successes that were rapidly eliminating vitalist explanations from physiology seemed, as far as the scientific materialists were concerned, to abandon the mechanist spirit of the age in favour of dualist obscurantism. But we must be careful not to generalize on the basis of their example.

Several historians of science have warned of the dangers of over-simplifying the mechanist/vitalist debate during the nineteenth century. There are subtle but significant distinctions to be drawn between the scientific materialism espoused by Vogt, Moleschott and Büchner (see [10.26]), the reductionist materialism of the mechanist quadrumvirate (Brücke, Du Bois-Reymond, Helmholtz and Ludwig (see [10.21], [10.27])) and Liebig and Bernard's vital materialism (otherwise known as 'physical' or 'descriptive' materialism (see [10.41], [10.25], [10.32])). These differences were a consequence of the fact that the two prevailing theories of mechanism from the seventeenth century to the beginning of the nineteenth century—the physical and the physiological—not only seemed to be independent of one another, but if anything, in opposition to one another.

The former was the direct consequence of the search for the universal laws of nature. The latter saw man, animals and plant life as machines exhibiting a uniquely self-regulating behaviour. This was particularly true of that most quintessential feature of living organisms: their ability to maintain a constant heat (generally) above that of their surroundings, whereas inanimate matter rapidly tends towards thermal equilibrium with its environment. But despite the attention which this issue received, it proved impossible 'to bring a former "vital function", animal heat, into accord with the mechanical theories of heat so prominent in the years following Newton' ([10.34], 91).

The problem of animal heat is important in more ways than one for the foundations of psychology. Not only did it dominate the mechanist/vitalist debate up to the 1870s (cf. [10.33], 6–7), but as a direct result, created a focus which continues to influence critical attitudes towards psychology. This line of thought can be pursued in two different directions. One leads through Helmholtz's work on the conservation of energy to the debate on the second law of thermodynamics, the bearing which the kinetic theory of gas had on vitalist thought, and ultimately to the development of information theory. The reason why Helmholtz's work was so pivotal is partly because of his close relations to the Berlin

mechanists, and partly because of his unique position to bridge the physical and the physiological in the theory of heat, as is amply demonstrated by his publication in 1847 of 'Über die Erhaltung der Kraft' and 'Bericht über die Théorie der Physiologischen Wärmeerscheinungen' (see [10.24] and for a reminder of the number of participants involved [10.30]).

For present purposes, we shall concentrate on the consequences of the physico-chemical transformation of physiology. Although this set the stage for the unification of the two species of mechanism, it served in the process to sunder materialist thought. The problem was that animal heat was but one of the vital phenomena which had divided the two schools of mechanism. The Darwinian revolution encouraged a new generation of materialists to assume that the successes demonstrated in the physiological explanation of the theory of heat could be extended to the mechanisms governing growth and reproduction. But what of the host of problems contained under 'psychic processes', for example, conscious and unconscious mental processes, thought, intentions, volition, beliefs, reasoning, problem-solving, insight, memory, perception and sensation?

The answer to this last question lies partly in the changing attitude towards neurophysiology. At the beginning of the century Berzelius had portrayed the brain, not as the last frontier, but rather as inherently impenetrable. Hence, it was natural to respond to the 'Brodie hypothesis' (viz., that animal heat is in some way caused by the nervous system) with the vitalist dogma that the secret causes of animal heat would prove to be equally impenetrable (see [10.25], 98). The rapid development of experimental methodology and technology in physiological studies of respiration dating from the 1830s was matched, however, by a growing interest in anthropometry and the anatomy and pathology of the brain (cf. [10.20], 263–302).

The major breakthroughs which took place independently in both fields in the 1860s not only dealt a devastating blow to vitalist attitudes towards the problem of animal heat (and hence other biological vital phenomena), but also had a dramatic effect on mechanist attitudes towards the brain. While Liebig, Helmholtz and Bernard were successfully identifying the complex mechanisms involved in the organic conservation of energy, Broca, Fritsch, Hitzig and Wernicke were discovering (or at least, were seen as discovering) the neural localization of specific motor and language functions. Thus, it was increasingly tempting to conclude that what was relevant to homeostatic vital phenomena would apply no less forcefully to 'cerebral' vital phenomena. It was the assumption that any explanation of the nature and causes of psychic processes would have to be one which pursued the same lines as

the theory of heat which, more than anything else, divided late nineteenth-century materialist thought.

Just as Vogt, Moleschott and Büchner had deliberately distanced themselves from their mechanist predecessors, so, too, the reductionists were to repudiate what they regarded as the excesses of the scientific materialists. To be sure, there is considerable overlap between the writings of La Mettrie and the scientific materialists, if only because of the broad spectrum of activities grouped together under the notion of 'vital phenomena'. But, as even Lange concedes, there is also a marked discontinuity as a result of the revolutions occurring in biology, physiology and chemistry ([10.31], ii:240–1). And the exact same thing can be said of the relationship between the scientific materialists and the reductionist materialists. Although the two groups shared a strongly anti-dualist bias, they evinced very different temperaments and objectives.

Whereas the former saw themselves as popularizers and prosyletizers of a new ethos, the latter were first and foremost experimentalists intent on instituting new technological and methodological principles. For the reductionists, the dualist issue at stake was largely (if not exclusively) confined to the removal of 'vital forces' from biochemical explanations of physiological processes. But for the scientific materialists, this spilled over into mind/body dualism; there could be no categorial distinction between mental causes of animal heat and mental causes of behaviour. This resulted in what has proved the most memorable quotation from scientific materialist writings: Vogt's infamous remark that 'thoughts stand in the same relation to the brain as gall does to the liver or urine to the kidneys' ([10.26], 64).

Vogt may have been satisfied with the reaction which he clearly intended to provoke with this comment (which he did not in fact originate), but the other scientific materialists were far from pleased with the brouhaha that ensued. Büchner could not 'refrain from finding the comparison unsuitable and badly chosen'; thought 'is no excretion, but an activity or motion of the substances and material compounds grouped together in a definite manner in the brain' ([10.20], 303–4). Despite the variations which this theme was to undergo in materialist writings from Cabanis to Czolbe (see [10.35], 469–70), the basic point which remained constant is that cognition, *qua* 'mental' phenomenon, must permit the same type of causal explanation as any of the other biological vital phenomena. And it was ultimately this theme which led to the formal rupture between the two mechanist groups.

As far as the reductionists were concerned, this was to confuse philosophical speculation about an empirical problem with empirical speculation about a philosophical problem. The latent tension between them which was present from the start came to a head in 1872 when Du

Bois-Reymond insisted in his infamous lecture on 'The Limits of our Knowledge of Nature' that the real:

> faultiness with Vogt's expression…lies in this, that it leaves the impression on the mind that the soul's activity is in its own nature as intelligible from the structure of the brain, as is the secretion from the structure of a gland.
>
> ([10.22], 31–2; cf. [10.28], I, 102–3)

This led Du Bois-Reymond to close on a note that was to prove no less provocative: 'as regards the enigma what matter and force are, and how [the brain gives rise to thought, the scientist] must resign himself once for all to the far more difficult confession—"IGNORABIMUS!"' (Ibid., 32).

Du Bois-Reymond was not hereby abandoning, but was rather seeking to contain mechanism. His 'Ignorabimus' was putatively set by the bounds of materialism: i.e. what cannot be explained by 'the law of causality' (viz., the nature of matter, force and thought) cannot be explained at all. The argument was thus intended to circumscribe the parameters of the mechanist/vitalist debate.[2] Far from wishing to lend any support to the vitalist approach to 'psychic processes', his intention was rather to remove the latter from the scientist's legitimate concern with Vital forces' (Ibid., 24). In other words, the mechanist/vitalist debate is strictly confined to the life/matter problem; to conflate this with the mind/body problem is to confuse an empirical with a conceptual issue, which cannot but result in a materialist metaphysics. (Which in turn, as Du Bois-Reymond rightly anticipated, would give rise to idealist responses.) The only issue that involves the mechanist is that:

> What distinguishes living from dead matter, the plant and the animal, as considered only in its bodily functions, from the crystal, is just this: in the crystal the matter is in stable equilibrium, while a stream of matter pours through the organic being, and its matter is in a state of more or less perfect dynamic equilibrium, the balance being now positive, again approaching zero, and again negative.
>
> (Ibid., 23)

This argument draws heavily on Bernard's theory that 'All the vital mechanisms, varied as they are, have only one object, that of preserving constant the conditions of life in the internal environment' ([10.37], 224). This in turn had evolved from Liebig's 'state of equilibrium',[3] demonstrating yet again how difficult it can be to distinguish between the various schools; for Liebig is commonly identified as a vitalist, largely because he was prepared to countenance the presence of vital forces in physiological explanations.

According to Liebig, 'the state of equilibrium [is] determined by a resistance and the dynamics, of the vital force' ([10.25], 136). Like Barthez, however, he divorced this vital-causal agency from the mind/ body problem,[4] and justified its heuristic role by comparing it to the concept of gravity which, 'like light to one born blind, is a mere word, devoid of meaning'. In a passage in *Animal Chemistry* which clearly serves as a precursor for Du Bois-Reymond's 'Ignorabimus', Liebig explicitly drew on the methodological precedent established by gravity in order to defend the explanatory role which vital forces play in physiology:

> Natural science has fixed limits which cannot be passed; and it must always be borne in mind that, with all our discoveries, we shall never know what light, electricity, and magnetism are in their essence, because even of those things which are material, the human intellect has only conceptions. We can ascertain, however, the laws which regulate their motion and rest, because these are manifested in phenomena. In a like manner, the laws of vitality, and of all that disturbs, promotes, or alters it, may certainly be discovered although we shall never learn what life is. Thus the discovery of the laws of gravitation and of the planetary motions led to an entirely new conception of the cause of these phenomena.
>
> ([10.25], 138)

Similarly, Bernard emphasized 'the vital point of view' in contrast to those scientific materialists who 'paid too much attention to the purely physical side of nervous and muscular action' ([10.37], 149). And like Liebig, he maintained that, 'When a physiologist calls in vital force or life he does not see it; he merely pronounces a word' ([10.25], 151). Bernard was careful, however, to chastise those who would invoke 'a vital force in opposition to physicochemical forces, dominating all the phenomena of life, subjecting them to entirely separate laws, and making the organism an organized whole which the experimenter may not touch without destroying the quality of life itself' ([10.37], 132–3). And yet, contemporary physiologists saw in Bernard's *directive idée* which governs the activities of the *milieu intérieure* a return to just such a vitalist position.[5]

To historians of science, the real question which these 'mere words, devoid of meaning' raises is not so much whether Liebig and Bernard's theories should be classified as vitalist or mechanist, as whether they signal the imminent demise of the mechanist/vitalist debate as far as the problem of animal heat was concerned (see [10.32]; [10.21]). Bernard sought to distinguish between organic and inorganic processes without postulating the existence of special laws or kinds of

matter to explain the former ([10.25], 158–60; [10.32], 457). The mechanical laws of heat are indeed universal, but 'life cannot be wholly elucidated by the physico-chemical phenomena known in inorganic nature'. But while there are Vital phenomena [which] differ from those of inorganic bodies in complexity and appearance, this difference obtains only by virtue of determined or determinable conditions proper to themselves' ([10.25], 151). That is, the explanation of these unique biological processes must conform to established 'scientific method': i.e. to the laws of causality.

In an obvious sense this had done nothing to eliminate the core of the mechanist/vitalist debate; rather, its decline *vis-à-vis* the life sciences is to be sought on the sociological, not philosophical grounds that 'Ultimately vitalism disappeared with the emergence of a new set of questions' (Ibid.) in much the same way and at much the same time that

> Physical research had been diverted…into an entirely new channel. Under the overmastering influence of Helmholtz's discovery of the conservation of energy, its object was henceforward to refer all phenomena in last resort to the laws which govern the transformations of energy.
>
> ([10.29], 46)

Once again we must be careful not to oversimplify the situation. Given the diversity of processes grouped together under 'vital phenomena', the mechanist/vitalist debate was far from curtailed by this development: what occurred was rather a significant realignment in its focus. Animal heat was now relegated to the secondary status of a subsidiary metabolic activity. What took its place as far as the controversy over a 'life force' was concerned was the controlling agency overseeing the various homeostatic mechanisms that sustain life.

The theory of animal heat had left its mark, however; for the very nature of the problem invited the model of a self-regulating system which, as Arbib points out, was instrumental in the evolution of the notions of control mechanism and intelligent automata ([10.18], 80–1). It is thus no coincidence that the thermostat should have come to play such a central role in the elucidation of cybernetics. When Liebig first articulated the principle that all matter is governed by the same thermal laws, he used the example of food and oxygen as the fuel which enable the animal/furnace to maintain a stable temperature. It is also interesting to note that in 1851 Helmholtz and Du Bois-Reymond simultaneously (and independently) compared the nervous system to a telegraph system 'which in an instant transmit[s] intelligence from the outposts to the controlling centres, and then convey[s] its orders back to the outlying

posts to be executed there' ([10.29], 72; see Helmholtz's remark about Wagner (Ibid., 87) and Du Bois-Reymond's letters ([10.23], 64)).

This proto-cybernetic picture provided the obvious starting-point for a new generation of mechanists who were eager to respond to the furore provoked by Darwin and, even more importantly, the renewed vitalist attack inspired by Du Bois-Reymond. For Du Bois-Reymond's lectures offered an opportunity which no vitalist was likely to forgo, and a challenge which no mechanist could afford to ignore. Yet another reading of Du Bois-Reymond's *ignorabimus*, therefore, is that while it marked the end of the physiologist's biochemical involvement in the physical/physiological thermal debate, the very terms in which he presented his argument served notice that the issue was shifting to a different arena: one in which physiologists and psychologists would do battle with philosophers over the structure of those teleological and 'psychic' processes which Du Bois-Reymond had dogmatically declared out of materialist bounds.

III THE REFLEX THEORY DEBATE

The debate over the theory of heat established a paradigm for the scientistic outlook. Here was a case where conceptual progress, made possible by technological advances, had enabled scientists to eschew any appeal to 'logical fictions'. The movement in this issue was from the study to the laboratory, as a question in which philosophers had originally played a leading role was ultimately removed altogether from their sphere of influence. Unlike the case of animal heat, however, the philosophical problem in the debate over reflex actions concerns the question whether it *makes any sense* to suppose that these underlying neural processes could explain the nature of purposive behaviour.

At first sight the debate over reflex actions appears to be—or at least was conceived by Descartes to be—of exactly the same order as that over the theory of heat. Behaviourists, and indeed cognitivists, have cast themselves in much the same role as the mechanist reductionists. The whole point of the so-called top-down/bottom-up distinction is to suggest that, as with the case of animal heat, it would be possible to resolve this problem experimentally if only we had sufficient 'information about the physiological states of the *twelve billion neurons* in the human brain, each with up to *five thousand* synapses' ([10.44], 476). But at our present level of understanding:

> This vast amount of information and its fantastic complexity would utterly dumbfound us; we could not hope to begin creating much order out of such vast quantities of particulate information.

> Rather, we would need some very powerful theories or ideas about how the particulate information was to be organized into a hierarchy of higher-level concepts referring to structure and function.

Hence:

> Many psychologists feel that their task is to describe the functional program of the brain at the level of flow-charting information-processing mechanisms. What is important is the logical system of interacting parts—the model—and not the specific details of the machinery that might actually embody it in the nervous system.
>
> (Ibid.)

No better example of the paramount role which the Cartesian framework plays in the evolution and the continuity of mechanist thought can be found than in the persisting mechanist preoccupation with the nature of purposive behaviour. Goals and intentions are more than just an embarrassment for the mechanist thesis. They have become the testing ground which decides the success or failure of entire theories.

The roots of this fixation lie in Descartes' attempt to explain reflex actions in such a way as to encompass all animal behaviour, while excluding a significant portion of human behaviour. According to Descartes, a reflex action is the result of the automatic or machine-like release of animal spirits that are stored in the brain: a point which applies to all reflex movements, whether these be animal or human. But humans, unlike animals, are endowed with a mind that is able to modify the reflection of animal spirits in the pineal gland, thereby resulting in voluntary or conscious actions.

The obvious response for the vitalist champion of the Great Chain of Being to make to this argument was to establish that animals are at least capable of purposive behaviour (or, on the extremist position, that *all* animal behaviour is purposive). There was another option available to the defender of the continuum picture, however, which was certainly not conceivable before Descartes: viz., that all human, as well as all animal behaviour, is automatic, albeit governed by mechanisms that might be vastly more complex than those which occur in simpler life forms. And given the reductionism which defined eighteenth- and nineteenth-century materialism, it was only natural to present this 'mechanist thesis' in the same terms as applied in the animal heat debate, with 'goals', 'purposes', 'intentions' and 'volitions' dismissed as akin to 'vital forces'.

What makes this issue so difficult is that there is an important parallel to be drawn between the debates over animal heat and reflex actions: viz.,

both were first and foremost biological problems riddled by a priori preconceptions which led into philosophical concerns over the mind/body problem. As we saw in section 1, at the heart of Descartes' attack on the Great Chain of Being is his idea that the subject is conscious of the operations of his mind: of his cognitions, perceptions, sensations, imaginings and affects. We experience these 'actions of the soul', or, in more general terms, 'volitions', as 'proceeding directly from our soul and as seeming to depend on it alone' ([10.6], 335). But although immediately acquainted with the 'actions of our souls', we are not conscious of the intervening mechanisms involved in the bodily movements brought about by our volitions (i.e. the mechanisms activated by the animal spirits that are released when the soul deflects the pineal gland). That does not mean that the processes involved in the maintenance of body heat and in bodily movement are *unconscious,* however; rather, they are *non-conscious*. For to suppose that they might be 'unconscious' would imply that these processes take place beneath the threshold of an animal's—as well as man's—consciousness (where Descartes has already excluded the former possibility a priori).

What we have to remember in the reflex theory debate is that almost everyone was opposed to Descartes' attack on the Great Chain of Being, but not to his presupposition that all actions are the effects of causes. Thus the burden which Descartes' argument imposed on vitalists and mechanists alike was to establish that man and animals are equally capable of purposive behaviour: in significantly different senses. In the case of vitalists, this meant showing how the mental causes of purposive behaviour are shared by animals; for mechanists, that whatever is responsible for the 'purposiveness' of human 'voluntary' behaviour is a feature that is also present in animal movements.

Both sides were agreed, therefore, that the 'purposiveness' of purposive behaviour must lie in the *originating causes* of that behaviour, not in the actual movements of that behaviour. This means that there is nothing in the movements of purposive behaviour to account for the purposiveness of that behaviour; we can at best *infer,* not *observe* that that behaviour is purposive (has such-and-such a cause). Yet, both sides were also (tacitly) agreed that the purposiveness of purposive behaviour must be evident in the behaviour; otherwise, it would make no sense to distinguish between 'purposive' and 'non-purposive' behaviour, and without such a distinction, no sense to speak of 'purposive' behaviour. Hence our 'inability' to observe someone else's, or an animal's, 'originating causes'—either because of the intrinsic privacy of minds (in which case our 'inability' is a priori) or because these causes are neural (in which case our 'inability' is what Russell called 'medical')—has no bearing on the classification of someone or something's behaviour as purposive.

Furthermore, both sides were committed to demonstrating that the various bodily movements which Descartes had identified as reflexes are in fact purposive: again, for vastly different reasons. As far as the vitalists were concerned, this was solely in order to establish that these movements are not mechanical, i.e. that, as Stahl put it, 'the very purposiveness of the so-called "reflex actions" proves that, even if we are unaware of the fact, the soul controls all bodily movements' (see [10.27], ch. 25). For mechanists, the challenge was to show that to describe a reflex action as purposive in no way entails that it must have been brought about by the 'actions of a soul'; i.e. that animals and perhaps even plants are capable of such movements. But before the implications of this issue for dualism could be properly addressed, it was first necessary to confirm that reflex actions are indeed purposive, and to do that required an understanding of the mechanics of automatic behaviour.

Descartes' views had a profound impact on the seventeenth-century conflict between iatro-physicists and iatro-chemists on the life/ matter issue. What had hitherto been regarded as a debate over the universality of the laws of mechanics (the question whether the operations of the body are subsumed under the laws of physics, or call for special chemical laws) was now forced to account for the similarities and/or differences between plant, animal, and human 'responses to stimuli'. The emerging consensus accepted a sharp division between the behaviour of living and non-living matter, but as far as the continuity of animal and human life forms was concerned, most 'true philosophers' agreed that 'The transition from animals to man is not violent' ([10.10], 103).

Both sides in this transformed mechanist/vitalist debate accepted that Descartes was wrong, but for vastly different reasons. Apart, that is, from the question of Descartes' remarks on anatomy, which virtually everyone saw as antiquated. The mechanists were of course disturbed by Descartes' commitment to a metaphysical soul; the vitalists by the suggestion that a large element of human and animal behaviour is automatic.

The conflict between the two sides centred on three key problems with Descartes' argument. First, the dubious role assigned to 'animal spirits'. As Stensen put it, 'Animal spirits, the more subtle part of the blood, the vapour of blood, and juice of the nerves, these are names used by man, but they are mere words, meaning nothing' (quoted in [10.45], 8). Second, there was the fact that decerebrated animals can continue to move, which was difficult to reconcile with Descartes' premiss that animal spirits are stored in the brain. And third, the fact that animals are capable of adapting to their environments, which was

difficult to reconcile with the seventeenth-century conception of 'machine'.

This last point became the focus of attention throughout the eighteenth century. Vitalist attitudes are summed up by Claude Perrault's belief that:

> although the movements of plants in turning towards the sun, and the flowing of the river which 'seems to seek the valley', appear to indicate choice and desire, in reality these movements are of a wholly different nature than those of animals. In the latter there is a soul which is concerned with sensation and movement.
>
> ([10.47], 33)

The exact same issue—the overriding concern with the mechanics of 'choice and desire'—recurs throughout the ensuing debates over mechanism (and indeed, lie at the heart of Turing's thesis[6] (see [10.55])).

The crux of the vitalist position was that, in the words of Samuel Farr, the body is more than 'a simple machine, instigated by no spiritual agent, and influenced by no stimulus'. Even if 'custom and habit[7]' should have made us oblivious of the fact, all movements—voluntary and involuntary—are 'controlled by the wil' ([10.47], 102). The proof lay in the dogmatic *modus tollens* that, if the body were a machine, its movements could not *per definiens* be purposive; but since the latter is patently false, so too must be the premiss. This is the reasoning underlying Alexander Monro the younger's assertion that, 'The more we consider the various spontaneous operations the more fully we shall be convinced that they are the best calculated for the preservation and well-being of the animal' (Ibid., 106). Hence Stahl's conclusion that:

> Vital activities, vital movements, cannot, as some recent crude speculations suppose, have any real likeness to such movements as, in an ordinary way depend on the material condition of a body and take place without any direct use or end or aim.
>
> (Ibid., 32–3)

The mechanist response to this argument received a major boost from Hartley's *Observations on Man*. The strength of Hartley's argument lay in the manner in which he turned a central theme in vitalist thought to mechanist advantage. Perrault and Leibniz had argued that there are two different kinds of movement under the control of the soul: those that are consciously dictated, and those which through habit no longer require an act of choice for their performance, and have thus become unconscious (see [10.47], 33). This, too, is an issue which has remained at the forefront of post-computational mechanist concerns. What is particularly

interesting, when tracing the continuity in mechanist thought on the problem of insight, is to locate the origin of Newell and Simon's models of the mechanics of 'pre-conscious selection' in Hartley's account 'Of muscular Motion, and its two Kinds, automatic and voluntary; and of the Use of the Doctrines of Vibrations and Association', for explaining these respectively ([10.50], 85; see [10.54]).

According to Hartley, voluntary movements are brought about by ideas, automatic movements by sensations. Sensations are caused by the vibration of minute particles in the nerves which ascend to the brain where, if repeated a sufficient number of times, frame an image or copy of themselves. These images, or 'simple ideas of sensation', constitute the building material for complex ideas. Images of regularly occurring sensory vibrations can also form in the nerves. These 'vibratiuncles' are 'the physiological counterparts of ideas'. This yields Hartley's famous (isomorphic) laws of association: any sensation/vibration A,B,C, by being associated with one another a sufficient number of times, get such a power over corresponding ideas/vibratiuncles a,b,c that any one of the sensations/vibrations A, when impressed alone, shall be able to excite in the mind/brain b,c the ideas/vibratiuncles of the rest.

Although prepared to describe himself as a mechanist, Hartley was no determinist. The problem posed by his argument was simply that, while voluntary actions are caused by ideas, the latter are themselves the product of experience. (The price he pays for free will is an unconvincing defence of a Cartesian soul that is able to originate causes of actions.) As far as the evolution of mechanism is concerned, the significance of his emphasis on the role of past experience is twofold: first, it opened up the prospect of a scientific study of the laws governing the succession of thoughts; and second, it suggested a method of breaking down the barrier between voluntary and involuntary movements.

On Hartley's account, what were originally voluntary motions can become automatic, and vice versa: 'Association not only converts automatic actions into voluntary, but voluntary ones into automatic' ([10.47], 85). To illustrate the former phenomenon, Hartley cites the example of a baby automatically grasping a rattle:

> after a sufficient repetition of the proper associations, the sound of the words *grasp, take, hold,* etc., the sight of the nurse's hand in a state of contraction, the idea of a hand, and particularly of the child's own hand, in that state, and innumerable other associated circumstances, i.e. sensations, ideas, and motions, will put the child upon grasping, till, at last, that idea, or state of mind which we may call the will to grasp, is generated, and sufficiently associated

> with the action to produce it instantaneously. It is therefore perfectly voluntary in this case.
>
> ([10.42], 94)

Here is an explanation of what, in the early twentieth century, would be referred to as the 'stamping in' of volitions. To illustrate this phenomenon, Hartley offers the example (now familiar in cognitivist writings) of someone learning how to play the harpsichord: at the beginning he exercises 'a perfectly voluntary command over his fingers', but with time 'the action of volition grow[s] less and less express…till at last [it] become[s] evanescent and imperceptible' ([10.47], 85).

Hartley made clear that his paramount intention in this argument was to restore the continuum picture. An entire section is devoted to showing how 'If the Doctrines of Vibrations and Association be found sufficient to solve the Phenomena of Sensation, Motion, Ideas, and Affections, in Men, it will be reasonable to suppose, that they will also be sufficient to solve the analogous Phænomena in Brutes' ([10.50], 404). He even went so far as to claim that 'the Laws of Vibrations and Association may be as universal in respect of the nervous Systems of Animals of all Kinds, as the Law of Circulation is with respect to the System of the Heart and Blood-vessels' (Ibid.).

The impetus for this latter argument lay in the fact that eighteenth-century vitalists had based their objection to mechanism on the classical Newtonian exclusion of teleological considerations from mechanical explanations. This had placed the onus on mechanists to account for the organization, adaptativeness and directedness of 'spontaneous movements' in strictly physical terms. And that is exactly what remains most problematic in Hartley's argument; for Hartley had remained enough of a Cartesian to see the progression from voluntary to secondarily automatic actions as the movement from actions caused by volitions to those instigated by mechanical causes (as is brought out by his use of the term 'secondarily *automatic*'). But then, this does nothing to counter the terms of Descartes' attack on the Great Chain of Being, since the objection still remains that behaviour bifurcates into mechanical and volitional.

Fortunately for mechanists, the apparent key to removing the latter obstacle was to be provided, two years after the publication of *Observations on Man,* by Hartley's vitalist peer, Robert Whytt. The central theme in Hartley's account of involuntary movement is given the same prominence in *An Essay on the Vital and other Involuntary Motions of Animals*. Indeed, not only does Whytt emphasize the importance of involuntary actions which we 'acquire through custom and habit,' but he does so using the same example as Hartley. In standard vitalist fashion, Whytt insists that such 'automatic actions' are not mechanical. Hence he

warns that the term 'automatic' is dangerously misleading, since 'it may seem to convey the *idea* of a mere inanimate machine, producing such motions purely by virtue of its mechanical construction' (Ibid., 75). But unlike earlier vitalists, Whytt was not suggesting that all purposive movements must *ipso facto* be under the direct control of the will. Rather, these automatic actions-whether reflex or secondarily automatic—are controlled by a 'sentient principle' which is co-extensive with the mind but is below the threshold of consciousness, and can thus be neither volitional nor rational.

This third type of causal factor enables Whytt to complete the anti-Cartesian attack which eluded Hartley. The key to defending the continuum picture was to define a continuum of voluntary and involuntary actions. Hartley could only speak of actions 'esteemed less and less voluntary, semi-voluntary, or scarce voluntary at all' (Ibid., 84). For the orthodox Cartesian, this would mark the break-off point between human and animal behaviour. But Whytt could superimpose on this a continuum of animal and human sentient behaviour. It is precisely on this basis that we find Whytt emphasizing how:

> It appears, that as in all the works of nature, there is a beautiful gradation, and a kind of link, as it were, betwixt each species of animals, the lowest of the immediately superior class, different little from the highest in the next succeeding order; so in the motions of animals…the mix'd motion, as they are called, and those from habit, being the link between the voluntary and involuntary motions.
>
> (Ibid.)

By thus extending reflex theory to encompass both voluntary and involuntary movements in such a way as to have the one shade into the other, Hartley and Whytt had paved the way for what would henceforth be seen by mechanists as the continuum of unconscious/ conscious purposive behaviour: not just in man, but throughout the chain of self-regulating life forms. Not the perfect continuum demanded by the *scala naturae,* however; rather, a continuum made up of a myriad different branches (as would, of course, become the primary picture at the end of the nineteenth century with Darwin's tree metaphor).

This provides the (barest fragment of the) background to Marshall Hall's controversial claim at the beginning of the nineteenth century that reflex actions are 'independent of both volition and sensation, of their organ the brain, and of the mind or soul' ([10.47], 139)- Hall's model was highly schematic, leading Sherrington to warn at the end of the century that 'there are a number of reactions that lie intermediate between [Hall's] extreme types, "unconscious reflex" and "willed action"' (Ibid., 140). A

large part of the experimental progress made over the century was stimulated by the obvious need to fill in these lacunae. But even more important, for philosophical purposes, are the misleading terms in which Sherrington described Hall's contribution. In the above quotation Hall stresses that reflex actions take place 'independent of both volition and sensation'. Had he described these movements as 'unconscious', it would certainly not have been in the sense which Pflüger understood when he criticized Hall's theory, nor that which Lotze intended when he responded to Pflüger's attack on Hall *(infra)*.

The use of the term 'unconscious' is a source of endless confusion when discussing the reflex theory debate; for it is indiscriminately applied to those who held that consciousness plays no causal role in involuntary movements and those who insisted that all purposive behaviour must—by definition—be under the control of a 'degenerated will'.[8] Furthermore, we must distinguish within the former category between those who held that it makes no sense to speak of a creature or agent being aware of mechanically responding to a stimulus, and those who regarded reflex and secondarily automatic movements as unconscious sentient reactions. Thus, we must distinguish between two concurrent mechanist/vitalist debates on reflex theory in the nineteenth century: one over the question whether purposive automatic acts are mechanical or sentient, and the other whether the very notion of a *purposive automatic act* is a contradiction in terms.

Bearing in mind its Cartesian antecedents, it is not quite so curious that this issue should have been fought out over the question whether the reflexes of decerebrated animals are voluntary, and thus—contra Hall—under psychic control. In the Pflüger-Lotze version of this debate, the issue was largely confined to the question of whether the reflex movements of a decerebrated frog are conscious. As far as Pflüger was concerned, the very fact that a decerebrated frog can shift from its favoured leg to the other limb in order to remove acid placed on its back renders it self-evident that its actions are intelligent, and hence, that consciousness is co-extensive with the entire nervous system. Lotze's objection to this 'spinal soul' theory turned on the familiar theme that what appear to be voluntary actions are in fact secondarily automatic motions, resulting from originally intelligent actions that were stamped into the frog's brain by previous experiences.[9] In order to constitute genuinely intelligent action, we would need proof that the frog is capable of responding to demonstrably novel circumstances.

Both sides were agreed, however, that such movements are legitimately described as 'purposive': a premise from which much of the confusion sustaining the mechanist/vitalist debate was to follow. Moreover, the very terms of this conflict ensured that such confusion was to follow. For to agree with Pflüger was to concede the applicability of

volitional concepts to spinal reflexes, whereas to side with Lotze was to accept, not merely that such movements can be described as 'unconscious' (in the sense that originally mental causes have become automatic), but equally serious, that learning is a form of neurological imprinting.

Boring dismissed this whole controversy as nothing more than a squabble over whether to 'define consciousness so as to exclude spinal reflexes or to include them' ([10.43], 38). Were this simply a dispute over semantic proprieties this issue would now belong to the history of psychological ideas, not philosophy. But this is not at all the pseudo-problem which Boring contended. For the problem was not just concerned with the boundaries of the concept of consciousness: more importantly, it was a debate over the *causes* of the behaviour that had been so delimited (as well, of course, as a debate over the 'nature and location' of consciousness).

From a modern perspective, perhaps the most striking feature of the reflex theory debate is that, the more physiologists began to understand the mechanics of the autonomic nervous system, the more prominent became philosophers' interest in Descartes' attack on the continuum picture. One reason for this reaction was their mounting concern over the determinist implications which scientific materialists were drawing from reflex theory (as is evident, for example, in the writings of Mill, Green, Sedgewick and Spencer). Thus, we find Carpenter insisting in *Principles of Mental Physiology* ([10.46]) that what mechanists had ignored in their quest to 'elucidate the mechanism of Automatic action' were

> the fundamental facts of Consciousness on which Descartes himself built up his philosophical fabric, dwelling exclusively on Physical action as the only thing with which Science has to do, and repudiating the doctrine (based on the universal experience of mankind) that the Mental states which we call Volitions and Emotions have a causative relation to Bodily changes.
>
> ([10.47],

Well into this century we encounter Descartes' argument for 'semisolipsism', but with one notable difference: gone is any hint of Descartes' consequent attack on the continuum picture. Herrick, for example, explains in *Neurological Foundations of Animal Behavior* (1924) that:

> Consciousness, then, is a factor in behavior, a real cause of human conduct, and probably to some extent in that of other animals… This series of activities as viewed objectively forms an unbroken graded series from the lowest to the highest animal species. And

> since in myself the awareness of the reaction is an integral part of it, I am justified in extending the belief in the participation of consciousness to other men and to brutes in so far as the similarities of their objective behavior justify the inference.
>
> ([10.47], 179)

This overturning of Descartes' intentions was based on an argument which one finds in such self-styled defenders of Descartes' 'animal automata' thesis as Lewes and Huxley: viz., the doctrine that animals, and indeed man, are 'sentient automata' (see [10.51]).[10]

What these neo-Cartesians thought they were doing was correcting an empirical oversight on Descartes' part on the basis of the two centuries of physiological advances that had intervened. They proposed to replace Descartes' *mechanical* distinction between conscious/voluntary and non-conscious/involuntary movements with a *sentient* distinction between conscious/voluntary and unconscious/involuntary movements. The major benefit of this strategy is that it enabled them to reconcile the existence of volitions with the continuum picture, and thus, remain in step with the dawning Darwinian revolution.[11]

This does not mean, however, that they were about to anthropomorphize animals by assigning them voluntary acts as defined by Descartes. The 'similarities of objective behaviour' between animals and man lay rather at the level of sentient—equals unconscious or automatic—reactions. This leads one to suspect that perhaps the real point which Boring was driving at was that this controversy was not so much over the definition of 'consciousnes' as over the definition of 'machine'. For both sides of the mechanical/sentient debate were committed to a mechanist framework which was to survive the particulars of the Pflüger-Lotze dispute.

According to the vitalist outlook, secondarily automatic actions are the result of neural mechanisms that had been imprinted in the frog's cerebrum. When the animal was first undergoing these experiences it might have been conscious of its sensations; but consciousness, on this model, is deprived of any causal agency suggested by its inclusion in the group of 'vital phenomena', and reduced to the role of passive bystander.[12] In which case, should this behaviour become habitual, there is no reason to retain this 'ghost in the machine' in order to account for its residual purposive character.

On this argument, the difference 'between conscious, sub-conscious, and unconscious states…is only of degree of complication in the neural processes' ([10.52], 407). That is, consciousness is an *emergent property,* and 'There is no real and essential distinction between voluntary and involuntary actions. They all spring from Sensibility. They are all

determined by feeling' (Ibid., 420-2). The purposiveness of the behaviour exhibited by decerebrated animals results from the fact that 'sensations excite other sensations'. But while such movements may not be 'stimulated by cerebral incitations, and cannot be regulated or controlled by such incitations—or as the psychologists would say, because Consciousness in the form of Will is no agent prompting and regulating such actions'—they nonetheless 'have the general character of sentient actions' (Ibid., 416). Hence, the flaw in the mechanist argument lies in the fact that reflex acts are 'consentient' and for that reason 'not *physical* but *vital*' (Ibid., 366).

Mechanists were quick to point out that the only rationale for this use of 'vital' is that the laws governing the mechanics of unconscious purposive behaviour are biological rather than physical; and the mechanical sense of 'cause' which underpins this objection was already being replaced by a new conception that could embrace both types of phenomena. But what is perhaps most significant in the reflex theory debate as it stood at the end of the century is the mechanist use of 'unconscious'. Far from considering what it would mean to attribute consciousness to an intact—much less a decerebrated—frog, this was accepted as a question about the 'divisibilit' of consciousness. Certainly no one ever considered what sort of actions would license the assertion that these mutilated creatures were conscious or unconscious.[13]

What is not at first clear is why mechanists should have allowed themselves to be coerced into this position, rather than making the entirely sound point (which seems to have been Hall's original intention) that it makes no sense to describe such behaviour in terms of either the presence or suspension of consciousness. To characterize such movements as either *unconscious* or *involuntary* presupposes the logical possibility of consciousness or volition. But that was the last thing that mechanists wanted to suggest: for reasons which had nothing to do with considerations about the rules governing the application of the concepts of consciousness and unconsciousness. Rather, the whole thrust of the mechanist thesis had derived from the pressure to explain how 'purposive actions may take place, without the intervention of consciousness or volition, or even contrary to the latter' ([10.51], 218).

As would soon become apparent, the key word in this passage was 'intervention'. For there was no reason why mechanists should object to epiphenomenalism. Their quarrel was solely with the dualist notion of 'psychic directedness' to account for automatic motions. Thus, as far as the mechanist/vitalist debate over the nature of automatic acts was concerned, this was soon to become a dispute in name only. But then, why not extend exactly the same strategy to the remaining pillar of the vitalist argument: why eschew volitions when all you need to do is redefine them?

Thus it was that from one confused debate was born another. The problem was that all were agreed that the frog was trying to remove the acid placed on its back. But it is not at all clear what it means to speak of a creature trying to accomplish some goal of which it is not—*and could not be*—aware. Nor does it make any sense to suppose that we can at best 'infer' whether such a disfigured creature is or is not aware of a pain sensation and is trying to alleviate its discomfort. This very assumption is a reminder of the Cartesian origins of this debate: of the premiss that it is only our inability to observe the frog's mind (or at least, what was left of it!) which prevents us from resolving this issue.

Our judgements of a frog's sentience or its intentions are based on the rules governing the use of the concepts of consciousness and intention: rules which are grounded in the paradigm of human behaviour. In so far as human beings serve as the paradigm subjects for our use of psychological concepts, any question about the application of these concepts to lower organisms demands that we compare the behaviour of such creatures with the relevant human behaviour which underpins our use of that concept. For example, it is the complexity of the behaviour displayed by an organism which determines whether or not there are sufficient grounds for the attribution of a perceptual faculty. Thus, in order to establish that *Porthesia chrysorrhoea* can *perceive* light, Jacques Loeb had to show, not just that they react to certain stimuli, but that they are able to *discern* various features of their environment, i.e. that these caterpillars are able to employ what is in fact a *perceptual organ* to acquire knowledge about their environment. Otherwise the relevant concept here is not *perception* but rather, what Loeb so aptly described as a 'heliotropic mechanism' (see Section 4 below).

The corollary of this argument is that only of the caterpillar itself would it make sense to say that it 'perceives': not its 'photo-receptive organ' (or, in the case of the Pflüger—Lotze debate, the frog's central nervous system). The same holds true whether we are talking of more complex sensori-motor structures and perceptual organs, or indeed, the 'mind', 'soul' or 'consciousness'. For in none of these cases does it make sense to say that the organ or faculty in question demonstrates its ability to discriminate features of its environment. The rule of logical grammar rendering such a usage meaningless is that, only of the organism as a whole does it make sense to apply our psychological and cognitive concepts.[14]

It was only their preoccupation with salvaging the continuum picture which prevented the various mechanist and vitalist protagonists from realizing from the start just how curious were the questions which had inspired their bizarre debate.[15] It was this common nineteenth-century priority which led them to assume that the difference between sensori-motor

excitation, sensations, and perceptions is itself one of degree rather than of kind. But the difference between these three concepts is categorial, not quantitative. Hence, the source of the mechanist version of the continuum picture lay in the distortions which resulted from this illicit attempt to relate the concept of sensation to that of perception on a scale of neural complexity rather than discerning the logico-grammatical distinctions operating here.

There are indeed important lessons to be learnt from this debate: lessons about the application of psychological as well as physiological concepts. Mechanists were quite right to argue that, from the premiss that I can be unconscious of responding to a stimulus, it does not follow that that response was volitional. But exactly the same holds true if I am conscious of an automatic response to a stimulus. Conversely, I can respond mechanically to some signal (e.g. a conversational cue), but it does not follow that my response was determined by a causal mechanism. If my response to a stimulus was 'willed' (e.g. I stifle a yawn), then it was not a reflex. And if this behaviour should become habitual, then it is no longer willed.

Are these empirical observations? A similar question arises with respect to the Pflüger-Lotze debate. What Pflüger's experiments tell us is not that the frog was unconsciously trying to remove the acid placed on its back, but that we must be careful of how we apply the same concepts to a normal frog. For just as the decerebrated frog was neither *responding unconsciously* to a stimulus nor *trying* to remove the acid, so we have to reconsider what it means to say of an ordinary frog that it was *consciously trying* to remove acid placed on its back.[16] (Consider the experiments on the signal detectors in a frog's eye which are activated by any movement at the periphery of its visual field, and not just that of a fly.) That is not to say that we could never attribute such a psychological capacity to a frog but only, that experiments such as those performed by Pflüger and Goltz remind us of the defeasibility of our judgements of animal behaviour, i.e. force us to register the difference between instincts or reflexes and actions.

It was only by treating the categorial distinctions between sensorimotor excitation, sensations and perceptions as gradations on the scale of consciousness that the way was then open to regarding purposive behaviour as an ascending causal mechanism in which the relations to intentions and learning are rendered external rather than internal, and adaptation is misconstrued as a cognitive process. But there is no evolutionary continuum of purposeful behaviour such that, e.g. the contraction of the pupil of the eye belongs to the same category as striving for a goal; for the former is not a more 'primitive' form of purposive behaviour but rather, a reflex movement *as opposed to* purposive behaviour.

With the growing interest in comparative psychology which resulted from the Darwinian revolution, and the emphasis on evolutionary associationism that accompanied this, it was natural for mechanists to proceed from the opposite direction. Thus, it was held that consciousness and volition develop by degrees, and that the resemblance between the behaviour of a decerebrated frog and that of man is not and could not be expected to be pronounced. Rather, the correspondence lies at the sub-behavioural level: in particular, at the neurological structure where associations between sensations are imprinted. But then, such an argument only makes sense against the premiss that this mechanism is that which guides purposive behaviour *simpliciter,* and to *assume* that the reactions of a lower organism are purposive is to presuppose all of the foregoing argument. As indeed it must, for only of a human being and what resembles (behaves like) a human being can one say: it behaves in a purposive manner. Thus the crucial issue which such an argument overlooks is the need to explain in what sense such causal reactions can be termed purposive. And this was an omission which beset both sides of this mechanist/vitalist debate; or rather, a product of the Cartesian framework which governed their outlooks, and those who were about to follow in their footsteps.

IV THE RISE OF A 'NEW OBJECTIVE TERMINOLOGY'

Lewes once observed that:

> We can conceive an automaton dog that would bark at the presence of a beggar, but not an automaton dog that would bark one day at a beggar, and the next day wag his tail, remembering the food the beggar had bestowed.
>
> ([10.00], 304)

Well, why not? Does this not reflect the manner in which the currently prevailing techology seems to limit the powers of one's imagination? Certainly, Lewes's objection would pose no formidable obstacle to today's science of robotics. Moreover, from his own point of view, Lewes seems to have succumbed to a vitalist conception of mental states. What could be easier than to expose Lewes's regression by decerebrating a dog and then watching its behaviour after being repeatedly fed (as Goltz had in fact done). No doubt tail-wagging will turn out to have as mechanical (sentient!) an explanation as salivating. And yet, Lewes would seem to have placed his finger on a troubling problem: one which is impervious to conditioning experiments.

In place of Lewes's question we might ask: could an automaton dog

restrain itself from wagging its tail? Or better still, deliberately wag its tail in order to elicit food when it couldn't care less about seeing the beggar once again, or when it wasn't even hungry? For that matter, how can we be certain that the movements of a decerebrated animal are identical to those of an intact animal without observing its mind: perhaps reflexes step in when the mind ceases to control?

The real problem here is that, while Lewes and Huxley had succeeded in drawing an important distinction between mechanical and animal automata, this does not suffice to silence Descartes' attack on the continuum picture. One would hardly want to argue that the behaviour of a frog (the 'Job of physiology')—with or without its cerebrum—mirrors that of a human being when, for example, he has burnt himself. And while designating consciousness an emergent property may overturn the Cartesian picture of mental states and processes, it does nothing to reduce the Cartesian gulf between voluntary and involuntary behaviour. One can simply argue that voluntary actions are determined by preconscious mental causes.

The only way that the argument that 'There is no real and essential distinction between voluntary and involuntary actions, they all spring from Sensibility, they are all determined by feeling' could remove the Cartesian assumption that man, unlike any of the lower life forms, is endowed with a soul which determines 'those movements which we call "voluntary"', was by abandoning *mental causes* as conceived by Descartes altogether. Thus Huxley argued that:

> volition…is an emotion *indicative* of physical changes, not a *cause* of such changes. [T]he feeling we call volition is not the cause of a voluntary act, but the symbol of that state of the brain which is the immediate cause of that act.
>
> ([10.51])

But in order to sustain the voluntary/involuntary distinction, it was necessary to superimpose on this the premiss that the former are associated with a distinctive state of consciousness.

In *Hume* Huxley insists that 'volition is the impression which arises when the idea of a bodily or mental action is accompanied by the desire that the action should be accomplished' ([10.51], 184). Hence, the difference between voluntary and involuntary movements is phenomenological, not causal: the former are simply those actions accompanied by a special mental state (which is itself determined by past events). But then, this only serves to revive Descartes' attack on the continuum picture; for animals must also be capable of experiencing these attendant desires ('purposes'), and Huxley remained enough of a Cartesian to embrace the impossibility of knowing whether or not this

was the case (see [10.51]). This meant that there was only one direction in which a mechanism committed to continuity could proceed: dispense entirely with any causal distinction between 'voluntary' and 'involuntary' movements, and define the *apparent* difference between them in terms of experience.

Thus it was that the birth of psychology, like that of modern India, was marked by a bloody clash between two rival factions: in effect, those who wanted to confront Descartes' problem and those who wanted to deny it—James versus Loeb. This may seem an oversimplification of the conflict over whether this new science should be governed by physiology or philosophy, especially as far as the fathers of behaviourism are concerned. But the fact is that, one way or another, the prospects of the mechanist thesis depended at this point on the abolition of volitions. And this was precisely the move which Jacques Loeb pursued.

Frustrated with philosophy, Loeb had turned first to neurophysiology, then biology, in his quest to solve the 'problem of will'. Studying under Goltz, he became convinced that consciousness is irrelevant to behaviour, and could be eliminated from an exclusively associationist explanation of the purposiveness of automatic actions. 'What the metaphysician calls consciousness are phenomena determined by the mechanisms of associative memory' ([10.69], 214). He found the tool for implementing this programme in the work of Julius Sachs, who had employed the notion of *tropism*—the explanation of the 'turning' of a plant in terms of its physico-chemical needs in direct response to external stimuli—as a means of extending the reductionist outlook of the mechanistic quadrumvirate to botany. Seeing in tropisms a biological parallel to automatic movements, Loeb undertook to advance mechanism by employing Sachs' approach as a starting-point for the psychology of animal behaviour (Ibid., 1ff, 77).

The aim of Loeb's subsequent research on animal heliotropism was to exhibit various organisms as 'photochemical machines enslaved to the light'. To accomplish this, he demonstrated that when the caterpillars of *Porthesia chrysorrhoea* are exposed to light coming from the opposite direction to a supply of food, they invariably move towards the former, and perish as a result. Such experiments undermined the vitalist premiss that all creatures are governed by an unanalysable instinct for self-preservation: 'In this instance the light is the "will" of the animal which determines the direction of its movement, just as it is gravity in the case of a falling stone or the movement of a planet' ([10.70], 40–1).

Since it was in principle possible to explain 'on a purely physico-chemical basis' a group of 'animal reactions…which the metaphysician would classify under the term of animal "will"' (Ibid., 35), the answer to nothing less than the 'riddle of life' must lie in the fact that 'We eat, drink,

and reproduce not because mankind has reached an agreement that this is desirable, but because, machine-like, we are compelled to do so' (Ibid., 33). But surely, one wants to argue, Loeb's experiments had nothing to do with the 'problem of will'; in his own words, 'Heliotropic animals are…in reality photometric machines' (Ibid., 41). The fact that the caterpillars expired for want of food was no more a demonstration of (perverse!) purposive behaviour than the converse result would have supported vitalism. To suppose that their motor responses could exhibit the complexity of human purposive behaviour is once again to assume *ab initio* that *intentions* and *volitions* are simply part of a causal chain, from which the ability to choose, decide, select and deliberate are excluded a priori. But that was exactly what Loeb intended! This was not to be an isolated attack on the notion of *will:* all of the 'mentalist' concepts were to be removed from the eliminativist analysis of purposive—equals self-regulatin—behaviour.

That is not to say that the distinction between voluntary and involuntary movements would also have to be abandoned: only that it would have to be redefined accordingly. Loeb could only hint at the direction in which he thought this should proceed: it would indeed be in terms of 'associated memories', but Loeb was careful to explain that what he meant by the term was the (experimentally observable) 'mechanism by which a stimulus brings about not only the effects which its nature and the specific structure of the irritable organ call for, but by which it brings about also the effects of other stimuli which formerly acted upon the organism almost or quite simultaneously with the stimulus in question' [10.68], 72). In other words, a conditioned response.

Thus, Loeb, unlike Huxley, was able to salvage the continuum picture precisely because he eschewed the principle of sentient continuity. All that matters is that 'If an animal can be trained, if it can learn, it possesses associative memory' (Ibid., 72). This tied in with the Darwinian shift which occurred in late nineteenth-century mechanism.[17] In the conclusion to *Origin of Species,* Darwin had proclaimed that 'Psychology will be based on a new foundation, that of the necessary acquirement of each mental power and capacity by gradation' ([10], 488). And in *Descent of Man* he declared that 'the difference in mind between man and the higher animals, great as it is, certainly is one of degree and not of kind' [10.6]. Loeb was simply removing the 'mentalist' obstacles to this version of the continuum picture.

Mechanists quickly embraced this explanation of continuity (although there was considerable disagreement over whether this implied a single continuum, such as Spencer favoured,[18] or the picture of branching continuity championed by Darwin). What is perhaps most interesting, when looking at the development of mechanist thought at the beginning

of this century, is how quickly and thoroughly Loeb's outlook came to dominate American psychology. That is not to say it went unchallenged. Perhaps the most famous opposition came from Jennings in *The Behavior of the Lower Organisms* ([10.9]). But ironically, even though Jennings may be said to have won the biological battle, this only resulted in the further entrenchment of the mechanist as opposed to the psychic continuum which Jennings advocated (see [10.74]).

Jennings demonstrated, on the basis of Thorndike's trial-and-error experiments on the 'stamping in' of behaviour into cats, how it is possible to overcome tropic through conditioned responses. Hence purposive behaviour should be seen as an ongoing process in which an organism's physico-chemical needs interact with and are shaped by its environment.[19] But whatever damage this might have inflicted on the science of animal tropism, Jennings' opposition only served to promote even further Loeb's definition of purposive behaviour as a species of neurological adaptation and control, and the mechanist expectation that:

> the more complex activities of the body, which are made up by a grouping together of the elementary locomotor activities, and which enter into the states referred to in psychological phraseology as 'playfulness', 'fear', 'anger', and so forth, will soon be demonstrated as reflex activities of the subcortical parts of the brain.
>
> ([10.75], 4)

This was not intended to be read as a logical behaviourist thesis. Loeb and Pavlov were not urging that propositions about purposive or volitional behaviour can be reduced to or translated into propositions about molar or molecular behaviour. Rather, they were arguing that the former type of constructions are literally *meaningless* (although poetically resonant), while the latter capture the only sense in which the causes of behaviour can be intelligibly explained and thence controlled. The model for this argument was constituted by the mechanist resolution of the animal heat and reflex theory debates. Propositions about the homeostatic mechanisms sustaining thermal equilibrium, or about the sensori-motor system, did not supply the meaning of propositions citing vital forces, but rather, demonstrated the vacuity of the latter.

Pavlov made clear at the start of *Conditioned Reflexes* how his endeavour to 'lay a solid foundation for a future true science of psychology' (Ibid., 4) was the end-result of nineteenth-century mechanist thought: 'such a course is more likely to lead to the advancement of this branch of natural science' if it embraces the conception that:

> Reflexes are the elemental units in the mechanism of perpetual equilibration. Physiologists have studied and are studying at the present time these numerous machine-like, inevitable reactions of the organism—reflexes existing from the very birth of the animal, and due therefore to the inherent organization of the nervous system.
>
> (Ibid., 8)

In other words, so-called 'purposive' behaviour should be understood as the physico-chemical balance that an organism maintains by means of a complex system of 'Reflexes [which,] like the driving-belts of machines of human design, may be of two kinds—positive and negative, excitatory and inhibitory' (Ibid., 8).

In Pavlov's eyes, the key to this breakthrough lay in the advance of physiology from the study of bodily reflexes into the operations of the cerebral cortex. Pavlov saw himself as advancing Loeb's work by explaining animal behaviour in terms of what Charles Richet had called 'psychic reflexes' (Ibid., 5). He undertook to extend 'recent physiology['s]…tendency to regard the highest activities of the hemispheres as an association of the new excitations at any given time with traces left by old ones (associative memory, training, education by experience)' (Ibid.).

Significantly, Pavlov endorsed the 'new objective terminology to describe animal reactions' introduced by Beer, Bethe, and Üxküll, on the grounds that not only is there no justification for ascribing psychic processes to animals: there is simply no need. Hence the term 'purpose' is conspicuously missing from his writings. Indeed, early behaviourist thought was largely governed by this unwritten injunction to ignore and wherever possible redescribe the role of goals and intentions in human and animal behaviour. For the new psychology was to be an engineering science, unconcerned with any of the spurious issues bequeathed by the mind/body problem.

Nevertheless, their commitment to the continuum picture entailed that they could not avoid philosophical involvement, however acerbic their comments on the sterility of a priori reasoning. For the only way a mechanist continuum of purposive behaviour could be instituted was via an implicit analysis of the family of psychological concepts involved, such that the difference between *voluntary* and *involuntary* behaviour could be treated as one of causal complexity rather than kind. Thus, we find the leading behaviourists forced to deal with these philosophical problems which, so they repeatedly claimed, did not concern them in the least.

Watson exemplifies the pattern. In 'Psychology as the Behaviorist Sees It' [10.82] he makes it clear that his sole interest is in the issue of control.

This is still the primary focus in *Behavior* [10.83], but subsidiary concerns about the nature of thinking are beginning to creep in. By the time we get to *Behaviorism* [10.85] the book has become a fullscale defence of a 'behaviourist' philosophy of mind (the exact same progression can be traced in both Hull and Skinner's writings).

It may seem that all this was overturned by the transition to cybernetics, but as Volker Henn points out, the history of cybernetics really begins with Maxwell and Bernard [10.64], 174ff; cf. [10.18] 8if). The publication of 'Behavior, Purpose, and Teleology' [10.77] rnarks the consummation rather than reorientation of a prolonged conceptual evolution: viz., of the notion of machine *qua* homeostatic system that employs negative feedback to regulate its operations. (This is already clearly implicit in the passage from *Conditioned Reflexes* [10.75], quoted above.)

According to cybernetics, purposive behaviour is that which is 'controlled by negative feedback' in the 'attainment of a goal' (see [10.77]). We must be careful here, first, that we do not suppose that this thesis instituted a sharp break from behaviourism,[20] and second, that we do not impute the naive materialist outlook which guided the founders of behaviourism to all of their followers.[21] Nor should we suppose that the central theme of 'Behavior, Purpose, and Teleology'—viz., the relationship of teleological to causal explanation—had never before been broached. In fact, this problem had been a focus of mechanist concern for over three decades. What was primarily unique about 'Behaviour, Purpose, and Teleology' was rather the manner in which the authors sought to render teleological explanation scientifically respectable by rendering the feedback mechanisms in 'purposive' systems subject to the laws of causality. But far from just rewriting the logical form of teleological explanation (in order to bring out what they saw as its fundamental contrast with the antecedent—consequent form of causal laws), there are several points which stand out in the cybernetic analysis of 'purpose' or 'goal'.

To begin with, there are the central claims that 'purposive' behaviour be defined in terms of the goal-directed movements of a system interacting with its environment, where the goal itself is said to be a part of the environment with which the system interacts. The system is thus controlled by internal and external factors, and the existence of a goal is a necessary condition for the attribution of purposive behaviour. But 'goals' on the cybernetic model are simply the 'final condition' towards which a system is directed.

This represents a radical change in the meaning of 'purposive' or 'goal-directed behaviou'. In purposive behaviour, the relevant goal can be far removed, or even non-existent, without undermining the purposiveness of that behaviour. Indeed, it even makes sense to speak

of purposive behaviour occurring 'for its own sake' (as, e.g., in the case of singing (see [10.79], [10.80])). Moreover, the internal relations which bind the concept of purpose to those of consciousness, cognition, belief and volition, are rendered external. Hence the upshot of Rosenblueth, Wiener and Bigelow's argument is that there is no logical obstacle to describing cybernetic systems as 'purposive', even though they can exercise no choice, cannot be said to be trying to attain their goal, or even aware that such is their goal (as, e.g., in the case of guided missiles).

There is, of course, nothing to stop the mechanist from introducing a technical (cybernetic) notion of 'purpose' or 'goal', by which will be understood the state of equilibrium that the feedback mechanisms of a homeostatic system are designed or have evolved to maintain. But, as with the case of eliminative materialist theories, if the logico-grammatical distinction between 'purposive' and 'caused behaviour' is undermined, the result is not a new understanding of but rather, the abandonment of 'voluntary behaviour' and the creation of yet another misleading homonym.

Perhaps the most important aspect of cybernetics to bear in mind when assessing its significance for psychology is its continuity with behaviourism. Rosenblueth and Wiener insisted that:

> if the term purpose is to have any significance in science, it must be recognizable from the nature of the act, not from the study of or from any speculation on the structure and nature of the acting object…[Hence] if the notion of purpose is applicable to living organisms, it is also applicable to non-living entities when they show the same observable traits of behavior.
>
> ([10.76], 235)

As a corollary to this, they articulated the standard behaviourist thesis that multiple observations are needed to verify the existence of purposive behaviour (Ibid., 236). The judgement that an agent is is said to be an *inductive hypothesis* which, as such, must be supported by evidence. Most importantly, the theory remained committed to the continuum picture of purposive behaviour, now said to be governed by the 'orders of prediction' displayed by a system.

In typical Cartesian fashion, Rosenblueth, Wiener and Bigelow argued that:

> It is possible that one of the features of the discontinuity of behavior observable when comparing humans with other high mammals may lie in that the other mammals are limited to

> predictive behavior of low order, whereas man may be capable potentially of quite high orders of prediction.
>
> ([10.77], 223)

Reflex acts and tropisms can indeed be seen to be purposive (albeit of a lower order), complex actions are treated as nested hierarchies of bodily movements, and consciousness cannot be a necessary condition for purposive behaviour. For the theory does not distinguish between mechanical and biological systems; hence consciousness must be *emergent* and *epiphenomenal* (Ibid., 235; see [10.78]).

There are a number of important objections that have been raised against the cybernetic analysis of 'purposive behaviour' by AI scientists as well as philosophers (see [10.55]). From the standpoint of the former, the root of these problems lies, not in its mechanist orientation but rather, in the absence of 'a mechanistic analogy of specifically psychological processes, a cybernetic parallel of the mind/body distinction' ([10.57], 107). This lacuna is to be filled by the cognitivist distinction between embodied schemata and their neurophysiological components. These 'internal representations' are models of reality which 'mediate between stimulus and response in determining the behavior of the organism as a whole' ([10.56], 58). An organism uses these 'encoded descriptions' of its environment to guide its actions, and it is this which accounts for the purposiveness of its behaviour: not the misguided cybernetic supposition that there must be a goal which is a part of the environment with which a system interacts.

Assuming a fundamental analogy between computer programs and these 'internal representations', the crux of the post-computational version of the mechanist thesis lies in the premiss that, 'Insofar as a machine's performance is guided by its internal, perhaps idiosyncratic model of the environment, the overall performance is describable in intensional terms' ([10.57], 128).[22] The AI scientist endeavours to provide a mechanist account of purposive behaviour by postulating a species of 'action plans', neurally embodied, that are 'closely analogous to the sets of instructions comprising procedural routines within a computer program'. That is, internal representations both of 'the goal or putative end-state of an intention' and a possible plan of action for bringing about that state ([10.], 134; cf. [10.]).

Although this argument is committed to the (remote) possibility of discovering the neurophysiological mechanisms of these internal models, and thus of the discovery of causally sufficient conditions for purposive behaviour, all of the emphasis is on the manner in which these models guide an agent's behaviour (see [10.57]). While post-computational mechanists are committed, therefore, to the logical possibility of reducibility, they need not regard this as anything more

than a distant prospect. Hence, the much-celebrated shift from bottom-up to top-down approaches, i.e., to the computer simulation of the internal representations that guide purposive behaviour. For 'We can only postulate such models on behavioral grounds, and hypothesize that they correspond to actual neurophysiological mechanisms' ([10.56], 60).

On this picture, the 'explanatory power of a machine model of behavior depends on the extent to which the details of the underlying information-processing are functionally equivalent to the psychological processes actually underlying behavior' ([10.57], 144). Once the mechanics of human and animal purposive behaviour have been discovered, it will be seen that philosophical objections to the mechanist analysis of the 'continuum of purposive behaviour' are vacuous. Not because intentional and volitional concepts are eliminable, but because there is room for both purposive and causal categories in the explanation of human behaviour. The problem is, however, that this very premiss is denied by reductionism.

For all the technical sophistication of AI, it is interesting to see how little it has moved beyond the terms of Descartes' original argument. Indeed, so much so that the mentalist overtones of cognitivist theories have already sparked off strong eliminativist counter-movements in connectionism and neuropsychology. But the very fact that, for three centuries now, psychology has been dominated by these ceaseless 'paradigm-revolutions', with neither side able to refute Descartes' attack on the continuum picture, suggests that it is the framework established by Descartes' argument which needs to be addressed, not its results. That is, that the resolution of the problem created by mind/body dualism lies in the province of conceptual clarification *as opposed* to empirical theories: philosophy as opposed to psychology. And philosophy's chief concern here is with the persisting influence of the continuum picture: with the crucial premiss that all actions, animal and human, are complex sequences of movements brought about by hidden causes, the nature of which the science of psychology must discover.

V THEORY OF MIND

The latest effort to deal with the problems raised by Cartesianism involves a subtle attempt to retain the Cartesian picture of cognition while avoiding the eliminativism and reductionism which, as we saw in the preceding sections, has so dominated the evolution of psychology. Consider the case of a child suddenly becoming aware of its mother's feelings and interacting with her accordingly, or a child beginning to use

gestures or symbols to signal its intention. Cognitivism has a ready explanation for this type of phenomenon: the child's mind was busy all the while observing and recording regularities. What *looks* like a sudden moment of insight or development is really the end-result of preconscious inferences the child has drawn in which he has mapped causes onto effects. (E.g., 'Whenever S has this look on its face x invariably follows', or,'If I do x then y will happe', or,'If S believes x then S will ϕ'.) The argument is not committed to the premiss that beliefs, desires or intentions cause actions; only to the thesis that the child treats beliefs, desires or intentions as the causes of actions, which as such purportedly amounts to the claim that the child has formulated a theory of mind.

We are not supposed to worry overly about the use of *theory* here. Nothing terribly scientistic is intended (although one might feel otherwise when one reads the five points comprising the theory of mind which the child is supposed to have acquired: viz., (i) the mind is private; (2) mind is distinct from body; (3) the mind represents reality; (4) minds are possessed by others; and (5) thoughts are different from things (see [10.89]; [10.86] Wellman 1990)). But really, the use of the term is only meant to draw attention to the fact that in order for a child to be able to predict another agent's actions on the basis of his beliefs, the child must already possess such concepts as *self* and *person* or *desire* and *intention*. And, of course, the child must possess the concept of causation. So why, then, is the theory of mind thesis so drawn to the use of 'theory' to describe its thesis?

The answer is that the argument treats the ability to predict an agent's actions on the basis of his beliefs as a sub-category of the ability to predict events in general. That is, to predict S's actions on the basis of S's intentions, desires or beliefs is just a special case of predicting that x will cause y. The actual *theory* which the child must construct is simply the framework filling out the conditions of this 'special case'. The emphasis here is on treating human behaviour as a different kind of phenomenon from physical. Intentions, desires and beliefs are postulated because they prove to be such useful constructs for predicting human—and only human—behaviour (where this, too, is something the child must learn; i.e., at first he blurs the lines between human actions and physical events, or between human and animal behaviour, but he soon learns the ineffectiveness of using mental constructs to predict the latter types of phenomena). But prediction is prediction, whether it be in regards to human actions or physical events, i.e., regularities must be observed, causal connections perceived.[23]

This is precisely what the argument is driving at when it talks of how 'a theory provides a causal-explanatory framework to account for, make understandable, and make predictable phenomena in its domain' (Ibid., 7). We can see how this is supposed to work by looking

more closely at the actual type of theory which the child is supposed to create.[24] The process of constructing such a theory is said to take place on two planes: the child is making discoveries about itself at the same time that it is observing regularities in the actions of other human beings. So first, the child has to discover that it is a *self*, and then, that another is an *other*. To do this the child has to discover that intentional actions are not reflexes, i.e., that there are two basic kinds of movements in the realm of human behaviour. We get a residue of the orthodox Cartesian account of 'privileged access' in the emphasis on a child's learning that it can manipulate objects—or its caretakers—and extrapolating from this the concepts of *self* and *object;* or learning what its own beliefs, desires or intentions are, and then, what beliefs, desires or intentions are. While all this is going on, the child is busy observing the difference between the way its caretakers and other humans move about and the way inanimate objects are moved. In this sense, the discovery of the distinction between voluntary and involuntary behaviour is seen as a complex synthesis of self, social and object perception.

We should, perhaps, be more careful about using the term 'discover'; for according to the theory of mind, it is not so much that the child observes that voluntary movements are different from involuntary as that the child discovers that it is more useful, when interacting with humans, to make this distinction. That is, it is not so much that the child discovers what intentional behaviour *is* as that it discovers the value of postulating beliefs, desires or intentions for predicting human behaviour. In so doing, the child is said to realize that other agents have minds. For since beliefs, desires and intentions are not visible, the child treats them as hidden causes of behaviour. That is, the child establishes for itself that beliefs, desires and intentions are mental entities. It establishes that the difference between two seemingly identical actions done with different beliefs, desires or intentions must reside in the concealed mental causes.

As we saw in the preceding sections, mechanism soon discovered that the distinction between voluntary and involuntary movement must be more complex than this brief sketch suggests. The child must also discover the importance of postulating purposes, and goals, and decisions, and choice, and effort. The child must discover that voluntary actions, unlike reflexes or accidents, are somehow willed and not externally caused. The child must determine that, like ordinary causes, an agent can have a belief, a desire or an intention in advance of acting on it, but unlike ordinary causes, an agent can form a belief, a desire or an intention without necessarily acting on it; i.e., the child must discover that beliefs, desires and intentions can be treated as causing but not as forcing actions. And unlike the case of ordinary

causes, the child must learn that only he can know what his beliefs, desires or intentions are.

The entrance of language—or rather, the entry into language—is thought to add still more complexity into the child's construction of a theory of mind. To begin with, the child must learn how to map his beliefs, desires and intentions onto words. He must learn the effect of using avowals of belief, desire or intention on others. As the child gets more cognitively sophisticated, he learns how to use expressions of belief, desire or intention to conceal his real feelings or intentions. Verbal habits or routines can then begin to take over, so that language becomes, not just a vehicle for deception, but an actual barrier to genuine communication. The child also learns how to read things into other agents' avowals. It must learn that beliefs, desires and intentions can be the grounds for judging the morality of an action: an element which forces the child to sharpen his 'fundamental, ontological distinction… between internal mental phenomena on the one hand and external physical and behavioral phenomena on the other' ([10.89], 13).

The more one reads about this 'fundamental ontological distinction', the more apparent it becomes that the theory of mind thesis rests on a subtle tension. The very premiss that the ability to recognize another agent's beliefs, desires or intentions—to grasp that other agents have beliefs, desires and intentions—amounts to the construction of a *causal-explanatory framework,* turns on the presupposition that the ability to predict an agent's actions on the basis of his beliefs, desires or intentions is a sub-category of prediction in general. But in effect, all of the above contrasts represent an attempt to divorce intention from prediction. That is, the 'theory' which the child must construct is one which carefully marks the various distinctions between predicting an agent's behaviour on the basis of his beliefs, desires or intentions, and predicting causal events.

Thus, the child must learn that when an agent says 'I'm going to ϕ ' he is not making a prediction which is akin to 'It's going to rain'. If an agent says 'I'm going to ϕ' in all sincerity, and then fails to do so because something prevented him, that doesn't mean his intention was *wrong* (as is the case if he predicts it is going to rain and we get sunny skies instead). More fundamentally, a child does not learn what his beliefs, desires or intentions are inductively. He neither infers from his own behaviour that he had the intention to ϕ, nor does he observe that whenever he forms the intention to ϕ he invariably ϕs (in the way that he observes how the same effects result from the same cause). He does not discover that, should he want to ϕ, all he has to do is form the intention and the state of his ϕing will subsequently occur. The child learns that when he says 'I'm going to ϕ' he is committing himself to a course of

action, i.e., that the act of uttering these words arouses certain expectations in his listener as to how he will behave. He learns that, should an agent fail to ϕ after announcing his intention to do so, this may indicate the presence of countervailing factors, or it might signify that the agent changed his mind, but whatever the reason, it licenses the demand for some explanation as to why the agent failed to ϕ (without entailing that there must be an answer). That is not to say that one cannot be wrong about one's beliefs, desires or intentions. But the child learns that to be wrong about about one's beliefs, desires or intentions is a very particular language game. It is not at all like being wrong about the weather. It suggests hidden motives, or that one is driven by forces or factors of which one is unconscious, or that one suddenly has a new insight into one's own behaviour or needs.

The theory of mind trades on the fact that there is often (but not necessarily) a temporal relation between intending to ϕ and ϕing. If an agent decides at t to ϕ at t_1 and then does so there is clearly a temporal relation between his initial decision and subsequent behaviour. But that neither entails that there is a causal relation between two events—a mental and a physical—nor that we construe an agent's behaviour in these terms. For we must be careful to distinguish between the temporal relation between the time (if there is one) at which an agent formed the intention and the time at which he acted, and the rule of grammar which stipulates that this action represents the satisfaction of this intention. It is the rule of grammar 'The intention to ϕ is satisfied by the act of ϕing' which governs our accounts of what counts as acting in accord with the intention. But on the causal picture embraced by the theory of mind, we would be forced to accept that whatever S does at t_1 must be deemed the consequence of his intention to ϕ. If S ψs then his intention to ϕ was satisfied by his act of ψing. Hence the child is conceived as learning, not only that it is highly likely that an agent will ϕ if he intends to ϕ, but that it is highly likely that ϕing represents the satisfaction of the intention to ϕ! (see [10.55]).

Suppose we view a child's burgeoning social awareness, however, not as a species of causal perception, but something entirely—categorially—different, i.e., a skill which demands a totally different grammar—for example, the grammar of agency and intentionality as opposed to causality—for its proper description. All of the above statements outlining the 'contrasts' between predicting an agent's actions on the basis of his beliefs, desires, or intentions and predicting the effects of a given cause can be seen as the rules which formulate this grammar. For example, the above statement 'The child learns that only he can know what his intentions are' exemplifies what Wittgenstein calls a *grammatical proposition:* '"Only you can know if you had that intention." One might tell someone this when one was explaining the meaning of

the word "intention" to him. For then it means: *that* is how we use it. (And here "know" means that the expression of uncertainty is senseless.)' ([10.91], section 247) Treat this as an *empirical proposition*, however, and you find yourself mired in sceptical problems: not just with regard to third-person knowledge (viz., you can never be certain that you know what another person intends), but even with respect to first-person knowledge (unless one decides to hold fast—despite all the evidence gathered in [10.87]—to the doctrine of privileged access to one's own mental states).

Remove the Cartesian starting point that predicting an agent's actions is a sub-category of prediction in general, and it is no longer tempting to suppose that a child who knows what another agent believes, wants or intends has inferred the existence of an antecedent mental cause guiding that agent's behaviour. That does not vitiate the importance of the larger point that the theory of mind is making, which is that to say that a child grasps another agent's beliefs, desires or intentions is to say that he grasps or even shares what they see or feel, and can thus anticipate what they will do if given the opportunity. But this, too, is a *grammatical*, not an empirical proposition; one might tell someone this when explaining the meaning of the expression 'to grasp another agent's beliefs, desires or intentions'. Likewise, the theory of mind's basic claim that to possess the concept of false belief a child must possess the concepts of self, person, desire and intention is a grammatical, not an empirical proposition or hypothesis. Whether it is the *right* grammatical proposition is another matter: something which can only be resolved by a philosophical, not a psychological investigation.

It is important to note that, to know what another agent believes, wants or intends does not entail that one must know what beliefs, desires, or intentions are; for the criteria for saying 'S knows what R believes' are very different from the criteria for saying that 'S knows what a "belief" is'. As the quotation marks indicate, the latter demands the ability to speak a language. When a child learns how to *describe* the beliefs, desires or intentions which guide an agent's actions, what he learns are the grounds for attributing such a belief, desire or intention when explaining the nature of someone's actions. He learns how appropriate behaviour *justifies* but does not entail the attribution of beliefs, desires or intentions. Thus, the child learns when it is correct to cite those beliefs, desires, or intentions as one's reasons for ϕing (e.g. when justifying one's actions or explaining someone else's). And he learns that the fact that one can appear to be acting intentionally without having any definite intention in mind, or conversely, conceal one's beliefs, desires, or intentions, merely attests to the fact that such criterial evidence is defeasible: not that in assigning beliefs, desires or intentions

one is framing hypotheses or forming inductive generalizations about the probable causes of S's ϕing.

As far as the voluntary/involuntary distinction is concerned, we might say that what the child learns is how, by describing an agent's beliefs, desires or intentions, the possibility that his behaviour was caused or accidental is excluded. The attribution of beliefs, desires and intentions 'explains action', not in the causal sense that it identifies the factors that *brought about* someone's behaviour, but in the *constitutive* sense that it establishes the *meaning* or the *significance* of an action. If beliefs, desires or intentions were hidden causes, then a statement like 'The intention to ϕ is satisfied by the act of ϕing' would be '*hypothetical* in the sense that further experience can confirm or disprove the causal nexus' ([10.90], 120). And if that were the case, then it would indeed make sense to speak, without qualification, of having beliefs, desires or intentions without knowing what they were in the same way that one can be ignorant of the causes of *x,* or of inferring, learning, suspecting or being wrong about what one believes, wants, or intends. But '"I know what I want, wish, believe, feel,…" (and so on through all the psychological verbs) is either philosophers' nonsense, or any rate *not* a judgement *a priori*' ([10.91], 221). That is, apart from such cases as when an agent is undecided (and in that sense uncertain) as to which course of action to pursue, or when prodding someone to question or confront their real desires or beliefs, it is inappropriate to ask someone whether he is certain that he knows what he believes, wants, or intends. For in ordinary circumstances, how else could one respond to such a question other than: my intention to ϕ is the intention that *I* should really ϕ? If a further explanation of this assurance is wanted I would go on to say 'and by "I" I mean myself, and by "ϕ" I mean doing this…': 'But these are just grammatical explanations, explanations which *create* language. It is *in language* that it's all done' ([10.], 143).

Wittgenstein's point here is that, in ordinary circumstances, the only response one can make to persistent doubt is to explain or reiterate the rules of grammar which govern the use of *belief, desire* or *intention*. He is not suggesting that an understanding of other agents' beliefs, desires or intentions can only be attributed to creatures that possess the ability to speak a language. Nor is he seeking to inculcate scepticism; quite the contrary, he is seeking to undermine epistemological scepticism by demonstrating that the issue that concerns us here is not *whether we can ever be certain that S can ϕ* (where ϕ might be *think,* or *feel,* or *intend,* or *understand,* or *mean,* etc.), but *how we describe what S is doing* or *what S understands*. In paradigmatic contexts this distinction is (typically) of no concern; it is in the borderline cases, and especially, in primitive contexts, where it becomes easy to confuse the question of whether S's behaviour satisfies the criteria for describing him as ϕing with the sceptical question

of whether we can ever be certain that S is really or merely appears to be doing so. This is the reason why Cartesianism has become such a dominant force in comparative primatology and developmental psychology, and why both behaviourism and cognitivism—i.e., the denial of higher mental processes or the assignment of these higher mental processes to the preconscious—have flourished in these domains. But far from lamenting the indecisiveness which seems to characterize these discussions, we might see this uncertainty as a crucial aspect of psychological concepts.

This last point demands clarification. One of the more glaring problems with the theory of mind is that the terms of the discussion seem so remote from the reality of an infant's behaviour. For example, we are asked to accept, not just that a baby observes regularities, but even, that a baby *makes observations*. The baby does not just suck whatever comes into its purview; it *discovers by trial and error* which things in its world are suckable; it *frames hypotheses* as to the *class of suckable objects* and then *performs experiments* to *test its hypotheses*. The child who is sharing or initiating joint attention is actually *constructing laws* of human behaviour. And indeed, the human infant, virtually from birth, is *predicting* events; what changes as it develops is not this innate scientistic drive, but the power of the constructs whereby it makes its predictions.

It is little wonder that this picture of prediction (of going beyond the information given) summons up a thesis like the theory of mind. For it seems to make little sense to speak of an agent as predicting something unless he possesses the requisite concepts involved. Thus, the theory of mind insists that, if we are dealing with predicting physical events, then at the very least the subject must possess the concepts of causation, object and object permanence; if we are talking about predicting social events, then the subject must possess the concepts of self, agent, intention and desire. But we lose sight here of what a rarefied concept the concept of concept is. A 2-year-old can do some very extraordinary things which, as Tomasello shows, bear fundamentally on what the theory of mind thesis is trying to explain (see [10.88]). For example, a 2-year-old can share and can even direct attention. But does a 2-year-old jointly attending to something possess the concept of *joint attention*? Does he even know or understand that other agents have thoughts or desires which may differ from his own? Does he possess the concepts of *self* and *person* and *intention*? And most important of all, are these sceptical questions?

Once again we are in danger of straying too far from what we are observing: of reading too much into a child's primitive interactive behaviour. To be sure, there are significant events in the child's development, cognitive feats which stand out as 'developmental

milestones'. But does a child's becoming aware of its mother's feelings and interacting with her accordingly satisfy the criteria for saying that it possesses the concept of person? Does 'passing' the Wimmer—Perner test satisfy the criteria for saying that it possesses the concept of false belief? How else, the Cartesian wants to say, could the child perform these acts unless he possessed these concepts, or at the very least, was capable of representing human behaviour in different terms from physical. Granted, it is always possible—irrevocably possible—that we are misrepresenting the child's representation. But the one thing that is certain, according to Cartesianism, is that the child's behaviour must be concept-driven.

It would take us too far outside the scope of this chapter to chart the origins and conceptual problems involved in the view of concepts as the 'repositories of featural analysis' on which this argument rests. What principally matters to us here is that this view of concepts goes hand-in-hand with the view that social awareness is grounded in a theory of mind. Indeed, in recent years concept-formation has itself come to be seen as a species of theory construction. But these problems disappear when we regard an agent's behaviour, not as *evidence* of the concept which he has formed, but as constituting a *criterion* for saying that he possesses the concept ϕ. That is, when we view the statement 'Doing x, y, z constitutes the criterion for saying that "S possesses the concept ϕ"', or more generally, 'Saying that S possesses the concept =Saying that S can do x, y, z' is a rule of grammar, not an empirical proposition. For this means that the statement 'S possesses the concept ϕ' does not describe or refer to a mental entity but rather, is used to attribute certain abilities to S.

For example, to say that S possesses the concept *number* is to say that S can do sums, can apply arithmetical operations, can explain what a number is, can correct his own or someone else's mistakes, etc. Doing all these things does not count as evidence that S possesses the (or a) concept of number; rather, it satisfies the criteria for saying 'S possesses the concept *number*'. Similarly, if a child hides the treat which his mother has given him in the hopes of getting another from his father, this is not evidence that he has acquired the concept of *pretence*—which, according to the theory of mind, entails a theoretical understanding of desire and intention, and possibly, of belief—but rather, a criterion for saying that the child is capable of pretence. Where the theory of mind has been so valuable is in drawing attention to the importance of the conceptual relations enshrined in the above statement. For this is not an empirical proposition: a description of the end-result of the step-by-step process whereby a child has built up a complex construct like 'pretence' (in the same way, for example., that one could describe the mechanics of a pattern recognition system). It is rather a grammatical proposition,

stipulating that it makes no sense to speak of a child as *pretending to* ϕ unless it also makes sense to describe the child as *intending to* ϕ, *wanting* x, etc. Thus, theorists of mind have been actively engaged in a twofold enterprise: that of mapping the conceptual relations entailed by the application of some psychological concept, and then studying a child's behaviour to ascertain whether it satisfies the necessary criteria or perhaps can be said to satisfy a still more primitive version of the concept in question.

To insist that a subject's behaviour fails to satisfy the criteria for applying some concept, for example, that directing its mother's attention to an object does not satisfy the criteria for saying of a 2-year-old child that it possesses the concept of *person*, does not entail that this behaviour can only be described in causal terms, i.e., that the child did not, after all, *direct its mother's attention*. Wittgenstein makes a point about the origins of causal knowledge which is highly pertinent here. There is, Wittgenstein observes, 'a reaction which can be called "reacting to the cause"' ([10.94]). Consider the case of a small child following a string to see who is pulling at it. If he finds him, how does he know that he, his pulling, is the cause of the string's moving? Does he establish this by a series of experiments? The answer is No: this is rather a primitive case of what is called 'seeing that x was the cause of y'. Only a strong Cartesian bias could induce one to construe this phenomenon as a manifestation of a form of induction. But in order to make sense of the notion of the child exhibiting in such behaviour his mind's 'pre-linguistic causal inferences', it would also have to make sense to speak of the child's exhibiting pre-linguistic manifestations of doubt: of making mistakes in his causal reasoning and taking steps to guard against error, of testing, comparing, and correcting previous judgements. But none of his behaviour satisfies the criteria for attributing these abilities: all he did was react to the cause.

The language game played with 'cause' exemplifies Wittgenstein's point in *Last Writings* about how:

> A sharper concept would not be the same concept. That is: the sharper concept wouldn't have the *value* for us that the blurred one does. Precisely because we would not understand people who act with total certainty when we are in doubt and uncertain.
>
> ([10.93], Section 267)

For example, the very notion of *reacting to a cause* is blurred; the child *saw* that x caused y, whereas the caterpillars in Loeb's experiments merely *reacted* to the light. Just as the cases where it is appropriate to speak of a *conditioned response* merge into circumstances where it is appropriate to speak of *seeing that x caused y*, so, too, the cases where it is appropriate to

speak of *seeing that x caused y* merge into circumstances where it is appropriate to speak of *knowing that x will cause y*. We can indeed speak of a continuum here, therefore, but it is *grammatical,* not cognitive: a language game ranging from *reacting to a cause* to *counterfactual reasoning*. This grammatical continuum demands ever more complex behaviour to license the attribution of ever more complex abilities and skills. At the lowest end of this spectrum is that behaviour which satisfies the criteria for what is called 'reacting to a cause'. At this primitive level, S's behaviour satisfies the criteria for describing him as being aware of the cause of *y,* but his behaviour comes nowhere close to satisfying the criteria for saying that he possesses the concept of *cause*. As the child acquires linguistic abilities, we teach him how to use 'cause' and 'effect'. It is his growing understanding of causal relations, as reflected in his growing mastery of the family of causal terms that satisfies the criteria for describing him as possessing the concept of *cause,* i.e., as possessing the ability to infer and predict events, to doubt whether *y* was caused by *x* and to verify that *x* causes *y*. We continue to move up the grammatical continuum as the subject learns the importance of observation and experiment, culminating in the advanced abilities to engage in counterfactual reasoning or *Gedankenexperimente,* to construct theories and models, and theories of theory and model making.

The important point here is that, rather than following Descartes' lead and beginning with the paradigm of the scientist—of the scientist's mind—and reading this into all the lower forms of behaviour as we work our way backwards through a descending level of cognitive abilities, so that the mere reaction to a cause is construed as manifesting a 'pre-conscious causal inference', we proceed by clarifying the relation between primitive expressive behaviour and primitive uses of psychological concepts, and show how the roots of *causal inference* lie, not in 'mental processing' but rather, in these primitive uses:

> The origin and the primitive form of the language game is a reaction; only from this can more complicated forms develop. Language—I want to say—is a refinement, 'im Anfang war die Tat'…it is characteristic of our language that the foundation on which it grows consists in steady ways of living, regular ways of acting… We have an idea of which ways of living are primitive, and which could only have developed out of these … The simple form (and that is the prototype) of the cause-effect game is determining the cause, not doubting.
>
> ([10.94])

Similarly, the roots of *social understanding* lie in primitive reactions and interactions, e.g. in the fact that at 9 months old a child can be

conditioned to follow a caregiver's gaze and to share a caregiver's emotions; at 12 months the child begins to follow the caregiver's gaze spontaneously, and shortly after this, to initiate and direct joint attention; while at much the same time it begins to use imperative pointing, and soon after this, declarative pointing. But the fact that the infant is able to look where another agent wants, to attend to directed objects and situations or direct another where to look, or to use certain gestures and then conventionalized sounds to initiate exchanges, does not in itself constitute theoretical or pre-theoretical knowledge. The infant is learning how to participate in very particular kinds of social practices (giving and requesting objects, playing peek-a-boo, asking and answering simple questions). As the child's mastery of these practices advances, it makes increasing sense to describe the child as 'intending or trying to ϕ', as 'looking or hoping for x', as 'thinking or believing p', and so on.

In other words, what people say and do is what constitutes the justifying grounds for psychological ascriptions. Scepticism about other minds stems from misconstruing this logical relation as inductive evidence. It turns on Descartes' idea that what we see are 'colourless movements' from which we infer a hidden cause. But we do not see *mere behaviour,* we see, for example, pain behaviour, i.e., that behaviour which satisfies the criteria governing the application of 'pain'. The sense in which pain behaviour 'falls short of certainty' is solely that it does not *entail* that someone is in pain. But this has nothing to do with perceptual limitations.

Descartes capitalized on the fact that psychological concepts cannot be applied to lower lifeforms. Unfortunately, he misconstrued the nature of this 'cannot'. For these limits are imposed by logical grammar, not experience. Descartes was quite right to draw attention to the importance of the fact that animals do not utter avowals: but for reasons that have nothing to do with his animal automaton hypothesis. The application of psychological concepts is intimately bound up with the ability to speak a language: to describe one's state of mind, express one's desires and intentions, report on one's feelings (or conceal them). But that does not mean that animals are incapable of manifesting primitive expressive behaviour; for a dog's howling, like a baby's, may indeed be a criterion for saying that it is in pain.

The result of misconstruing the grammatical propositions or rules governing the use of psychological concept words as empirical propositions has been three centuries of conflict over whether intentions, desires, beliefs, etc. in some way cause the actions they are thought to accompany or precede, and whether these mental phenomena correspond to or are caused by neural events. The persisting assumption has been that we start off with these mental events and then try to

discover the cerebral mechanisms with which they are correlated or by which they are caused. But the lesson to be learnt from studying the mechanist/vitalist debates is that the real evolution of this psycho-physical parallel thesis was the exact opposite: it was by proceeding from the premiss that all involuntary movements are caused by external and internal stimuli, and the persisting desire to restore the continuum picture by reducing voluntary actions to the same terms, that the notion of 'mental cause' was created: the conception of intentions, desires, beliefs as mental events that bring about actions precisely because they initiate or are isomorphic with the cerebral drive train that provides the motor power. The goal of this chapter has been, not just to chart the development of these ideas, but more importantly, to reverse this way of thinking: to establish the unique and non-causal character of mental concepts in order to clarify why it is so misleading to assume that 'psychology treats of processes in the psychical sphere, as does physics in the physical' ([10.91], section 571). Thus, my intention here has been, not to praise Descartes' legacy, but to bury it: to relegate the mechanist/vitalist debates once and for all to the *history* of psychological ideas.

NOTES

1 It is highly significant that Russell should have written an introduction to Lange's *History of Materialism,* in which he states that: 'Ordinary scientific probability suggests…that the sphere of mechanistic explanation in regard to vital phenomena is likely to be indefinitely extended by the progress of biological knowledge' ([10.38], xvii–xviii).

2 Du Bois-Reymond followed up on his argument with an expanded account in 1880 of the 'seven world problems'. In addition to the matter force and brain thought problems he now included the origins of motion, life, sensation and language, the teleological design of nature and the problem of free will (see [10.23]).

3 Spencer's explanation of the 'continuous adjustment of internal relations to external relations' also reflects the influence of Liebig's views ([10.40]).

4 In *Animal Chemistry* he warned that:

> The higher phenomena of mental existence cannot, in the present state of science, be referred to their proximate, and still less to their ultimate, causes. We only know of them, that they exist; we ascribe them to an immaterial agency, and that, in so far as its manifestations are connected with matter, an agency, entirely distinct from the vital force *with which it has nothing in common*.
>
> ([10.25], 138)

5 As indeed do cognitivists, albeit for vastly different reasons. In their eyes Bernard's metaphor manifests the latent tendency to regard biological phenomena 'in terms of categories whose primary application is in the

domain of knowledge' [10.19]. It thus illustrates the inadequacy of physico-chemical concepts to explain such biological phenomena as embryological development; for as Bernard himself was to explain:

> In saying that life is the directive idea or the evolutive force of the living being, we express simply the idea of a unity in the succession of all the morphological and chemical changes accomplished by the germ from the beginning to the end of life. Our mind grasps this unity as a conception which is imposed upon it and explains it as a force; but the error consists in thinking that this metaphysical force is active in the manner of a physical force.
>
> [([10.37], 214)

But where the cognitivist sees the organism itself as the intended bearer of Bernard's *directive idée,* Bergson had earlier insisted that it is a 'principle of interpretation': in modern usage, a paradigm whereby a scientific community construes its data (Ibid., 148–9). As we shall see, this is a recurring theme in this whole debate. One suspects, however, that for a proper understanding of how Bernard himself viewed his *directive idée,* one should look at the psychistic theory of growth whose antecedents date back to Proutt and Bichat (see [10.27], 238–9, 250).

6 Even Turing's attempt to discover the algorithms determining the evolution of plant life betrays an underlying goal of laying classical vitalist themes to rest.

7 A young player upon the harpsichord or a dancer, is, at first very thoughtful and solicitous about every motion of his fingers, or every step he makes while the proficients or masters of these arts perform the very same motions, not only more dexterously, and with greater agility, but almost without any reflexion or attention to what they are about' ([10.47], 79).

8 Cf. Herbert Mayo's argument that:

> there are many voluntary actions, which leave no recollection the instant afterwards of an act of the will. I allude to those, which from frequent repetition have become habits. Philosophers are generally agreed, that such actions continue to be voluntary, even when the influence of the will is so faint as to wholly escape detection. We are therefore not authorized to conclude that instinctive actions are not voluntary merely because we are not conscious of willing their performance.
>
> ([10.47], 125)

9 According to Lotze:

> When, under the influence of the soul life an association has once been formed between a mere physical impression of a stimulus and a movement which is not united with that stimulus by the mere relation of structure and function, and when that association has been firmly established, this mechanism can continue the activity without requiring the actual assistance of intelligence.
>
> ([10.47], l64)

10 After describing in 'The Spinal Cord a Sensational and Volitional Centre' (1858) how he had replicated Pflüger's experiment, Lewes concluded:

> If the animal is such an organized machine that an external impression will produce the same action as would have been produced by sensation and volition, we have absolutely no ground for believing in the sensibility of animals at all, and we may as well at once accept the bold hypothesis of Descartes that they are mere automata. If the frog is so organized, that when he cannot defend himself in one way, the internal mechanisms will set going several other ways—if he can perform, unconsciously, all actions which he performs consciously, it is surely superfluous to assign any consciousness at all. His organism may be called a self-adjusting mechanism, in which consciousness finds no more room than in the mechanism of a watch.
>
> ([10.47], 168)

11 Thus Lewes explains:

> The Actions cannot belong to the mechanical order so long as they are the actions of a vital mechanism, and so long as we admit the broad distinction between organisms and anorganisms. Whether they have the special character of Consciousness or not, they have the general character of sentient actions, being those of a sentient mechanism. And this becomes the more evident when we consider the gradations of the phenomena. Many, if not all, of those actions which are classed under the involuntary were originally of the voluntary class—either in the individual or his ancestors; but having become permanently organized dispositions—the pathways of stimulation and reaction having been definitely established—they have lost that volitional element (of hesitation and choice) which implies regulation and control.
>
> ([10.53], 416–17).

12 Thus William Graham explained how:

> consciousness is only, as Professor Tyndall has termed it, an accidental 'bye-product'—something over and above the full and fair physical result, which by an accident, fortunate or otherwise, appeared to watch over and register the whole series of physical processes, though these would have bone on just as well in its absence.
>
> ([10.48], 122)

It is noteworthy in light of the interrelatedness of the various issues involved in the mechanist/vitalist debate that he concluded: 'In this case, thought or consciousness would not consume any of the stock of energy; the law of conservation of energy would not be threatened in its generality; and man would be a true automaton, with consciousness added as a spectator, but not as a director of the machinery' (Ibid., 123; cf. [10.51], 240 ff.).

13 The closest one comes to even a hint of awareness of this issue is George Paton's insistence that 'if these movements be not of a perceptive character then there is no meaning in language, and we must give a new definition to the term perception' ([10.47], 154).

14 The failure to grasp this point marred Haller's otherwise penetrating observation in *First Lines of Physiology:*

> that the nature of the mind is different from that of the body, appears from numberless observations; more especially from those abstract ideas and affections of the mind which have no correspondence with the organs of sense. For what is the colour of pride? or what the magnitude of envy or curiosity?
>
> ([10.49] 11, p. 45)

But, of course, it is the human being who feels pride, envy and curiosity, not his mind or brain.

15 The height of this absurdity was reached by T.L.W.Bischoff. Fearing recounts how, in his 'Einige Physiologisch-anatomische Beobachtungen aus einem Enthaupeteten' Bischoff states that:

> he was especially concerned with the question of the persistence of consciousness in the head segment [of recently executed criminals]. The experiments were performed during the first minute after decapitation. The results were wholly negative. The fingers of the experimenters were thrust towards the eyes of the decapitated head, the word 'pardon' was called into the ears, tincture of asafoetida was held to the nose, all with negative results. Stimulation of the end of the severed spine did not result in movement.
>
> ([10.47], 152)

16 In what reads as the vitalist anticipation of the objection from Watson cited at the beginning of Section i above, Lewes maintained:

> All inductions warrant the assertion that a bee has thrills propagated throughout its organism by the agency of its nerves; and that some of these thrills are of the kind called sensations—even discriminated sensations. Nevertheless we may reasonably doubt whether the bee has sentient states resembling otherwise than remotely the sensations, emotions, and thoughts which constitute human Consciousness, either in the general or the special sense of that term. The bee feels and reacts on feelings; but its feelings cannot closely resemble our own, because the conditions in the two cases are different. The bee may even be said to think (in so far as Thought means logical combination of feelings), for it appears to form Judgments in the sphere of the Logic of Feeling… although incapable of the Logic of Signs… We should therefore say the bee has Consentience, but not Consciousness—unless we accept Consciousness in its *general* signification as the equivalent of Sentience.
>
> ([10.53], 409; cf. 434).

17 Interestingly, Erasmus Darwin had argued at the end of the eighteenth century that animals are no less capable than man of reasoning (of concatenating sensory ideas according to the laws of association ([10.62], 15.3). Indeed, the fact that an organism like the fruit fly often mistakes the carrion flower for carrion is proof of its ability to sustain correct reasoning (Ibid., 16.11).

18 'In tracing up the increase we found ourselves passing *without break* from the phenomena of bodily life to the phenomena of mental life' ([10.40], section 13).

19 All of the attention here has been fixed on the notion of purposiveness, but it

bears noting in the sequel how the so-called ambiguity between 'behaviour as movement' and 'behaviour as action' was becoming an established fact. When Rosebleuth, Wiener, and Bigelow introduced cybernetics they could simply assume without qualification that 'By behavior is meant any change of an entity with respect to its surroundings… [A]ny modification of an object, detectable externally, may be denoted as behavior' ([10.77], 18). It should be noted, however, that this long-established usage of 'behaviour' was, in fact, originally regarded as metaphorical.

20 Rosenblueth, Wiener and Bigelow insisted that their goal was 'a uniform behavioristic analysis [which] is applicable to both machines and living organisms, regardless of the complexity of the behavior' ([10.77], 18, 24, 22). Cf. George:

> It must be emphasized very strongly that cybernetics as a scientific discipline is essentially consistent with behaviourism, and is indeed a direct offshoot from it. Behaviourists, in essence, are people who have always treated organisms as if they were machines.
>
> ([10.63], 32)

21 There is a tendency to rule that anyone straying from the orthodox materialist course is automatically excluded from the behaviourist fold; an obvious example is Tolman, but even a figure such as Hull, who expresses cybernetic sentiments in *Principles of Behavior* (see [10.65], 26–7) is often regarded as only a partial (i.e. neo-) behaviourist (and *de facto* 'father' of cybernetics). But what is one to make of a figure such as Lashley (see [10.67])?

22 It should be noted that this argument marks a shift in focus from the subject of machine intelligence to that of cognitive modelling. For the very fact that these internal representations can be mechanically simulated, thereby enabling us to describe cybernetic systems in purposive terms, might also 'provide a key to understanding the way in which the corresponding [human or animal] behavior is actually produced' ([10.57] 142).

23 Since perception can also be treated as a constructive, or an inferential process, this reference to *causal perception* does not need to be qualified.

24 Nativist arguments are ignored in what follows, but really they are just as much a concern of this discussion. For the emphasis here is not on *construction,* it is on *cognition:* on what the child must putatively know in order to display the various abilities recorded by developmentalists.

Glossary

GENERAL

ab initio—Latin, 'from the beginning'.

absolute—From the Latin *absolutus,* meaning 'the perfect' or 'completed'. The term further means independent, fixed and unqualified, and stands opposed to the relative, often as its negation; i.e., as that which is independent of relation. At various times, principally in METAPHYSICS, it has been used to describe time, space, value, truth and God, or the totality of what really exists as a unitary system somehow both generating and explaining all apparent diversity. It is associated with IDEALISM.

absolute space and time—The view that space and time exist independently of the objects and events in them. This was NEWTON'S position which was rejected by EINSTEIN, among others.

absolutist/relativist debate—Relativism is the position that there is no one correct view of things. Relativists argue that views vary among individual people and among cultures ('cultural relativism'), and that there is no reliable way of deciding who is right. This contrasts with absolutism, the view that there is an objectively right view. Although the most common relativist views concern morality, these terms also apply to ONTOLOGY and the question of the nature of reality itself. Ontological relativists hold that there is no external fact about what sorts of basic things exist: we decide how to categorize things, and what will count as basic, depending on the context and manner of thinking that suits us. By contrast, absolutists hold that there is a basic SUBSTANCE which characterizes the unity of reality (i.e. LEIBNIZ'S 'simple substances' or 'monads'). See RELATIVE TRUTH/RELATIVISM.

acquaintance and description, knowledge by—Popularized by RUSSELL, the terms used to describe two ways in which objects are known. According to him, we have 'acquaintance' with anything of which we are directly aware (namely sense data). This is to be distinguished from knowledge by description, which includes our knowledge of those whom we would normally call our acquaintances. In the normal sense, I would claim to be acquainted with a colleague; but according to Russell, my colleague is for me the body and mind connected with certain sense data.

ad hoc—Latin, 'to this', i.e., 'specially for this purpose'. An *ad hoc* assumption isone that is introduced illicitly in an attempt to save some position from a contrary argument or counter example, intending to show that the position is false. It is illicit because it is designed especially to accommodate the argument or example, and has no independent support.

aesthetics—From the Greek *aisthesis,* 'sensation'. This term, which was coined by Baumgarten in the eighteenth century, has come to designate not the whole domain of the sensible, but only that portion to which the term beauty may apply. In a more general and contemporary sense, it refers to the philosophical study of art, of our reactions to it, and of similar reactions to things that are not works of art. Typical questions here are: What is the definition of art? How can we judge aesthetic worth? Is this an OBJECTIVE matter?

a fortiori—Latin, 'from the stronger'. A phrase used to signify 'all the more' or 'even more certain'. If all men are mortal, then *a fortiori* all Englishmen—who constitute a small sub-class of all men—must also be mortal.

agent—One who acts, or has acted, or is contemplating action. In ETHICS, it is usually held to be a moral agent, i.e., one to whom moral qualities may be ascribed and treated accordingly. The agent is generally a normal (even ideal) adult: free and responsible with a certain degree of maturity, rationality and sensitivity.

alchemy—The ancient art and science of transmutation; the precursor to modern CHEMISTRY and metallurgy. It is also a mystical art (see MYSTICISM for the transformation of consciousness, symbolized by the transmutation of base metals into gold or silver. Drawing on the Hermetic tradition and Greco-Egyptian ESOTERIC teachings, alchemy assumed its historical form by AD 4, but it did not spread throughout Europe until the twelfth century.

algebra—The study of mathematical structure. Elementary algebra is the study of NUMBER systems and their properties. Algebra solves problems in arithmetic by using letters or SYMBOLS to stand for quantities and includes CALCULUS, LOGIC, the theories of numbers, equations, FUNCTIONS and combinations of these.

algorithm—A systematic procedure for carrying out a computation; any step-by-step method for the solution of a particular type of problem.

analysis of variance (ANOVA)—A statistical method (see STATISTICS) for making simultaneous comparisons between two or more means. An ANOVA yields a series of values (*F* values) which can be statistically tested to determine whether a significant relation exists between the experimental variables.

analytic/synthetic—These terms were introduced by KANT, referring to the difference between two kinds of judgement. Kant called a judgement analytic when the 'predicate was contained in the subject'; thus, for example, the subject bachelors contains the predicate unmarried. Some might hold that this distinction is better made in terms of sentences: a sentence is analytic when the meaning of the subject of that sentence contains the meaning of the predicate (i.e. is part of the definition of the subject). In other words, an analytic sentence is one that is true merely because of the meanings of the words. A synthetic truth is a sentence that is true but not merely because of the meaning of the words. 'Pigs don't fly' is true partially because of the meaning

of the words, of course, but since the definition of pigs says nothing in the first case about flying, the sentence is synthetically true. An analytically false sentence is also possible as in 'There is a married bachelor'.

In another sense, a statement is an analytic truth or falsehood if it can be proved or disproved from definitions by means of only logical laws, and it is synthetic if its truth or falsity can be established by other means. This was the distinction postulated by FREGE, and followed by the logical positivists (see POSITIVISM) for whom all the truths of mathematics and LOGIC are analytic.

analytic philosophy—A term covering a variety of philosophical schools which emphasize language and share the view that the primary function of philosophy is to clarify statements. It is usually associated with English-speaking philosophers, and is contrasted with speculative or continental philosophy. Some philosophers have regarded it as opposed to METAPHYSICS but others have held metaphysical views. This includes RUSSELL, who was one of its earliest adherents when the distinction first arose in the first decades of this century.

anthropometry—Literally, the measurement of man, in terms of anatomical height, girth, width, length, etc.

anti-realism—See REALISM.

a priori/a posteriori—Latin, 'from before/from after'. In the early eighteenth century, knowledge was called a priori if it was acquired by reason, not observation, or by DEDUCTION, not INDUCTION. It is a posteriori if it can be known on the basis of, and hence, after, sense-experience of the fact. The terms are associated with KANT who claimed that a priori knowledge can be known independently of any (particular) experience, i.e., every event has a CAUSE.

Archimedes—(*c.* 287–212 BC) Greek mathematician, physicist and inventor; gener ally regarded as the greatest mathematician of antiquity. His rigorous geometrical technique of measuring curved lines, areas and surfaces anticipated modern CALCULUS. He also laid the foundations of mechanics, statics and hydrostatics.

Archimedes' axiom—The order AXIOM for the real line that states that if a, and b are real NUMBERS such that $a < b/n$ for all natural numbers n, then $a \leqslant 0$, or equivalently, that for any positive a and b there is a positive integer n such that $a < nb$, and thus that every real number is less than some natural number. This is equivalent to the assertion that the real numbers are conditionally complete. An infinitesimal is non-Archimedean as it is less than any positive non-zero number.

Aristotle—(384–322 BC) Profoundly influential Greek philosopher and scientist. He was PLATO'S student; like his teacher, he was centrally concerned with knowledge of reality and of the right way to live. Unlike Plato, however, he accepted the reality of the EMPIRICAL, changing world, and attempted to discover what sort of understanding we must have in order to have knowledge of it. He argued that individual things must be seen as belonging to kinds of things, each of which has essential properties (see ESSENTIALISM) that give it potential for change and development. Investigation into the essential properties of humans can tell us what human good is: he conceived it as a life lived in accord with the moral and intellectual

virtues. Although he is recognized for beginning the systematic study of LOGIC, Aristotle's writings cover diverse areas in NATURAL SCIENCE and philosophy.

artificial intelligence (AI)—An area of study in computer science and psychologythat involves the building (or imaging) of machines, or programming computers, to mimic certain complex intelligent human activities. AI is of philosophical interest in so far as it might shed light on what the human mind is like, and in so far as its successes and failures enter into arguments about MATERIALISM.

assertion—FREGE introduced the assertion sign to indicate the difference between asserting a PROPOSITION as true and merely naming a proposition (i.e. in order to make an assertion about it, that it has such and such consequences, or the like). RUSSELL and WHITEHEAD adopted the sign in approximately Frege's sense, and from this source, it has come into general use. Russell requires that the sign be followed by a formula denoting a proposition (see DENOTATION), or a truth value, while Frege requires that it be followed by the syntactical name of such a formula. Some recent writers omit the sign, either as understood, or on the grounds that the distinction is illusory.

attribution theory—In social psychology, the study of the factors that determine how people in everyday life situations come to assign CAUSES, particularly for their own actions and those of others, and the HYPOTHESES arising from that study. The analysis of action as analogous to experimental methods, was first suggested by HEIDER, who remains influential on this theory.

Austin, J(ohn) L(angshaw)—English (Oxford) philosopher; a leading figure in ORDINARY LANGUAGE PHILOSOPHY. He drew philosophical conclusions from analyses of our uses of language in general, and of philosophically relevant words.

automaton/automaton theory—From the Greek *automatos,* 'self-moving'. An automaton is a physical mechanism which exhibits seemingly goal-directed behaviour, but is generally construed to be mindless, a mere machine governed by the laws of physics and mechanics (i.e. a robot). The theory holds that living organisms may be considered machines which primarily abide by mechanistic laws. In METAPHYSICS, this theory is also known as automatism and holds that both animal and human are automata. It was propounded by DESCARTES who considered the lower animals to be pure automata, and man, a machine controlled by a rational soul. Pure automatism for both man and animal was advocated by LA METTRIE (1748), and combined with EPIPHENOMENALISM, found its way into the nineteenth century, in the work of Hodgson, HUXLEY and Clifford.

axiom—A basic statement for which no proof is required, and is a starting point, or premiss, for deriving other statements. An axiomatic theory is one in which all the claims of the theory are presented as theorems derivable from a specified collection, the set (or system) of axioms, which are the axioms of the theory. Axioms are often considered self-evidently true, as those of Euclidean GEOMETRY were for a long time, or as constituting and/or contributing to an implicit definition of its terms.

Ayer, A(lfred) J.—English philosopher, known mainly for his work in EMPIRICISM and linguistic analysis. He rejected METAPHYSICS and

confined the function of philosophy to analysis. His *Language, Truth and Logic* (1936) presented logical POSITIVISM in a rigorous and influential way.

Bacon, Francis—English philosopher and scientist. He was also a legalist and political figure (Baron Verulam [1618] and Viscount St Albans [1620]). Best known for his work on scientific method, he is often considered the father of modern science. In his attempts to establish a 'first philosophy', an axiomatic body of truth as the foundation of science, he sought to restore man to mastery over the natural world.

Barthez, Paul Joseph—French physician who introduced the VITALISM principle in 1778.

Bayesian probability—The Bayesian approach to philosophical problems of scientific method is based on the observation that belief is not a simple yes or no matter, but involves gradations. Its fundamental principle can be stated as follows: the degrees of belief of an ideally rational person conform to the mathematical principles of PROBABILITY theory. According to this view, many methodological puzzles (see METHODOLOGY) arise from a preoccupation with all or nothing belief and may be resolved by means of a more inclusive probabilistic LOGIC of partial belief.

behavioural science—A general label pertaining to sciences that study the behaviour of organisms including psychology, sociology, social anthropology, ethology and others. It is often used as synonym for social science.

behaviourism—Early in the twentieth century, many psychologists decided that introspection was not a reliable basis for a science of the mind; instead they decided to concentrate only on external, observable behaviour. METHODOLOGICAL (psychological) behaviourism is the view that only external behaviour should be investigated by science (see METHODOLOGY). METAPHYSICAL or analytical behaviourism is the philosophical view that public behaviour is all there is—that this is what we are talking about when we refer to mental events or characteristics in others, and even ourselves (see METAPHYSICS). It is a form of MATERIALISM, J.B.WATSON and B.F.SKINNER were two American psychologists who were very influential in arguing the first viewpoint.

Bell inequality—The mathematical condition that expresses the principle of no HIDDEN VARIABLES. It was theorized by John Bell in the early 1960s and refers to the lack of full agreement between QUANTUM MECHANICS and a particular class of hidden variable theories. It is a component of 'Bell's theorem' which promoted philosophical questions about hidden variables to the level of experimental verifiability (although it remained difficult to conceive of specific experiments that could be undertaken in order to demonstrate their VALIDITY). The inequalities in question derive from attempts to account for spin CORRELATIONS between particles: if one is up, the other must be down. The difference between such a theory and quantum mechanics is that in the former, the spins are predetermined (by the hidden variables) before any measurement, and hence, are objectively real.

Bergson, Henri—French philosopher. Dynamism characterizes his philosophy; his dualist view posits a vital principle *(élan vital)* in contrast to inert matter; (see DUALISM); he rejects mechanistic or materialistic approaches to understanding reality and any deterministic view of the world, and claims that the creative urge, not natural selection, is at the heart of evolution (see

MECHANISM, MATERIALISM, DETERMINISM). He draws a distinction between the CONCEPT and the experience of time; the former might be subjected to the kind of analysis applied to the concept of space, but 'real time' is experienced as duration and apprehended by INTUITION. He championed the latter against rationalistic 'conceptual' thought.

Berkeley, George—Irish philosopher, Bishop of Cloyne; known for his empiricist and idealist METAPHYSICS and EPISTEMOLOGY. He rejected the idea that a world independent of perceptions can be inferred from them (see EMPIRICISM, IDEALISM, INFERENCE); mental PHENOMENA, the mind and its contents (spirit and idea), are all that exists. These may be external to us, in the universal mind of God, with the ideas it contains constituting the natural world. His views may be construed as a form of PHENOMENALISM.

Bernard, Claude—French physiologist, who established physiology as an exact science and laid the foundations of experimental method in that field.

Bernoulli, Jean—Swiss mathematician; an important figure in the development of the CALCULUS.

Berzelius, Jöns Jacob—Swedish chemist, recognized for determining the direction of CHEMISTRY for nearly a century. Educated in medicine, he brought organic nature within the atomic concept, while maintaining a vitalist position. See VITALISM.

Bohr, Niels—Highly influential Danish theoretical physicist. He formulated the QUANTUM theory of the electronic structure of the hydrogen atom and of the origin of the spectral lines (corresponding to the energy transition levels) of hydrogen and helium. Bohr became the Director of the Institute for Theoretical Physics in the University of Copenhagen, which rapidly became a mecca for physicists from all over the world. A major development of his philosophical views was put forth in a 1927 lecture when he introduced the idea of COMPLEMENTARITY. He pointed out the impossibility of any sharp separation between the behaviour of atomic objects and their interaction with the measuring instruments which define the conditions under which the phenomena appear. This tended to promote a more realistic interpretation of unobservable conditions.

Bohr's principles—See COMPLEMENTARITY, CORRESPONDENCE.

Bohr's theory—A pioneering attempt to apply QUANTUM theory to the study of atomic structure (1913). It postulates an electron moving in one of certain discrete circular orbits about a nucleus with emission or absorption of electromagnetic radiation, necessarily accompanied by transitions of the electron between the allowed orbits (see ELECTROMAGNETISM). This revised the classical electrodynamic model in which the electrons would theoretically irradiate, lose energy and spiral into the nucleus. Although it was soon shown to be false, Bohr's theory was successfully extended far enough over the next twelve years to suggest that many facts in physics and CHEMISTRY might be explained in these terms, and even led to the modern theory of QUANTUM MECHANICS. Thus, even though it has been superseded, it revolutionized theoretical physics and is today of outstanding historical and philosophical interest.

Boltzmann Ludwig—Vienna-born and educated physicist. He is celebrated for his contribution to the kinetic theory of gases and to statistical mechanics, the

latter of which he was the founder. His great talents as a theoretical physicist focused primarily on the kinetic theory of gases, PROBABILITY THEORY and ELECTROMAGNETISM. The beginning of his career in 1866 belonged to the most creative and revolutionary period in physics since NEWTON, two centuries earlier.

Boltzmann, constant—When the ENTROPY of a system, a gas for example, is divided by the natural LOGARITHM of its statistical instability, the result is the constant named after Boltzmann. It is symbolized by *k*.

Bolyai, Johann—Hungarian mathematician, who at the age of 22 wrote 'Absolute Science of Space', a complete system of GEOMETRY. He showed that EUCLID'S parallel postulate was not necessary. Although he was one of the founders of non-Euclidean geometry, he had been preceded (unknown to him) by GAUSS and LOBACHEVSKY.

Boole, George—English mathematician responsible for the development of the idea of treating variables in LOGIC in ways analogous to those in ALGEBRA; this was the first real step in the development of modern logic. He was one of the first mathematicians to realize that SYMBOLS of operation could be separated from those of quantity. He showed that classes or sets could be operated on in the same way algebraic symbols or numerical quantities can and applied ordinary algebra to the logic of classes.

Born, Max—German physicist who made fundamental contributions to QUANTUM MECHANICS. He invented matrix mechanics and put forward the statistical interpretation of wave function.

Boring, Edwin Garrigues—American psychologist, who won distinction for his *History of Experimental Psychology* (1929), which traces the genesis of this recent academic discipline from its origins in early nineteenth century philosophy and physiology.

Boyle, Robert—English chemist and physicist. He gave clear qualitative expression to the notion of heat as due to an increase in the motion of the particles of a gas. He is also known for advancing an atomistic theory according to which the ultimate constituents of matter were made up certain primitive, simple and perfectly unmingled bodies, which by combining together gave all the natural variety of matter.

Bradley, F(rancis) H(erbert)—English idealist philosopher, known for his works on LOGIC, METAPHYSICS and ETHICS. Outside the British empiricist tradition, his work is more in the continental Hegelian spirit. His central metaphysical notion is 'the ABSOLUTE'—a coherent and comprehensive whole that harmonizes the diversity and self-contradictions of appearances.

Brouwer, Luitzen Egbertus Jan—Dutch mathematician, the founder of mathematical INTUITIONISM, who did important work in the philosophy of MATHEMATICS.

Bruno, Giordano—Italian philosopher and supporter of the Copernican (heliocentric) system. He was arrested by the inquisition and burned at the stake for his radical scientific and religious views.

Büchner, Ludwing—German philosopher, who through his book *Power and Matter,* made MATERIALISM a popular doctrine in central Europe. He opposed DUALISM, claiming that the soul is merely a function of the brain.

Cabanis, Pierre Jean Georges—French physician and philosopher, who pioneered physiological psychology.

calculus—An abstract system of SYMBOLS, with definitions, AXIOMS and rules of INFERENCE, aimed at calculating something. A calculus is interpreted when its symbols are given meaning by relating them to things in the real world, and some philosophers think of the various sciences as interpreted calculi. Questions of completeness, consistency, decidability and criteria for decisions are among the theoretical considerations of this subject. There are many different kinds of calculus and each symbol system of symbolic LOGIC may be called a calculus: sentential or propositional, quantifier or predicate calculus, as well as the calculus of identity, of classes and of relations. Infinitesimal calculus, an invention of NEWTON and LEIBNIZ in the second half of the seventeenth century, is one of the greatest achievements in the history of mathematics. It is based on the concepts of limits, convergence and infinitesimals (variables which approach zero as a limit). See PROPOSITIONAL/ PREDICATE CALCULUS.

Carnap, Rudolf—German-born philosopher who taught at the universities of Vienna, Prague and Chicago. He transplanted logical POSITIVISM when the VIENNA CIRCLE disbanded in pre-World War II Austria. He is important for his work on formal LOGIC, philosophy of SCIENCE and their applications to the problems of epistemology, and helped to develop a new science of logical SYNTAX and SEMANTICS. He espoused the doctrine of PHYSICALISM and sought to construct one common unified language for all branches of empirical science so that problems of language would no longer be an impediment to knowledge.

Cartesian doubt—A philosophical method associated with DESCARTES in which one begins by assuming that any belief which could be doubted is falseeven the most ordinary assumptions of common sense. One then searches for a starting point that is indubitable.

Cartesian plane—A two-dimensional flat plane, the points of which are specified by their position relative to orthogonal axes. It is named after DESCARTES, who established the plane and its coordinates as a basis for analytic geometry.

causality—The principle that every effect is a consequence of an antecedent CAUSE or causes. For causality to be true it is not necessary for an effect to be predictable since uncertainty about it may be attributed to the fact that the antecedent causes may be too numerous, too complicated or too interrelated for analysis. In QUANTUM theory, the classical CERTAINTY of causality is replaced at the sub-atomic level by probabilities that specific particles exist in specific positions and take part in specific events. This involves the uncertainty principle which states that the position and MOMENTUM of an electron cannot be established precisely and it is only following consecutive observations of what may be two particles, that probabilities may be determined. See PROBABILITY.

cause—From the Latin *causa*. A term correlative to the term 'effect'. That which occasions, determines, produces or conditions an effect; or is the necessary antecedent of an effect. Long-standing philosophical problems are concerned with the nature of cause, and how we go about establishing it. HUME argued

that we think that *A* causes *B* when *A's* have regularly been followed by *B's* in the past (i.e. have been 'constantly conjoined' with *B's*); but the notion that *A* has a 'power' to produce *B* 'necessarily', is not something we can observe, such that this is not a legitimate part of the notion of cause. It is argued that this fails to distinguish between causal connections and mere accidental (contingent), but universal regularities.

certainty—From the Latin *certus*, 'sure'. The alleged indubitability of certain truths, especially of LOGIC and mathematics. The concept of certainty plays an important role in the philosophy of DESCARTES, where it applies to a belief or proof which is beyond rational doubt, as in the case of the *COGITO*.

ceteris paribus—Latin, 'other things being equal'. This expression is used in comparing two things, assuming they differ only in the one characteristic under consideration. For example, it could be said that, '*ceteris paribus*, a simple theory is better than a complicated one'; though if everything else is not equal—if, for example, the simpler theory has fewer true predictions—then it might not be better.

(The Great) Chain of Being—A metaphor for the order, unity, and completeness of the created world, thought of as a chain extending from God to the tiniest particle of inanimate matter. The idea has a long history, originating with PLATO'S *Timaeus* and forming the basic medieval and Renaissance image for a hierarchical arrangement of the universe. It is also the title of a book written by Arthur Lovejoy (1873–1962) in 1936, which traces, from Plato onwards, the 'principle of plenitude'—the notion that all real possibilities are realized in this world.

chance—This is an uncalculated and possibly incalculable element of existence concerned with its contingent as opposed to necessary aspects. For example, something happens by chance when it is not fully determined by previous events—when previous events do not necessarily bring it about, or make it the way it is; in other words, when it is a random event. Sometimes, however, we speak of chance events as those we are unable to predict with certainty, though they might be determined in unknown ways. We can sometimes know the PROBABILITY of chance events in advance. See NECESSARY/CONTINGENT TRUTH, RANDOMNESS.

channel—In communications, a specified band of frequencies, or a particular path, used in the transmission and reception of electric signals. See COMMUNICATION THEORY.

charge—A property of some elementary particles that causes them to exert forces on one another, in terms of positive and negative (the natural unit of negative charge is that possessed by the electron and the proton has an equal amount of positive charge). Like charges repel and unlike charges attract each other. The force is thought to result from the exchange of PHOTONS between the charged particles. The charge of a body or region arises as a result of an excess or defect of electrons with respect to protons.

chemistry—The scientific discipline concerned with the investigation of many thousands of substances which exist in nature or can be made artificially (synthetic chemistry). Traditionally, it is subdivided into various branches with specific concerns: physical (dealing with the physical laws governing chemical behaviour); organic/inorganic (the study of substances containing/

not containing carbon); nuclear or theoretical (applications of statistical and QUANTUM MECHANICS); analytic (the detection and estimation of chemical species) and micro-chemistry, a breed of the former (where minute amounts are involved).

circular definition/reasoning—A definition is circular (and thus, useless) when the term to be defined, or a version of it, occurs in the definition; for example, the definition of 'free action' as 'action that is freely done'. Circular reasoning defends some statement by assuming the truth of that statement. It is also known as 'begging the question'.

Clarke, Samuel—English philosopher who championed a Newtonian philosophy in opposition to the prevailing CARTESIAN climate of thought in the Cambridge of his day. In a famous correspondence with LEIBNIZ, he maintained that space and time were INFINITE homogenous entities, as against Leibniz's claim that they were ultimately relational.

Clausius, Rudolf Julius Emmanuel—German theoretical physicist. He ratified Carnot's theory of THERMODYNAMICS which was shown to be inconsistent with the rapidly developing mechanical theory of heat. Preceding Thomson's equivalent formulation, he held that Carnot's theorem could be maintained provided that heat could not by itself pass from one body to another at a higher temperature. As a result, he developed a precise mathematical expression of the second law of thermodynamics in 1854, and later coined the term ENTROPY to express the law of dissipation of energy in terms of its tendency to increase. In 1858, he introduced the important concepts of mean free path and effective radius of a molecule which was later taken over by MAXWELL. Clausius was able to show that these concepts accounted in principle for the observed small values of diffusion rates and heat conductivities in gases in spite of the very large mean speeds of the gas molecules. This theory based on the laws of dynamics and PROBABILITY theory, provided a significant contribution to the kinetic theory of gases. He was one of the most original physicists of the nineteenth century.

Cogito—Latin, 'I think'. An argument of the type employed by DESCARTES *(Meditation IF)* to establish the existence of the self. His *Cogito, ergo sum* ('I think, therefore I exist') is an attempt to posit the existence of the self in any act of thinking, including even the act of doubting. It is not so much INFERENCE as a direct appeal to INTUITION, but it has commonly been construed as an argument, because of Descartes' formulation.

cognition—From the Latin *cognitio,* 'knowledge' or 'recognition'. The term refers both to the act or process of knowing and the knowledge itself. Competing theories of knowledge are the subject matter of EPISTEMOLOGY.

cognitivism—Any theory that deals with COGNITION scientifically. Also known as cognitive science, it is an umbrella term for a cluster of disciplines including cognitive psychology, EPISTEMOLOGY, linguistics, computer sciences, ARTIFICIAL INTELLIGENCE, mathematics and NEUROPSYCHOLOGY. As a new approach to psychological problems, usually making use of experimental data, cognitivism attempts to create theories adequate to explain cognitive processes. In that it uses mental concepts, it constitutes a break from BEHAVIOURISM which has come to be viewed as incomplete in the study of cognition.

communication theory—See INFORMATION THEORY.

complementarity—The principle which states that a system, such as an electron, can be described either in terms of particles or in terms of wave motion. According to BOHR these views are complementary. An experiment that demonstrates the particle-like nature of electrons will not also show their wave-like nature, and vice versa.

computation, theory of—See COMPUTATIONALISM.

computationalism—In psychology, this refers to the use of computers as models of human functioning, and to the extended notion that human COGNITION is a computational process of the sort typified by a standard digital computer. See CONNECTIONIST/COMPUTATIONAL PARADIGM.

computer modelling—A method of transferring a relationship or process from its actual situation to a computer. Computer models are selective approximations of a real situation which, because of their simplification, allow those aspects of the real world which are under examination to appear in a generalized form.

Comte, Auguste—French philosopher, the founder of positivistic philosophy. He began his first series of public lectures on POSITIVISM in 1826, the first volume of which appeared in 1830. He traced the development of human thought from its theological and metaphysical stages to its last positive stage: the systematic collection and CORRELATION of observed facts and abandonment of unverifiable speculation about first CAUSES and final ends. He is credited with having coined the terms altruism and sociology.

concept/conceptualism—While some philosophers conceive of a concept as a mental entity, it is generally regarded as the meaning of a word or phrase, as in the 'concept of man'. Conceptualism is a theory about the nature of UNIVERSALS as mental representations. For instance, a universal term such as animal, is not *merely* a word which applies to a number of particular animals, nor a special kind of entity, a 'universal' which exists outside the mind. It does indeed stand for an entity, but an ideational one which exists only in the way that concepts exist.

confirmation theory—This is closely associated with VERIFICATION theory, although it is concerned with the truth of scientific hypotheses, rather than statements. Many philosophical doctrines (e.g., scientific EMPIRICISM) hold that a certain hypothesis is said to be confirmed to a certain degree by a certain amount of evidence. It depends upon inductive reasoning: the fact that every known *A* is *B* confirms the hypothesis that every *A* whatever is *B*, but does not establish it conclusively, since it is possible that some as yet undiscovered *A* is not *B*, and thus that the unrestricted generalization is false. Evidence in this case merely confers PROBABILITY and the degree of confirmation is thus dependent upon the bulk and variety of the evidence. CARNAP has made elaborate attempts to develop comprehensive formal theories of confirmation on the basis of such principles. See HYPOTHESIS, INDUCTION.

connectionist/computational paradigm—'Connectionism' is Edward Thorndike's term for the analysis of psychological phenomena in terms of association between, not ideas, but situations and responses. Working within a PARADIGM of this sort, recent connectionist theory portrays cognitive activity as information exchanges within a network of interconnected nodes,

studied in terms of the FEEDBACK characteristics of such systems. It may provide an alternative to the DETERMINISM of the computational paradigm which bases its study of human cognitive activity on the basis of a digital computation without environmental interaction.

conservation, laws of—These laws deal with the conservation of mass and energy and relate to the principle that in any system the sum of the mass and the energy remains constant. It follows from the special theory of RELATIVITY and is a general statement of two classical laws. The principle of conservation of energy states that the total energy in any system is constant, while the principle of the conservation of mass states that the total mass of any system remains constant. According to the general principle of conservation it is held that mass and energy are interconvertible according to the equation $E= MC^2$, EINSTEIN'S law.

constructivism—The view that mathematical entities exist only if they can be constructed (or, intuitively, shown to exist), and that mathematical statements are true only if a constructive proof can be given. It is thus opposed to any view that sees mathematical objects and truths existing or being true independently of (our) apprehension (i.e. PLATONISM). Constructivism encompasses INTUITIONISM, FINITISM and FORMALISM.

contingent truth See NECESSARY/CONTINGENT TRUTH.

continuity in nature, laws of—That by which variable quantities passing from one magnitude to another, pass through all the intermediate magnitudes without passing over any of them abruptly. Many philosophers have asserted the probable conformity of natural operations to this composite law, but Boskovich went so far as to prove it a universal law. Thus, the distances or velocities of two bodies can never be changed without their passing through all the intermediate distances or velocities. The movement of the planets are said to abide by these laws, as well as magnetism, electricity, the passage of time, and strictly speaking, all things in nature.

control engineering—The field of engineering concerned with the establishment of objectives for the manipulation of a system's resources in a rapidly changing environment so that command objectives, in the interests of maintaining the system, may be implemented.

conventionalism—Any doctrine according to which A PRIORI truth, or the truth of PROPOSITIONS (or of sentences) demonstrable by purely logical means, is a matter of linguistic or postulational convention (and thus not ABSOLUTE in character). It entails the view, first expressed by POINCARÉ and developed by MACH and DUHEM, that scientific laws are disguised conventions reflecting the decision to adopt one of various possible descriptions.

Copernicus, Nicolas—Polish astronomer. Architect of the heliocentric theory of the solar system, Copernicus found it necessary to retain seventeen of PTOLEMY'S epicycles, while supposing that planetary orbits were circular. The later work of Tycho Brahe and KEPLER dropped these entirely and transformed the orbits into ellipses.

correlation—In STATISTICS, this is a relationship between two or more variables such that systematic increases in the magnitude of one variable are accompanied by systematic increases or decreases in the magnitude of the other. More loosely, it refers to any relationship between things such that

some concomitant or dependent changes in one (or more) occur with changes in the other(s). Note that in both of these usages one properly withholds the presumption of CAUSALITY between the variables. Correlations are statements about concomitance; they may suggest but do not necessarily imply that the changes in one variable are producing or causing the changes in the other(s).

correlation coefficient—A number that expresses the degree and direction of relationship between two (or occasionally, more) variables. The correlation coefficient may range from -1.00 (indicating a perfect negative correlation) to +1.00 (indicating a perfect positive correlation). The higher the value either negative or positive the greater the concomitance between the variables. A value of 0.00 indicates no correlation; changes in one variable are statistically independent of changes in the other. A large number of statistical procedures exists for determining the correlation coefficient between variables, depending on the nature of the data and their methods of collection. See STATISTICS

correspondence—The principle due to BOHR which states that since the classical laws of physics are capable of describing the properties of macroscopic systems, the principles of QUANTUM MECHANICS, which are applicable to microscopic systems, must give the same results when applied to large systems.

co-variance/co-variation—Co-variation is a literal synonym for co-variance which refers to changes in one variable being accompanied by changes in another.

covering law—A general law applying to a particular instance. The covering law theory of explanation states that a particular event is explained when one or more covering laws are given that (together with particular facts) imply the event. For example, we can explain why a piece of metal rusted by appealing to the covering law that iron rusts when exposed to air and moisture, and the facts that this metal is iron, and was exposed to air and moisture. See 'DEDUCTIVE-NOMOLOGICAL MODEL'.

cybernetics—From the Greek *kubernētēs,* meaning 'steersman'. The science of systems of control and communication in animals and machines in terms of FEEDBACK mechanisms. The term was coined by WIENER to designate this field of study, which was a burgeoning interdisciplinary movement led by him in the 1940s. It initially involved mathematics, neurophysiology and CONTROL ENGINEERING, but expanded to include MATHEMATICAL LOGIC, AUTOMATION THEORY, psychology and socioeconomics.

Darwin, Charles—The great English naturalist who gave shape to his evolutionary HYPOTHESIS in *The Origin of Species* (1859). He was not the first to advance the idea of the kinship of all life but is memorable as the expositor of a provocative and simple explanation in his theory of natural selection. He served to establish the fact of evolution firmly in all scientific minds.

Dedekind, Julius William Richard—German mathematician. His major contribution is the 'Dedekind Cut', which allows irrational NUMBERS to be defined in terms of rational numbers, marking the place and filling in the gaps between the set of rational numbers as points on a straight line. It implies that the number series is compact and continuous.

deduction/induction—From the Latin *de,* 'from', and *in* 'in', combined with *ducere* 'to lead'. In an outdated way of speaking, deduction is reasoning from the general to the particular and induction is reasoning from the particular to the

general. In a more contemporary way, the distinction between them is made as follows: correct deductive reasoning is such that if the premisses are true, the conclusion must be true; whereas correct inductive reasoning supports the conclusion by showing only that it is more probably true. A common form of induction works by enumeration: as support for the conclusion that all p's are q's, one lists many examples of p's that are q's. It also involves 'ampliative argument' in which the premisses, while not entailing the truth of the conclusion, nevertheless purports good reason for accepting it.

deductive-nomological model—This mode of explanation takes the form of the logical derivation of a statement depicting the phenomenon to be explained (explanandum) from a set of statements specifying the conditions under which the phenomenon is encountered and the laws of nature applicable to it (explanans). It is also known as the 'COVERING LAW' method of explanation.

De Morgan, Augustus—English mathematician and logician; a noted teacher and founder of the London Mathematical Society. He wrote on PROBABILITY, trigonometry and PARADOXES. De Morgan's rule is used in SET THEORY.

denotation/connotation—The denotation or reference of a word is what that word refers to—the things in the world that it 'names'. By contrast, the connotation or sense of a word is its meaning. Thus, a word can have connotation but no denotation: 'unicorn' has meaning but no reference. The distinction is synonomous with EXTENSION/INTENSION. See also SENSE AND REFERENCE.

Descartes, René—French philosopher and mathematician, the founder of modern philosophy. Earlier scholasticism saw the job of philosophy as analysing and proving truths revealed by religion; Descartes' revolutionary view was that philosophy can discover truth. His famous recipe for doing this is the method of systematic doubt; this is necessary to begin the search for the 'indubitable' foundations for knowledge, the first of which is the truth of his own existence as a thinking (not a material) thing. Although he was a champion of mechanistic thinking about the external and material world, and in fact contributed substantially to the new science and mathematics, he was a DUALIST, and believed that minds are non-material. See MECHANISM.

descriptions, theory of—RUSSELL'S attempt to show how a definite description can have meaning even when there is nothing that answers to that description. How, for example, can one say meaningfully 'The present King of France is bald'? A non-Russellian analysis of the sentence would attempt to isolate a non-existent individual and predicate baldness of him, giving rise to a descriptive FALLACY. It renders the sentence meaningless because, having failed to perform an act of reference, the sentence could not be said to be either true or false. Russell's strategy is to move the definite description out of the position which it occupies, i.e., that of the subject of the PROPOSITION. So, for 'the present King of France is bald', Russell would substitute, 'There is at least one individual which is at present a King of France, and there is at most one individual which is at present a King of France, and that individual is bald'.

determinism—From the Latin *determinare,* 'to set bounds or limits'. The view that every event has previous CAUSES, such that given its causes, each event must

have existed in the form it does. There is some debate about how (and whether) this view can be justified. The view that at least some events are not fully caused is called 'indeterminism'. Determinism is usually a PRESUPPOSITION of science; KANT thought it was necessary; but quantum physics holds that it is false. One of the main areas of concern about determinism arises when it is considered in connection with or in contrast to free will.

dualism/monism—These terms characterize views on the basic kind(s) of things that exist. Dualists hold that there are two sorts of things, neither of which can be understood in terms of the other. In particular, 'dualism' often refers to the view in the philosophy of mind in which the two distinct elements are the mental and the physical. By contrast, monists believe in only one ultimate kind of thing. While the term dualism was initially introduced in 1700 by Thomas Hyde to characterize the good-evil conflict, the term monism was introduced by Christiann Wolff in a discussion of the MIND/ BODY PROBLEM.

Duhem, Pierre Maurice Marie—French theoretical physicist.

Du Bois Reymond, Emil—German physiologist, pioneer of the study of the electric phenomena of living tissues.

Durkheim, Emile—French positivistic sociologist. Influencing French sociology in an EMPIRICAL direction, he stressed the importance of the group as the origin of the norms and goals of individuals, and the source and reference of religious symbols. The function of religion in his view is the creation and maintenance of social solidarity. See POSITIVISM.

Eddington, Sir Arthur Stanley—English astronomer and physicist. He is celebrated for his pioneering work on stellar structure (1926) and for his attempts to unify general RELATIVITY and QUANTUM MECHANICS, with a marked ability to convey complex mathematical ideas to the layperson.

effector—Generally, a muscle or gland at the terminal end of an efferent neural process which produces an observed response or effect.

efferent/afferent nervous system—Efferent is from the Latin, meaning 'carry away from'. Hence, in neurophysiology it refers to the conduction of nerve impulses from the central nervous system outward toward the periphery (muscles, glands). Efferent neurons and neural pathways carry information to EFFECTORS and are called motor neurons or pathways. The afferent nervous system, by contrast, refers to the conduction of nerve impulses from the periphery (the sense organs) the central nervous system.

Einstein, Albert—German-born theoretical physicist whose major contribution was the theory of RELATIVITY. He was educated in Zurich and in 1901 he completed his studies, became a Swiss citizen, and made his first contribution to physics. This was followed in 1905 by three important papers: one was on Brownian movement and provided the most direct evidence for the existence of molecules; another dealt with the spectrum of radiation and provided the basis of QUANTUM MECHANICS; and one presented the special theory of relativity. The fundamental paper on general relativity came in 1915, and was followed by a Nobel prize for his work on quantum theory in 1922. He taught in Zurich, Prague and Berlin, but in 1932 found himself in the United States where he spent the rest of his life, eventually becoming a citizen and holding

a position at the Princeton Institute of Advanced Study. See QUANTUM FIELD THEORY.

electromagnetism—One of the four fundamental FORCES of nature characterized by the FIELDS produced by the elementary charged particles, i.e. protons and electrons. More generally, it is also one of the main branches of physics, linking the phenomena of electrostatics, electric currents, magnetism and optics into a single conceptual framework. The final form of the theory was devised by MAXWELL and is one of the triumph of the nineteenth century science. See CHARGE.

elementary number theory—A branch of pure mathematics concerned generally with the properties and relationships of integers.

elementary proposition—In WITTGENSTEIN'S philosophy these are possible concatenations of simple elements which feature 'states of affairs'. They are composed of strings of names which are ISOMORPHIC to the concatenations of the objects they represent. An elementary PROPOSITION is true, if the objects it mentions are concatenated the way it pictures them, otherwise it is false and the state of affairs does not obtain. The SYNTAX of elementary propositions thus mirrors the geometry of states of affairs.

emotivism—A position in meta-ETHICS that holds that ethical utterances are to be understood not as statements of fact that are either true or false, but rather as expressions of approval or disapproval and invitations to the listener to have the same reactions. HUME might be construed as holding a form of emotivism; in this century, the position is associated with AYER and the American philosopher STEVENSON.

empirical—Relating to sense experience and experiment; having reference to actual facts. In EPISTEMOLOGY, empirical knowledge is not innate, but is knowledge we get through experience of the world; thus it is A POSTERIORI. In scientific method, it is that part of the method of science in which the reference to actuality allows an HYPOTHESIS to be erected into a law or general principle. It is contrasted with NORMATIVE which means regulative or constituting an ideal standard.

empiricism—From the Greek *empeiria,* which is from *empeiros,* meaning 'experienced in', 'acquainted with', 'skilled at'. The doctrine that the source of all knowledge is to be found in experience. One of the major theories of the origin of knowledge, empiricism is usually contrasted with rationalism, the doctrine that reason is the sole, or at least the primary, source of knowledge. Although this term is associated with the denial of innate CONCEPTS and a SYNTHETIC A PRIORI, in general it refers to stressing the role of experience instead of pure reason in the acquisition of knowledge.

entropy/negentropy—Entropy is the measure of the proportion of total energy within a closed system that is available for useful work. If part of the system is hotter than another part then work can be done as the heat energy passes from the hotter to the colder part; but if the temperature is relatively consistent throughout, the system is incapable of accomplishing work. This property follows from the second law of THERMODYNAMICS in that, as a result of irreversible changes to a system in which it expends energy, its capacity to produce additional work decreases and its entropy thereby increases. The absolute value of the entropy of a system—which remains an

arbitrary zero with only changes in its value being significant—is a measure of the unavailability of its energy.

Negentropy is also known as negative entropy and thus refers to the absence of entropy. While entropy is a measure of a relative lack of information, negentropy corresponds to its presence. In the form of structure, it means the departure from the random arrangement of a system's components, to an orderly situation in which is it capable of productive work. See RANDOMNESS.

epiphenomenalism—Theory of the body-mind relation which holds that consciousness is, in relation to the neural processes which underlie it, a mere epiphenomenon, or 'by-product'. This view was advanced by Clifford, HUXLEY and Hodgson.

epistemology—From the Greek *episteme,* 'knowledge' or 'science', and *logos,* 'knowledge'. This term designates the theory which investigates the origin, structure, methods and VALIDITY of knowledge. It is one of the main branches of philosophy. Among the central questions studied here are: What is the difference between knowledge and mere belief? Is all (or any) knowledge based on sense perception? How, in general, are our knowledge claims justified?

EPR experiment—The 1935 work of EINSTEIN, Podolsky and Rosen (EPR) which concluded that QUANTUM theory did not constitute a 'complete' theory, the necessary condition of which, according to EPR, being that 'every element of the physical reality must have a counterpart in the physical theory'. The concept of reality was defined with the claim that if we can predict the value of a physical quantity with certainty (i.e., with PROBABILITY equal to unity) and without in any way disturbing a system, then there exists an element of physical reality corresponding to this physical quantity. The EPR experiment can be criticized on the ground that 'the system' must be understood in its totality and cannot refer to just one of the particles of a two-particle system. A measurement of one of them does indeed disturb the system and alters the quantum mechanical description. Thus, motivated by the EPR argument one may ask whether it is possible to formulate a theory in which physical quantities do have OBJECTIVELY real values 'out there', independently of whether any measurements are made.

equivocation—From the Latin *aequia-vox* meaning 'same name'. Any FALLACY arising from the ambiguity of a word, or of a phrase playing the role of a single word in the reasoning in question, the word or phrase being used at different places with different meanings. The INFERENCE drawn is formally correct if the word or phrase is treated as being the same word or phrase throughout.

esoteric/exoteric—From the Greek *esotero*, 'inner'/'interior', and *exoterikos,* 'outside'. The first implies belonging to the inner circle of initiates, or experts, an exclusive system (i.e., the esoteric doctrines of the Stoics, or the esoteric members of Pythagorean brotherhoods). It is contrasted with exoteric, which connotes that a doctrine or system is open to the public.

essence/essentialism—Essentialism may apply to PLATO'S philosophy of the Forms, but more generally, it is the metaphysical view dating back to ARISTOTLE, maintaining that some objects—no matter how described—have essences;

that is they have, essentially or necessarily, certain properties, without which they could not exist or be the things they are. There is also a related view, originally presented by Locke, that objects must have a 'real'—though as yet unknown—'essence', which (causally) explains their more readily observable properties (or 'nominal essence'). Recently, essentialist considerations have been applied to problems raised in LOGIC and to issues in the philosophies of science and of language. See also METAPHYSICS, CAUSE.

ethics—From the Greek *éthikos,* which is from *ethos,* meaning, 'custom' or 'usage'. As employed by ARISTOTLE, the term included both the idea of 'character' and that of 'disposition'. *Moralis,* a term which was considered equivalent to *éthikos,* was introduced by Cicero. Both terms imply connection with practical activity. It is widely understood that ethical behaviour concerns acting in terms of the good and the right, and the philosophical analysis known as ethics tended to centre on these terms.

ethnomethodology—A term originally coined by GARFINKEL to describe the study of the 'resources' available to participants in social interactions and how these are utilized by them, focusing on the practical reasoning processes that ordinary people use in order to understand and act within the social world. The term is generally used to apply to a body of sociological and psychological research on conversational rules, negotiation of property rights and other socially motivated interactions.

Euclid of Alexandria (3rd century BC).—Greek mathematician, founder of Euclidean geometry and probable founder of the Alexandrian School of geometry. For over 2,000 years his work in geometry held unlimited VALIDITY. Even with the development of non-Euclidean systems of geometry, Euclid's work retains great mathematical importance. In modern mathematics, Euclidean space can have any number of dimensions where the distance between two points is interpreted in the same way as that in two or three dimensions. See 'GEOMETRY, EUCLIDEAN'.

explanandum/explanans—See DEDUCTIVE-NOMOLOGICAL MODEL.

extension—From the Latin *ex,* 'out', and *tendere,* 'to stretch'. The extension of something is its dimensions in space. Having extension is characteristic of things composed of extended SUBSTANCE. Mental substance is unextended since it has no spatial dimensions.

extension/intension—In contemporary LOGIC, 'extension' is sometimes used synonymously with 'DENOTATION', and 'intension' with 'connotation'. The extension of a CONCEPT—a term or a predicate—is the set of things to which that concept applies, while its intension is its meaning in the sentence. An extensional context is a referentially transparent context. This occurs in a sentence where the substitution of an expression does not affect the truth value of the sentence: (1) a singular term *a,* where *b* for *a* have the same denotation; (2) a predicate *F* where *G* for *F* have the same extension; (3) a sentence *p,* where *q* for *p* have the same truth value. Contexts which are not extensional, due to the substituted concept's different meaning in the context, are intensional and opaque. For an example, see OPACITY AND TRANSPARENCY, REFERENTIAL.

fallacy—From the Latin *fallacia,* 'deceit', 'trick' or 'fraud'. Any unsound step or process of reasoning, especially one which has a deceptive appearance of

soundness or is falsely accepted as sound. The unsoundness may consist either in a mistake of formal LOGIC, or in the suppression of a premiss whose unacceptability might have been recognized if it had been stated, or in a lack of genuine adaptation of the reasoning to its purpose. There are many recognized kinds of fallacies. For examples, see *AD HOC,* DESCRIPTIONS, THEORY OF, EQUIVOCATION, MODAL LOGIC, *POST HOC.*

fallibilism—A doctrine of the pragmatist Charles Pierce that ABSOLUTE CERTAINTY, exactitude, or universality is available in no area of human concern or enquiry, but that movement towards these characteristics is available in every case.

family resemblance—By analogy with the ways members of a family resemble each other, this is the sort of similarity that things classified into certain groups share: each shares characteristics with many but not all of the others, and there are no necessary or sufficient conditions for belonging in that classification. WITTGENSTEIN argued that many of our CONCEPTS are family-resemblance concepts, such that they cannot be defined by necessary and sufficient conditions. His best-known example is the concept of a game.

Faraday, Michael—English physicist, the main architect of classical field theory. His work was rejected by his contemporaries and was only later made respectable by MAXWELL. See FIELD.

feedback, positive/negative—While all operating systems function through input and output couplings, feedback is the process of returning a fraction of the output energy or information to the input by producing a corresponding variation between them. Positive feedback occurs when deviation from a stable state produces outputs that lead to yet further deviation, i.e., when an increase in population which produces a greater increase in subsequent generations. With negative feedback, by contrast, the input energy is decreased. It is like a regulatory restraint which tends toward stabilizing the system, as in HOMEOSTASIS.

fideism—The view of Abbé Louis Bautain (the nineteenth-century French Catholic philosopher) that faith precedes reason with respect to knowledge of God, and that in this respect reason is metaphysically incompetent. The doctrine was condemned in an 1855 decretal. See METAPHYSICS.

field—A region under the influence of some physical agency, such as the electric field resulting from an electric CHARGE.

finite—See INFINITE/FINITE.

finitism—An approach to mathematics that admits to its domain only a FINITE number of objects (numbers), each of which must be capable of construction in a finite number of steps. Any general theorem that asserts something of all members of the domain is acceptable only if it can be proven, in a finite number of steps, to hold of each particular member of the domain. HILBERT was the major proponent of finitistic methods in mathematics.

force—Any action that alters or tends to alter a body's state of rest or velocity.

formal/truth/logic—In the traditional use, formal truth means valid independently of the specific subject matter; having a merely logical meaning. In the narrower sense of formal LOGIC which works by exhibiting, often in symbolic notation, the logical form of sentences, it means independent of, without reference to meaning. See VALIDITY, SYMBOLS.

formalism—The tendency to emphasize form as over against content. In ETHICS, the term is sometimes used as equivalent to INTUITIONISM, and is often used to designate any ethical theory, such as KANT'S in which the basic principles for determining our duty are purely formal. In mathematics, formalism refers to a programme of deriving all of mathematics from the smallest possible number of AXIOMS by rules of formation and rules of INFERENCE.

formal/material mode of discourse—The distinction put forth by CARNAP to eliminate the necessity of experience in evaluating the truth of statements. By the formal mode he meant a discourse that confined itself to statements and did not try to go beyond these in reference to things, as in the case of the object sentences of the material mode.

Frege, Gottlob (1848–1925). German logician and philosopher of language, the founder of modern MATHEMATICAL LOGIC. He is best known for inventing QUANTIFICATION in logic, for his arguments that mathematics should be understood as an extension of LOGIC, and for his investigations into the relation between SENSE AND REFERENCE in the philosophy of LANGUAGE.

function—Loosely speaking, a correspondence between one group of things and another. The notion is used in arithmetic, where for example, y is said to be a function of x in the formula $y=x^2$. In its applications in LOGIC, the input value (in place of x in this case) is called the 'argument' of the function, and the output (the corresponding value of y) is called the 'value' of the function for that argument. For instance, given the argument 3, the value is 9.

functionalism—In philosophy, this is an approach to the study of mind that views mental states as functional states. Functionalism in this sense is distinguished metaphysically from PHYSICALISM in that rather than arguing that two identical mental states are physically identical, it argues that they should (can) only be viewed as functionally equivalent. In psychology, this is a general and broadly presented point of view that stresses the analysis of mind and behaviour in terms of their functions or utilities rather than contents.

Galilei, Galileo (1564–1642). Italian astronomer and natural philosopher. Among his scientific discoveries are the isochronism of the pendulum, the hydrostatic balance, the principles of dynamics, the proportional compass and thermometer, and although he did not invent it, he is famous for radically improving the telescope. With the aid of this instrument, he described the mountains of the moon, the Milky Way as a vast constellation of stars, the satellites of Jupiter, the phases of Venus and the so-called solar spots. He is also well-known for his innovative work on gravity and the interdependence of motion and FORCE.

Garfmkel, Harold—American sociologist. He is the founder of ETHNOMETHODOLOGY.

Gassendi, Pierre—French philosopher, scientist and mathematician. He argued the impossibility of deriving scientific theory from sensory experience and held an atomistic theory of the universe; but he is principally known for his fifth set of objections to DESCARTES' *Meditations* (1642).

Gauss, Karl Friedrich—German mathematician and astronomer, considered one of the most original mathematicians who ever lived. He was famous for his contributions to number theory, geometry and astronomy. He was first to prove the fundamental theorem of ALGEBRA and was a pioneer in

non-Euclidean GEOMETRY, STATISTICS and PROBABILITY, the theory of FUNCTIONS and the geometry of curved spaces.

genus/species—For philosophers, not just biological hierarchical divisions, but divisions of group and sub-group anywhere. A genus is a general classification; a species subdivides the genus. This nomenclature is especially associated with ARISTOTLE, who thought that a species ought to be defined, by giving the essential characteristics of its genus, plus the *differentia* (Latin, 'difference') that distinguish that species from others in the genus.

geometry, Euclidean—The geometry based on the assumptions of EUCLID and dealing with the study of plane geometry (two-dimensional) and space or solid geometry (three-dimensional). His AXIOMS were developed in *Elements* which was the pre-eminent textbook on the subject for over 2,000 years; it was not until the nineteenth century that the possibility of a non-Euclidean geometry was seriously considered. See GEOMETRY, NON-EUCLIDEAN.

geometry, non-Euclidean—Any geometry not based upon EUCLID'S assumptions; in particular, the substitution of a postulate different from 'Euclid's parallel postulate' which said that one and only one line can be drawn through a point outside a line and parallel to the line. Until the nineteenth century, this was accepted as a self-evident truth. The replacement of the postulate (as in spherical and pseudo-spherical geometry) and the development of new geometries led to a new look at the basic assumptions on which mathematics is built. The founders of non-Euclidean geometry were GAUSS, Riemann, BOLYAI and LOBACHEVSKI.

Gödel, Kurt—Czech-born American mathematical logician who proved a number of fundamental mathematical results that bear his name; in the course of these proofs he showed the unattainability of the aims of HILBERT'S PROGRAMME and (on some interpretations) LOGICISM, and brought about a complete reassessment of the foundations of mathematics. Gödel's theorem is the proof of the existence of formally undecidable PROPOSITIONS in any FORMAL system of arithmetic. See MATHEMATICAL LOGIC.

Harré, Rom (Horace Romano)—New Zealand-born philosopher of SCIENCE and social and BEHAVIOURAL SCIENCES, who currently teaches at Oxford.

Hartley, David—British philosopher and physician. He developed an account of mind based on sound-like vibrations which is highly important in the history of psychology. He used this not only to explain transmission of messages in the nervous system, but also association of ideas by a kind of resonance, as when one vibrating string activates another by sympathy.

Heider, Fritz—Swiss-born social psychologist who also lived in Germany and the United States, where he emigrated in 1930. His main work, *The Psychology of Interpersonal Relations* (1958), was an influential and wide-ranging phenomenal enquiry which sought to explicate how we discern meaning in everyday events and contributed to the development of ATTRIBUTION THEORY.

Helmholtz, Herman Ludwig Ferdinand von (1821–94).—German scientist, one of the most versatile of the nineteenth century. He is celebrated for his contributions to physiology and theoretical physics.

Hempel, Carl Gustav (1905-). German-born and -educated philosopher who also studied mathematics and physics, and taught in the United States. He became a representative of logical POSITIVISM with its EMPIRICISM and scientific

framework and is known for his 'COVERING LAW' approach which allowed for statistical explanations. These use probabilistic laws to show that the event to be explained is made highly probable, rather than deductively necessitated, by the explanatory premisses. See DEDUCTION, PROBABILITY, STATISTICS.

Hempel's paradox—The PARADOX, developed by Hempel, which deals with the way in which an observation report confirms a generalization. Observing a black raven ought to confirm the HYPOTHESIS that all ravens are black; equally, observing a non-black raven ought to confirm the hypothesis that all non-black things are non-ravens; yet the second hypothesis is logically equivalent to the first, so observation of a white shoe ought to confirm that all ravens are black. But intuitively, it does not. This is one of the difficulties formal CONFIRMATION THEORY meets.

heuristic—From the Greek *heuriskein,* 'to discover'. Serving to find out, helping to show how the qualities and relations of objects are to be sought. In METHODOLOGY, aiding in the discovery of truth. The heuristic method is the analytic method.

hidden variable—An indeterminate factor of which we are currently ignorant, but which once discovered, would in theory allow for an accurate CAUSAL prediction of the phenomena in question. In QUANTUM MECHANICS, a hidden variable view of matter implies the fundamental CAUSALITY of invisible FORCES at the sub-atomic level.

Hilbert, David—German mathematician. A pioneer, along with PEANO, of the science of axiomatics (see AXIOM). This is the attempt to establish a minimum number of unidentified terms and basic definitions, and from these to deduce rigorously the entire structure of mathematics. Recognizing the assumptions at the basis of EUCLID'S geometry, he shifted its foundation from INTUITION to LOGIC.

Hilbert space—A multidimensional space in which the proper (eigen) FUNCTIONS of WAVE MECHANICS are represented by orthogonal unit vectors.

Hilbert's program—Proposed by Hilbert in 1920 in support of his FORMALISM in the foundations of mathematics, this became a motivating problem of metamathematics, showing by purely syntactic means that finitistic methods could never lead to contradiction. This is equivalent to finding a decision ALGORITHM for all of mathematics, and although it was shown unattainable by GÖDEL'S proof in 1931, the project nonetheless led to the development of proof theory and computability theory. See FINITISM, SYNTAX.

Homans, George C(aspar)—American sociologist and professor at Harvard, whose interests range from sociological theory and applications of anthropology to industrial relations.

homeostasis—A type of FEEDBACK by which deviation from stability is counteracted by adjustment internal to the system itself. It refers to an adaptive process which is evident among biological organisms in the mechanisms regulating body temperature and chemical composition of blood.

Hooke, Robert—English scientist. He is known as one of the most brilliant and versatile scientists of the seventeenth century, surpassed only by NEWTON. His contributions in optics and gravitation were dwarfed by the latter with

whom he engaged in many controversies. His reputation as an inventer of scientific instruments, however, remains unrivalled for that period.

Hume, David—British philosopher, born and educated in Edinburgh, one of the greatest philosophers of all time. A thoroughgoing empiricist, he believed that all our ideas were copies of sense impressions; he argued that many of our notions (such as the continuing 'self, and the necessary connection we suppose exists between CAUSE and effect), since unsupported by perception, are mistaken, and that A PRIORI knowledge must derive merely from logical relations between ideas. He is famous also for sceptical conclusions regarding moral 'knowledge': our ethical reactions, he argued, come merely from the psychological tendency to feel sympathy with others. His scepticism and empiricism were enormously influential in the tradition ANALYTIC PHILOSOPHY.

Huxley, Thomas Henry—British scientist, who was the main supporter of DARWIN, but also a distinguished scientist in his own right. A prolific writer, he produced research papers and books on wide-ranging subjects, mainly zoological and palaeontological, but also geological, anthropological and botanical.

hypothesis/null hypothesis—A tentative suggestion that may be merely a guess or a hunch, or may be based on some sort of reasoning; in any case it needs further evidence to be rationally acceptable as true. Some philosophers think that all scientific enquiry begins with hypotheses. A null hypothesis is one which has been shown to be invalid.

iatrochemistry/iatrophysics—The study of chemical/physical phenomena in order to obtain results of medical value. Iatrochemistry was practised in the sixteenth century, and finds modern equivalents in chemotherapy or pharmacology.

ideal/idealism—From the Greek *idea,* 'vision' or 'contemplation'. Broadly, any theoretical or practical view emphasizing mind (soul, spirit, life) or what is characteristically of pre-eminent value to it. It is the alternative to MATERIALISM, stressing the 'ideal'—supra-or non-spatial, incorporeal, NORMATIVE or valuational, and ideological—over the real—concrete, sensuous, factual and mechanistic. Metaphysical idealism is the view that only minds and their contents really or basically exist—a form of monism; and epistemological idealism is the view that the only things we know (or know directly) are our own ideas. 'Idealism' was first used philosophically by LEIBNIZ at the start of the eighteenth century.

idealism—See IDEAL.

incomplete symbol—RUSSELL'S designation for expressions that disappear upon analysis, giving rise to a logical fiction. For example, if a sentence such as 'There is a possibility it will rain' is represented by 'It is possible it will rain', the possibility is said to have been shown to be a logical fiction. His theory of definite DESCRIPTIONS, he believed, showed such descriptions to be incomplete symbols and enabled him to speak of the supposed reference of a non-referring description as a logical fiction. He also aimed to show that symbols for classes were incomplete and that classes were logical fictions.

individuation—Development or determination of a particular (individual) from its corresponding universal form or general type. The principle of

individuation refers to the CAUSE (such as matter, God or form) of individuation.

in situ—Latin, meaning in its (original) place.

induction—See DEDUCTION/INDUCTION.

inductive-statistical model—A form of explanation holding that we can explain some particular action or event by showing that a statement which predicts it is supported with a high degree of inductive PROBABILITY by some set of antecedent conditions.

inductivism—The view in philosophy of SCIENCE which privileges INDUCTION as a valid method of establishing scientific proof. With the growth of NATURAL SCIENCE philosophers became increasingly aware that a deductive argument can only bring out what is already implicit in the premisses, and hence, became inclined to insist that all new knowledge must come from some form of induction, i.e., an empirically based method of reasoning by which a general law or principle is inferred from observed particular instances. BACON, who believed that the method was infallible if the collection of experimental instances was exhaustive, was the prophet of inductivism. In the twentieth century, analyses of induction have proliferated, and largely due to the work of CARNAP with his concept of 'degree of CONFIRMATION', have coalesced with PROBABILITY theory. See DEDUCTION/INDUCTION, EMPIRICAL, INFERENCE.

inference—From the Latin *in* and *ferre,* 'to carry or bring'. A logical relation that holds between two statements when the second follows deductively from the first. This relation is sometimes called implication, but inference refers to the *act* of inferring, the mode of reasoning involved when moving from one statement to another, which the first statement implies. See DEDUCTION/INDUCTION.

infinite/finite—From the Latin *in,* 'not', and *finis* 'boundary', 'limit', 'end'. Thus, infinite means that without limit, boundary or end. Etymologically, the first term is gained by negation of the latter term, although there are those who would claim that the conception of the infinite is prior to the finite. The infinite has been associated from the start with series of NUMBERS, magnitudes, times and spaces, the endlessness of such series provides one, and the basic, conception of infinity. Yet if one applies the predicates 'finite' and 'infinite' to being, the conception changes; if finite being is limited in extent, properties, etc., infinite being would be unlimited, or perhaps ABSOLUTE, in all of these respects.

infinity, axiom of—An AXIOM of SET THEORY that asserts, in one form or another, that there exists a set with an INFINITE number of members, or that the number of objects in the world is a natural number. The reduction of mathematics to set theory requires the axiom of infinity, which RUSSELL originally and erroneously believed was provable from other accepted assumptions. The axiom is now known to be independent of the other axioms of set theory.

information theory (Also known as **communication theory**)—In CONTROL ENGINEERING, the study treating the problem of transmitting messages: that is, of reproducing at one point either exactly or approximately a message

selected at another point. The meaning of the message is irrelevant to the technical problem, and is to be distinguished from a semantical understanding of communication. It is concerned with the ability to encode, transmit, and decode an actual message selected from a set of possible messages with which the communication system claims to deal. Success in this depends on the quantity of information that has to be processed in a unit of time, measured against CHANNEL capacity. Mathematical tools are developed to enable such measurements to be made and compared. The simplest example would be the selection of one out of two equally likely possibilities (one bit, while one out of four requires two bits, etc.). In general, the selective information content measures the statistical unexpectedness of the event in question. The more improbable an event, the larger its selective information content. This way of measuring was developed by SHANNON who inaugurated the study in 1948.

This theory is strongly interdisciplinary and embraces communication processes of all kinds—in human societies, nervous systems and machines. Psychologists and physiologists now make extensive use of its general ideas and it has become commonplace to regard the impulses that flow along nerve fibres as 'conveying information' (although how these are represented in the brain remains unknown). Nonetheless, information theory provides a valuable conceptual bridge between physiology and psychology.

instantiation theory—In the philosophy of SCENCE, a sub-theory of INDUCTIVISM which holds that a scientific theory is confirmed by instances to it. In this sense, every example under consideration that does not contradict a theory or law is an instance of it. However, the reliability of this theory is problematic due to its reliance on INTUITION and the logical paradoxes it gives rise to. See 'HEMPEL'S PARADOX'.

instrumentalism—The view that one should understand scientific theory in terms of experimental procedures and predictions, stressing means over ends. It holds that theoretical entities do not really exist, and that statements about them do not have truth value; they are actually only instruments, tools or calculating devices to relate observations to predictions. Instrumentalism is also the name of the position associated with PRAGMATISM, especially with Dewey, that emphasizes the way our thinking arises through practical experience and represents a way of coping with our environment.

inter alia—Latin, 'amongst other things'.

introspection/introspectionism—From the Latin *intro,* 'within' and *spectare,* 'to look'. Observation directed on the self or its mental states and operations, either through the direct scrutiny of conscious states and processes as they take place, or the recovery of these upon a retrospective act. The term is the modern equivalent of 'reflection' and 'inner sense' as employed by LOCKE and KANT. In psychology, introspectionism is the standpoint which advocates the introspective method.

intuition—From the Latin *intueri,* 'to look at'. As in vision, intuition involves knowledge by which the object (the self, a conscious state, the external world, a universal, rational truth) is immediately apprehended. It can be apprehended directly and completely, in what it is, or it can be apprehended in its concreteness. In the former the intuitive knowledge is opposed to the discursive, in the latter it is opposed to the abstract.

intuitionism—Any theory that holds INTUITION as a valid source of knowledge, as in the philosophies of DESCARTES, SPINOZA and LOCKE. ETHICAL intuitionism is the position that ethical truths are intuited, while mathematical intuitionism holds that any sort of mathematical entity exists only if it is possible to give a constructive existence proof of it (by producing an example of it or providing a method for producing one). See CONSTRUCTIVISM.

invariance—Generally, characteristic of that which does not change. The term is most often used with the qualifier relative since few things are truly invariant. In the psychological study of perception and learning, those aspects of the stimulus world that display higher degrees of invariance, relative to other aspects, are learned most quickly and easily.

ipso facto—Latin, 'by the fact itself', by that very fact or act, thereby.

isomorphism—From the Greek *iso* 'equal' and *morphé* 'form'. The relevance of this term to philosophy derives from the discipline of mathematics, and is related to the close association between mathematics and LOGIC. Any two groups of entities can be said to be isomorphic when they have the same structure, that is, when by a one-to-one correspondence the elements of one group can be correlated with the elements of the other.

James, William—One of the most important and influential American philosophers whose main contribution came through his *Principles of Psychology* (1890). He espoused a doctrine of radical EMPIRICISM, maintaining that experience consists of a plurality, or multiplicity, of reality (real units). He not only doubted consciousness, like HUME, but denied it, holding that reality was nothing but the stream of OBJECTIVE experiences. See also, LANGE.

Kant, Immanuel—German philosopher, one of the most important figures in the history of philosophy. His epistemological concern was with the 'truths of reason' (for example that everything has a CAUSE). Kant thought that such knowledge was A PRIORI and SYNTHETIC, and that it could be accounted for by the way that any rational mind necessarily thinks. Similarly, he argued that the basis of ETHICS is not EMPIRICAL or psychological. Ethical knowledge can be derived merely from the a priori form any ethical assertion must have: it must be universalizable—that is, rationally applicable to everyone (the categorical imperative). Kant argued that this is equivalent to saying that the basic ethical truth was that everyone must be thought of as an end, never merely as a means. Kant's ethical theory has become a major consideration in contemporary ethics.

Kepler, Johannes—German mathematician and one of the founders of modern astronomy. His three laws of planetary motion state: (1) the orbit of each planet is an ellipse, with the centre of the sun at one focus; (2) the imaginary line joining the centre of each planet with the centre of the sun moves over equal areas of the ellipse in equal periods of time; (3) the time each planet takes to complete its journey around the sun is proportional to the cube of its mean distance from the sun.

Keynes, John Maynard—British economist; the most seminal economist of the twentieth century.

Koyré school—A school of thought in the philosophy of SCIENCE led by the Russian philosopher Alexandre Koyré. He held that the great discoveries of the scientific revolution (from COPERNICUS TO NEWTON) were the

achievements of truth-loving individuals working in isolation. This 'internalist' interpretation stressed theory over practice and developed in contrast to the Marxist interpretation of modern science as the response to the technological needs of an emerging capitalist economy.

Kronecker Leopold—German mathematician who developed algebraic number theory. He was often *in* debate with WEIERSTRASS and Cantor which gave rise to his system of AXIOMS to support a formalist viewpoint. See ALGEBRA.

Kuhn, Thomas—American philosopher and historian of science. He holds that scientific theories develop around basic PARADIGMS or models which are of central importance in interpreting scientific theories (i.e., the model of atomic theory in terms of a solar system). In his book *The Structure of Scientific Revolutions* (1962), he described how the scientific community determines the line between orthodoxy and heresy at any given time, such that change in the orientation of science depends upon convulsions in that community.

La Mettrie, Julian Offray de—French philosopher and physician, known for the MATERIALISM of his books, and mechanistic view of both animals and man.

Lange, Carl Georg—Danish psychologist and materialist philosopher. Working independently of William JAMES, he developed an almost identical theory of emotion, i.e., that emotion consists of the bodily changes evoked by the perception of external circumstances. It is known as the James-Lange theory.

Laplace, Pierre Simon—French mathematician, remembered for his contributions to mathematical physics and celestial mechanics.

language, philosophy, of—The branch of philosophy concerned with meaning, truth and with the force of utterances. To be distinguished from 'linguistic philosophy' which is wider in scope and entails the general belief that philosophical questions may be approached by asking questions about the use of words. In the first sense, the question as to the justifiability of this approach is central (as with AUSTIN and WITTGENSTEIN), as is the use of key terms as not only 'meaning' and 'truth', but 'reference' and 'use' as well. It may also be a study of the nature and workings of language as a subject in its own right, rather than as a means to the solution of further philosophical problems.

language game—WITTGENSTEIN used this concept, in a broad sense, to refer to language and its uses, including the way our language influences the way we think and act. The emphasis here is on the similarity of a language to a game: both are rule-governed systems of behaviour, and the rules vary over times and contexts. Language games include the 'picturing' of facts, the primary purpose of language, but extend beyond this to prayer and praise, cursing, requesting, and ceremonial greeting. There is no point in attempting to reduce the endless kinds of language game to a single pattern. Each must be understood in its own terms.

least action, law of—Principle stating that the actual motion of a conservative dynamical system between two points takes place in such a way that the action has a minimum value with reference to all other paths between the points which correspond to the same energy.

Leibniz, Gottfried Wilhelm von—German scientist, mathematician and philosopher. He was trained in law, diplomacy, history, mathematics, theology and philosophy, and became the most notable thinker of the

seventeenth century. Known for the view that all PROPOSITIONS are necessary in this 'best of all possible worlds', Leibniz's conception of the universe united beauty with mathematical order. He described the vital elements of this world as 'monads' (true atoms that exist metaphysically); their co-existence and relations are regulated by a pre-established harmony, which is the work of God. Leibniz devoted much of his work to the reform of science through the use of a universal scientific language and a CALCULUS of reasoning, a method which was a forerunner to modern symbolic LOGIC. He and NEWTON independently developed the calculus.

Leibniz's law—Also known as 'the indiscernibility of identicals' or its converse 'the identity of indiscernibles', this law states that if x and y are identical, then x has every property y has, and y has every property x has.

Lévi-Strauss, Claude—French structuralist philosopher; known for his application of STRUCTURALISM to anthropology. He investigated the relationship between culture (an exclusive attribute of humanity) and nature, based on the distinguishing characteristic of man: the ability to communicate in a language.

Lewes, George Henry—British psychologist and philosopher. He contributed to the development of EMPIRICAL METAPHYSICS, and stressed introspection in psychology, using both SUBJECTIVE and OBJECTIVE methods; he viewed mind as similar to body, with aspects that can be logically separated yet are not wholly distinct.

Liebig, Baron Justus von—German chemist. An outstanding figure in chemical education, and the greatest chemist of his time.

Lobachevski, Nikolai—Russian mathematician, contemporary of BOLYAI, who also challenged the parallel postulate of EUCLID. He assumed that through a point outside a given line there are at least two lines parallel to the given line. He then constructed a non-Euclidean GEOMETRY in which the sum of the angles of a triangle is not greater than 180°, and the smaller the triangle is in area, the closer to 180° is the sum of the angles.

Locke, John—English philosopher and political theorist. He argued that none of our ideas are innate and therefore all our knowledge must come from experience. This position makes him the first of the three great British EMPIRICISTS (the others are BERKELEY and HUME). Influential also in political theory, he is renowned for his advocacy of (traditional) liberalism and natural rights.

logarithm—The index (exponent) which changes a given number, called the base, into any required number. The solution of the equation $b^x=N$, where b and N are known, is a logarithm.

logic—From the Greek *logos* meaning 'knowledge' as well as 'reason, speech, discourse, definition, principle or ratio'. Generally speaking, something is logical when it makes sense, although more strictly, it refers to the theory of the conditions of valid INFERENCE. The term was first used by Alexander of Aphrodisius (2nd century AD), then developed in ARISTOTLE'S logical writings which were called the *Organon,* or instrument of science. Traditional logic included various sorts of categorization of some types of correct and incorrect reasoning, and included the study of the SYLLOGISM. Most logical theory today is done by exhibiting the types of sentences, and giving rules for what correctly may be reasoned on the basis of sentences of different types, in

symbolic form; that is, with SYMBOLS taking the place of logically relevant words or connections. This logic, which concentrates on reasoning that is correct because of SYNTAX, is deemed FORMAL, and is contrasted with informal logic which analyses arguments semantically, and relies less heavily on symbols and mathematical procedures.

logical atomism—The position, associated with RUSSELL and WITTGENSTEIN, that language might be analysed into 'atomic propositions', the smallest and simplest sentences, each of which corresponds to an 'atomic fact', one of the simplest bits of reality. See ELEMENTARY PROPOSITION.

logical empiricism—A doctrine of meaning holding that a word or sentence has meaning only if rules involving sense experience can be given for applying or verifying it. ANALYTIC sentences are excepted. Such rules may further constitute the meaning.

logical positivism—See POSITIVISM.

logical truth—A sentence is logically true when it is true merely because of its logical structure. It is distinguished from analytically true sentences which are true merely because of the meaning of the words. Logical truths are also called 'logically necessary' sentences, but these should be distinguished from (metaphysically) necessary truths, since some of these are neither analytically nor logically true (i.e. KANT'S belief that 'All events have a cause' is a necessarily true, but not logically nor analytically true). 'TAUTOLOGY' is often used as a synonym for 'logical truth' and sentences that are neither logically true nor logically false—that are merely true or false—are said to be logically contingent truths or falsehoods. See ANALYTIC/SYNTHETIC, NECESSARY/CONTINGENT TRUTH.

logically proper name—A proper name constituting a definite DESCRIPTION of the kind required by Russell's LOGICAL ATOMISM. Such names had meanings that were strictly identifiable with their bearers and were meaningless if their bearers did not exist. RUSSELL thought demonstratives (i.e., 'that' and 'this') were logically proper names. Ordinary names cannot have their meanings strictly identified with their bearers since we associate a variety of descriptions with the proper names we use. They depend upon such descriptions to ensure their meaningfulness.

logicism—The view pioneered by FREGE and RUSSELL, holding that received mathematics, in particular arithmetic, is part of LOGIC. Its aim was to provide a system of primitives and AXIOMS (which upon interpretation yielded logical truths) such that all arithmetical notions were definable in the system and all theorems of arithmetic were theorems of the system. If successful the programme would ensure that our knowledge of mathematical truths was of the same status as our knowledge of logical truths.

Lorentz transformation—This refers to a set of equations for transforming the position-motion parameter from an observer at one point, O (x,y,z), to an observer at O'(x',y',z'), moving relative to one another. The equations replace the Galilean transformation equations of NEWTONIAN MECHANICS in RELATIVITY problems.

Lotze, Rudolf Hermann—German philosopher and psychologist. A mechanist, he elaborated the philosophical system of teleological IDEALISM, and aided in founding the science of physiological psychology.

Lucretius (full name: Titus Lucretius Carus) (96?–55 BC).—Ancient Roman poet/philosopher. He popularized the scientific and ethical views of the atomists who believed that things are composed of elementary basic parts.

Mach, Ernst—Austrian theoretical physicist; the 'father of logical POSITIVISM'. He fundamentally reappraised the philosophy of SCIENCE with his belief that science, partly for historical reasons, contained abstract and untestable models and concepts, and that it should discard anything that is not observable.

Maimonides (or Moses ben Maimon) (1135–1204).—Spanish-born Jewish philosopher and theologian; codifier of the Talmud.

mass—The quantity of matter in a body. It varies with velocity in accordance with the principle of relativity and is controvertible with energy by EINSTEIN'S law.

materialism—Any set of doctrines stressing the material over spiritual factors in METAPHYSICS, value theory, physiology, EPISTEMOLOGY or historical explanation. In its extreme form, it is the philosophical position that all that exists is physical. LUCRETIUS and Hobbes are two of the many philosophers associated with this view. Materialists with respect to mind sometimes argue that apparently non-physical things like the soul, mind or thoughts are actually material things. Central-state materialists identify mental events with physical events central in the body (i.e. the nervous system). Some materialists, however, think that categorizing things as mental is altogether mistaken, that mental events do not exist, and that this mode of discourse should be eliminated as science progresses.

mathematical logic—The application of mathematical techniques to LOGIC, in an attempt both to deduce new PROPOSITIONS by formal manipulations, and to detect any underlying inconsistencies. Its study, by many eminent mathematicians and philosophers, as a means of clarifying the basic concepts of mathematics, has revealed a number of PARADOXES, several of which have yet to be resolved. It is also known as symbolic logic.

mathematics, philosophy of—The study of the concepts and justification for the principles used in mathematics. Two central problems concern what, if anything, mathematical statements such as '2+2=4' are about, and how it is that we come to have knowledge of such statements. Questions as to the origin and nature of our knowledge of them tend to distinguish various positions within the study: realists hold that it derives from the existence of abstract entities, the relations among which mathematical statements describe (also known as PLATONISM); conventionalists hold that such statements are true merely by convention or fiat; intuitionists restrict the scope of mathematical knowledge to that which can be proven by constructive processes alone (also known as CONSTRUCTIVISM); another form of intuitionism is that of KANT who held that this knowledge is self-evident and A PRIORI, logicists, such as FREGE and RUSSELL, who to some extent accept Kant's view, yet are unsatisfied with its SUBJECTIVE bent, hold that our knowledge of mathematical truth, is as certain as that of logical truth; and formalists, like GÖDEL, maintain that mathematical sentences are not about anything, but are rather to be regarded as meaningless marks.

matrix theory—A branch of mechanics that involves the idea that a measurement on a system disturbs, to some extent, the system itself. It originated simultaneously with, but independently of, wave mechanics. It is equivalent to wave mechanics but here the wave functions are replaced by vectors in a

suitable space (HILBERT SPACE) and the observable things of the physical world, e.g., energy, momenta, coordinates, etc., are represented by matrices. A matrix is a mathematical concept introduced originally to abbreviate the expression of simultaneous linear equations. It appears as an array of mn numbers set in m rows and n columns and is a matrix of order $m \times n$.

Maxwell, James Clerk—Scottish physicist, the pioneer of electromagnetism. Mathematically interpreting FARADAY'S concept of the electromagnetic FIELD, Maxwell successfully developed the revolutionary field equations bearing his name. This was an advance that may be ranked in pre-quantal theoretical physics among NEWTON'S dynamics and EINSTEIN'S RELATIVITY. He is also known for his early predictions of the existence of radio waves—the equations of which are fundamental throughout modern telecommunications—as well as, more importantly, his contributions to the kinetic theory of gases. He adopted CLAUSIUS'S concept of mean free path and greatly extended the latter's statistical approach to the subject by allowing for all possible speeds in the gas molecules. This resulted in the celebrated Maxwell distribution of molecular velocities, together with important applications of the theory to viscosity, conduction of heat, and diffusion in gases. He also drew upon the work of BOLTZMANN, who took over his approach.

mechanism—From the Greek *mēkhanē*, 'machine'. The theory that all phenomena are explicable by mechanical principles, with the view that all phenomena are the result of matter in motion and can be explained by its laws. Mechanistic doctrine holds that nature, like a machine, is a whole whose single function is served automatically by its parts. As a theory of explanation by efficient as opposed to final CAUSE, it was first put forth by Leucippus and Democritus (460–370 BC) as the view that nature is explicable on the basis of atoms in motion and the void. It was later developed in the seventeenth century as a mechanical philosophy by GALILEO as well as DESCARTES, for whom the ESSENCE of matter is EXTENSION, and all physical phenomena is explicable by mechanical laws.

Meinong, Alexius Meinong—Austrian philosopher who studied under Brentano and developed the latter's views on the different sorts of 'existence' of the objects of thought. He is known for the view that there are three distinct elements in thinking: the mental act, its content and its object. Object is defined as that towards which a mental act can be directed; it may or may not be an existing entity. Content is that attribute of the mental act that enables attention to be directed toward any part.

Mersenne, Marin—Friend and principal correspondent of DESCARTES. Friar Mersenne, a prolific writer himself, was responsible for collecting for publication the first six sets of objections to the *Meditations*.

metalanguage—A language used in talking about another language. In LOGIC, one distinguishes between the object language and the metalanguage. The first refers to the signs which refer to the world, the language in use, while the latter refers to that part of language which refers to the signs of the language itself. Thus, for example, particular INFERENCES are symbolized in the object language, but general forms of valid inference are symbolized in the metalanguage. See SYMBOLS.

metaphysics—From the Greek 'above' or 'beyond' physics. This term, which refers to one of the main branches of philosophy, is said to have been derived from one of ARISTOTLE'S books, which having followed his book on physics, was deemed The *Metaphysics* by a later editor. Metaphysics is thought of as a study of ultimates, of first and last things, its content going beyond physics, or any other discipline. It tends toward the building of systems of ideas; and these ideas either give us some judgement about the nature of reality, or a reason why we must be content with knowing something less than the nature of reality, along with a method for taking hold of whatever can be known.

methodology—The systematic analysis and organization of the rational and experimental principles and processes which must guide a scientific enquiry, or which constitute the structure of the special sciences more particularly. Also called scientific method, it is usually considered a branch of LOGIC; in fact, it is the application of the principles and processes of logic to the special objects of science; while science in general is accounted for by the combination of INDUCTION and DEDUCTION as such.

Mill, John Stuart (1806–173)—The most influential English philosopher of his time. He is known for his thoroughgoing EMPIRICISM, his development of utilitarianism, and liberal political views, as well as his work on the principles of scientific enquiry. He held that all INFERENCE is basically INDUCTION on the basis of the uniformity of nature from one particular event to another or a group of others. He holds that the conclusion of syllogistic reasoning always involves the inclusion of the premisses, with knowledge of those in turn resting on empirical inductions. He is known for his inductive 'methods of experimental inquiry' which define the CAUSE of an event as the sum total of its necessary conditions positive and negative.

mind/body problem—This involves the question as to the relation between the mental and the physical, i.e., whether they are distinct, or whether events in one can be reducible to those of the other. Until recently most philosophers have held a dualistic view of the relation between mind and body. (See DUALISM). This is in the tradition of DESCARTES who ascribed mental attributes to spiritual substances, logically independent of anything physical, but inhabiting particular bodies in a way not satisfactorily defined. Although attempts are being made to establish a causal affinity between the mental and physical, their theoretical relation remains a problem.

modal logic—The study of the features and relations of sentences which include the following words, and distinctions between types of modal logic: necessary and 'possible' (alethic), 'ought' and 'must' (deontic), 'knows' (epistemic) and 'before' (temporal). The study encompasses the methods of good reasoning involving these sentences in which a modal FALLACY arises when the premisses 'It's necessary that: if p then q' and 'p' are used mistakenly to derive 'It's necessary that q'.

modus ponens—Latin, 'method of putting'. A rule for correct DEDUCTION of the form: 'If p then q; p; therefore q'. It is also called 'affirming the antecedent'.

modus tollens—Latin, 'method of taking'. A rule for correct DEDUCTION of the form: 'If p then q; it's not the case that q; therefore it's not the case that p'. It is also called 'denying the consequent'.

Moleschott, Jacob—Dutch physiologist, a leading representative of scientific MATERIALISM.

Müller, Johannes Peter—German physiologist and anatomist, widely regarded as the founder of modern physiology.

momentum—The product of the mass and velocity of a particle.

monism—See DUALISM/MONISM, NEUTRAL MONISM.

Moore, G(eorge) E(dward) (1873–1958). English (Cambridge) philosopher; the father of ANALYTIC PHILOSOPHY, he also led the revolt against IDEALISM early this century. He was a frequent defender of common sense against abstruse philosophical theory and PARADOX, and for a philosophical method based on clarification and analysis of meanings.

moral statistics—The statistical presentation of regularity in free human acts which are posited under the influence of certain psychic, social, cosmic and other conditions (i.e. STATISTICS on marriage, suicide, crime, birth, automobile accidents). The philosophical meaning of such statistics lies in the fact that they impressively point up the intimate relationship between a person's motive for acting and the psychological/physiological conditions she finds herself in. They demonstrate the impossibility of unmotivated willing, but they do not prove whether or not, in a particular case, a person acted without freedom (a moderate DETERMINISM). The metaphysical question about the freedom of the will cannot be decided by the use of statistical methods.

morality—From the Latin *moralis,* which is equivalent to *éthikos,* meaning 'custom' or 'usage'. One's morality is one's tendency to do right or wrong, or one's beliefs about what is right and wrong, good or evil. In many usages, it is a synonym of 'ETHICS', although the latter term is generally used to designate the philosophical study of these matters. The term was introduced to philosophy by Cicero (106–43 BC), the Roman statesman, orator and political writer.

morphology—From the Greek *morphé,* 'form', and *logos,* 'knowledge'. In biology, this is the study of the form and structure of plants and animals considered apart from function; while in linguistics, it is the formal arrangement and interrelationship of morphemes or the branch of this discipline which studies these, the smallest meaningful units of language.

multiple regression—A technique which determines the optimum weighting of a number of independent variables in order to predict a single dependent variable.

mysticism—From the Greek *mystés* meaning 'one initiated into the mysteries'. A variety of religious practice that relies on direct experience, supposedly of God and of supernatural truths. Mystics often advocate exercises or rituals designed to induce the abnormal psychological states in which these experiences occur. They commonly hold that in these experiences we achieve union with God or with the divine ground of all being.

natural/artificial language—A natural language is one used by an actual group of people, that has developed on its own, culturally and historically. An artificial language, by contrast, is one developed for some purpose. Philosophers use the term to refer especially to ideal languages, the development of which is one of the aims of symbolic LOGIC. Computer languages are also examples of artificial language.

natural science—The collective sciences or any science that deals with the physical universe, such as biology, CHEMISTRY and physics.

necessary/contingent truth—According to conditions of modality (concerning the mode—actuality, possibility, or necessity—in which anything exists) a PROPOSITION is necessarily true if it is certifiable on A PRIORI grounds, or on purely logical grounds. It is a stronger kind of truth than a contingent truth of a proposition which could have been otherwise, but is not as a mere matter of fact. Many philosophers think that the necessity or contingency of some fact is a metaphysical matter—a matter of the way the way the external world is—while others think that this difference is merely a matter of the way we think and conceive of the world—that a truth taken to be necessary is merely a conceptual or logical or ANALYTIC truth. See LOGIC, METAPHYSICS, CONCEPT/CONCEPTUAL.

Neurath, Otto—Austrian philosopher; one of the original members of the VIENNA CIRCLE. With CARNAP, he invented the doctrine of PHYSICALISM, stressing the role of PROTOCOL STATEMENTS, i.e. statements based on observation and referring to SPACE-TIME states.

neuropsychology—A sub-discipline within physiological psychology that focuses on the interrelationships between neurological processes and behaviour.

neutral monism—A theory of mind-body relations, found in the philosophies of JAMES and RUSSELL, which is not dualistic, nor monistic in the conventional sense. According to this theory, minds and bodies do not differ in their intrinsic nature; the difference between them lies in the way that a common ('neutral') material is arranged. This material is not one entity (monism), but consists of many entities (i.e., experiences) of the same fundamental kind.

Newton, Sir Isaac (1642–1727)—Renowned English mathematician and scientist. In his *Mathematical Principles of Natural Philosophy* (1685–87), he not only announced his discovery of the Law of Gravity but also presented a new system of mechanics by which the structure of the universe was to be understood. He sought the true mechanical laws of nature not on the basis of A PRIORI principles but on the basis of the most precise observation of phenomena in nature. One of the important consequences of this work lay in his development of the proper methods of reasoning; he claimed that philosophy's error in seeking the nature of reality was in its insistence on making DEDUCTIONS from phenomena without knowing first the CAUSES of phenomena.

Newtonian mechanics—The basis of Newtonian mechanics consists of three fundamental laws of motion: Law I, every body perseveres in its state of rest or uniform motion in a straight line except in so far as it is compelled to change that state by forces impressed on it (the Principle of Inertia). Law II, the rate of change of linear MOMENTUM is proportional to the force applied, and takes place in the straight line in which that force acts. Law III, an action is always opposed by an equal reaction: the mutual actions of two bodies are always equal an act in opposite directions.

It was Newton's great achievement to have worked out the mechanics of celestial and terrestrial motion which gave modern science a solid basis for the continual development which has since occurred. A more general system

of mechanics has been given by Einstein in his theory of RELATIVITY. This reduces to Newtonian mechanics when all velocities relative to the observer are small compared with those of light.

nihilism—From the Latin *nihil,* 'nothing'. A doctrine denying VALIDITY to any positive alternative, the term has been applied to METAPHYSICS, EPISTEMOLOGY, ETHICS, politics and theology. It is the name of various sorts of negative belief: that nothing can be known, or that nothing generally accepted in science or religion is correct or that the current social order is worthless, or that nothing in our lives has any value.

nomological—From the Greek *nomos* 'law' and *logos,* knowledge'. It is synonymous with 'nomic', meaning having to with law. A nomological regularity is distinguished from a mere (accidental) regularity or coincidence, in that the first represents a law of nature.

normative—Tending to establish a standard of correctness by prescription of rules; evaluative rather than descriptive. Normative ETHICS—any system dictating morally correct conduct—is distinguished from meta-ethics—the discussion of the meanings of moral terms without issuing directives.

number—A concept of quantity. Natural numbers: {1, 2, 3, 4…}; whole numbers: {0, 1, 2, 3, 4…}; integers: {-3, -2, -1, 0, +1, +2, +3}. There is also the set of real numbers which is composed of both rational and irrational numbers: the former are expressed as fractions (i.e., 1/2), while the latter are non-rational, and not expressible as an integer (i.e., 2). A complex number is the sum of a real number and an imaginary one (i.e., 3+2i, where i is imaginary). A cardinal number describes how many members are in a set of things, which could be either INFINITE (i.e. {2, 4, 6,…}) with no last number in the sequence, or finite (i.e., {2, 4, 6, 8}).

null hypothesis—See HYPOTHESIS.

objective—(1) Possessing the character of a real object existing independently of the knowing mind, in contrast with SUBJECTIVE, as that within a subject. (2) In scholastic terminology, beginning with Duns Scotus (1266/74–1308) and continuing into the seventeenth and eighteenth centuries, objective designated anything existing as idea or representation in the mind, without independent existence. The change from sense (2) to (1) was made by KANT, who understood objective as in the first sense.

Occam's razor (or Ockham's)—A general principle of ontological economy that states that, everything else being equal, the correct or preferable explanation is the one that is simpler, i.e., that needs fewer basic principles or fewer explanatory entities. It was named after William of Occam (1285?–?1349), the English theologian whose work was largely in LOGIC and theory of meaning. See ONTOLOGY.

ontology/ontological—From the Greek *ontos,* 'of being' and *logos,* 'knowledge'. The term thus means 'knowledge of being' and refers to the philosophical study of being or existence. Although the relation between METAPHYSICS and ontology is unclear, typical questions which concern the latter are: What basic sorts of things exist? What are the basic things out of which others are composed? How are things related to each other? The ontology of a theory consists of the things which are presupposed by that theory. Simply put, 'ontological' means 'having to do with existence'.

opacity and transparency, referential—The distinction that expresses that Leibniz's law is not universally applicable. For example, 'Cicero' and 'Tully'

have the same reference in that they are two names for the same man. But suppose that someone, *X*, does not know this: then it might be true (a) that Cicero is believed by *X* to have denounced Catiline, and (b) that Tully is believed by *X* not to have denounced Catiline. In other words, although they are the same man, contrary to Leibniz's law, Cicero does not appear to have every property that Tully has. It is usual to call '…is believed by *X* to have denounced Cataline' the context of the use of the term 'Cicero'; in the case considered, the context is said to be 'referentially opaque'. In cases where Leibniz's law is satisfied, the context is said to be 'referentially transparent'. This distinction refers to terms, predicates or PROPOSITIONS and the wider distinction between intensional or extensional contexts which are created upon their removal from a sentence. See LEIBNIZ'S LAW, EXTENSION/INTENSION.

operationism—The view that scientific concepts are to be defined in terms of experimental operations, and that the meaning of these terms is given by these procedures. Operationists argue that any terms not definable in this way should be eliminated from science as meaningless. With respect to QUANTUM physics, this would mean referring to the existence of particles as visual effects which exist under certain conditions, when certain measurements are carried out. However, they are realists in that they hold that the objects science theorizes about are (sometimes) true. It is contrasted with the anti-REALISMM of INSTRUMENTALISM, although they share an emphasis on understanding science in terms of its experimental means.

operator/logical operator—That which effects an operation and in LOGIC is usually expressed as a SYMBOL. Corresponding to each FUNCTION on objects there is a symbolic operation effected by the symbol for that function. Thus, if *f(x)* is a function and *a* an object, *f(a)* is an object—the object generated from *a* by application of *f(x)*. But *'f(a)'* is a name formed by conjoining the symbol *'f'* for the function with the name *'a'*, *'f'* is then an operator on names of objects, and is a name-forming operator; that is, when applied to the name of an object, the result is another name. Logical operators are the truth-functional operators and quantifiers, (see QUANTIFICATION). The former are also called sentential operators because, when applied to sentences, they yield another sentence.

'order from disorder' principle—The idea that all events happen from definite causes, according to definite laws and a certain necessity, if only our knowledge could encompass the full scope of these seemingly random events throughout eternity. It entails reasoning from indeterminacy to determinacy and the methodological movement from CHANCE and PROBABILITY to CERTAINTY. See METHODOLOGY, RANDOMNESS.

ordinary language philosophy—A branch of twentieth-century philosophy (most closely associated with WITTGENSTEIN, AUSTIN and RYLE) that held that philosophical problems arise because of confusions about, or complexities in, ordinary language. These might be solved (or dissolved) by attention to the ways the language is used. Thus, for example, problems about free will might be solved (or shown to be empty) by close examination of the actual use in English of such words as 'free', 'will', 'responsible', and so on.

organizational theory—Generally, this is the sociological study dealing with the patterned behaviour of interacting individuals or groups. More specifically, it may refer to the interaction between people in a particular organization, e.g. in industry, the armed forces, etc. It is usually undertaken with a view to making the organization more efficient and concerns itself with issues like improving relations between management and workers, improving communication channels or improving decision-making procedures.

orientalism—A general designation used loosely to cover the philosophical tradition of the Orient, extending far into antiquity and to some extent characterizing early Greek thinking. Oriental philosophy, though by no means homogeneous, nevertheless shares one characteristic: the practical outlook on life (ETHICS linked with METAPHYSICS), involving an absence of clear-cut distinctions between pure speculation and religious motivation, often combining folklore, folk etymology, practical wisdom, pre-scientific speculation, even magic, with flashes of philosophical insight.

oscillator—A system which rhythmically stores and releases energy at a particular frequency (e.g., an electric circuit in which electrical oscillations occur freely and which is usually designed specifically for this purpose).

paradigm—From the Greek *paradeigma* 'a pattern, model or plan'. A completely clear, typical and indisputable example of a kind of thing.

paradox—A clearly false or self-contradictory conclusion deduced apparently correctly from apparently true assumptions. There are many kinds of paradoxes and philosophers often find principles of wide-ranging importance while trying to discover what has gone wrong in a paradox. There is a whole family of them known as the self-referential paradoxes which has been of particular concern to philosophers and logicians, and some of which have played a crucial role in the historical development of the foundations of mathematics. One example is the well-known statement of a Cretan that 'All Cretans are liars', the Liar paradox, while another is Russell's paradox which had serious repercussions in the theory of classes and thus also in the foundations of mathematics. See RUSSELL'S PARADOX, TYPES, THEORY OF.

parapsychology—The investigation of prescience, telepathy and other alleged psychical phenomena which seem to elude ordinary physical and physiological explanation.

pari passu—Latin, meaning 'with equal pace'; simultaneously and equally.

Pascal, Blaise—French philosopher, mathematician and physicist, who made great contributions to science through his studies in hydrodynamics and the mathematical theory of PROBABILITY. Dissatisfied with experimentation, he turned to the study of man and spiritual problems.

path analysis—The analysis of relationships among a series of variables which attempts to establish a CAUSAL chain between them, usually by the use of MULTIPLE-REGRESSION—a technique which determines the optimum weighting of a number of independent variables in order to predict a single dependent variable. The method is generally presented in path diagrams in which asymmetric (one-way) relations between variables are represented by arrows.

Pavlov, Ivan Petrovich—Russian physiologist and pioneer of the study of conditioning. In his study of digestion which won him a Nobel Prize, he observed that dogs salivated in anticipation of receiving food, a response

which by 1901, he had named a 'conditioned REFLEX'. This became a cornerstone of American BEHAVIOURISM before World War I and is now regarded as a fundamental aspect of learning.

Peano, Guiseppe (1858–1932).—Italian mathematician who made several contributions to MATHEMATICAL LOGIC. He developed a logical system which permits the writing of every PROPOSITION exclusively in SYMBOLS, in an attempt to emancipate the strict logical part of reasoning from verbal language and its vagueness. Among his contributions to the field of mathematics was a postulate system known as Peano's Postulates, from which the entire arithmetic of natural NUMBERS can be derived. See 'PEANO'S ARITHMETIC'.

Peano's arithmetic—This designates Peano's five postulates for the arithmetic of natural NUMBERS. In the first version, the first postulate referred to 1 as the first number, while in the later versions, as here, he began with 0 as the first number: (P1) 0 is a number (P2). The successor of any number is a number (P3). No two numbers have the same successor. (P4) 0 is not the successor of any number (P5). If P is a property such that: (a) 0 has the property *P;* (b) whenever a number *n* has the property *P,* then the successor of *n* also has the property *P,* then every number has the property *p*. The last AXIOM is the famous 'principle of mathematical induction'.

Pearson chi-square (x^2) tests—There are several statistical tests included here, all of the them variations of the basic chi-square statistic (the use of a theoretical model to determine expected results and to gauge the differences between expectation and observation). They are used as tests of the amount of data conformity between a large sample and a population and as tests of association between two samples.

Peirce, Charles Sanders (Santiago)—American philosopher and logician. Very little of his work was published during his life, and his views were, until recently, unknown except in the version popularized by JAMES. Today, however, he is recognized as a metaphysician of considerable power, the father of PRAGMATISM, and a significant contributor to philosophy of SCIENCE and LOGIC.

phenomenalism—Literally, a theory based on appearances. This is a doctrine which holds that the knowledge man can reach is never more than the knowledge of phenomena, because man's limited ability to know necessarily deforms objects according to one's own SUBJECTIVE nature.

phenomenology—A school of philosophy deriving from the thought of Husserl (1859–1938). Phenomenologists generally believe that INTUITIONS or direct awarenesses form the basis of truth, and the foundation on which philosophy should proceed: by introspection, bracketing, and exploration of the 'inner', SUBJECTIVE world of experiences. This takes the form of a phenomenological reduction in which normal assumptions and PRESUPPOSITIONS (particularly those of science and including belief in the external world) are suspended and we attempt to see things purely, as they fundamentally appear to consciousness.

phenomenon—From the Greek *phainomenon,* meaning 'that which appears'. Philosophers sometimes use this term in the ordinary sense, referring merely to something that happens, but often it is used in a more technical way, referring to the way a thing seems to us—to something as we perceive it. It is

contrasted with noumena which are insensible and perhaps rationally ascertainable things as they really are, i.e., things-in-themselves.

photon—The QUANTUM of electromagnetic radiation. For some purposes photons can be considered as elementary particles travelling at the velocity of light. See ELECTROMAGNETISM.

philosophy of mathematics—see MATHEMATICS, PHILOSOPHY OF.

physicalism—Although this term is usually taken to be synonymous with MATERIALISM—which refers to the philosophical position that all that exists is physical—it may also refer to the position that everything is explainable by physics. It constitutes a doctrine of the VIENNA CIRCLE of logical positivists requiring that PROTOCOL STATEMENTS of any HYPOTHESIS be expressed in a physicalistic language.

picture theory—WITTGENSTEIN'S theory of language which holds that the primary purpose of language is to state facts. When a fact is pictured there is a structural similarity between the language used and what is pictured. A secondary purpose of language is to state tautologies, which are true but empty. They tell us nothing but that their use is necessary. The operations of both LOGIC and mathematics are series of tautologies. Any statement which fails to picture a fact, or to express a tautology, is nonsense. Statements of both METAPHYSICS and ETHICS fall into this category. See TAUTOLOGY.

Planck, Max Carl Ernst Ludwig (1858–1947).—German physicist, famous for his enunciation of QUANTUM theory. He introduced the findings of his early work on THERMODYNAMICS into the problem of black-body radiation, in search for a theoretical explanation for the equilibrium reached within a heated cavity based on temperature only, independent of wall density. Drawing upon the relationship between ENTROPY and PROBABILITY put forth by BOLTZMANN, Planck introduced a quantum variable of action *(h)* with a discrete spectrum for radiation into his account. The result was his celebrated formula for radiation density as a function of frequency and temperature, from which he was able to calculate BOLTZMANN'S CONSTANT and his own quantum of action.

Plato (428?–348? BC) Ancient Greek philosopher, student of SOCRATES, possibly the greatest philosopher of all time. His writings, which often take the form of dialogues with Socrates, contain the first substantial statements of many of the questions and answers in philosophy. His best-known doctrine is the theory of the 'forms' or 'ideas': these are the innate, general or perfect versions of characteristics we ordinarily encounter. They are eternal and unchanging and exist independently of any earthly thing that participates in them.

Platonism—Various sorts of views growing from aspects of PLATO'S thought. Platonists tend to emphasize Plato's notion of a transcendent reality, believing that the visible world is not the real world, and Plato's rationalism—that the important truths about reality and about how we ought to live are truths of reason. In the philosophy of MATHEMATICS, Platonism designates the belief that mathematical objects exist independently of our thought; that mathematical statements are true (or false) independently of our ability to prove them; and often includes the view that the subjects of these statements

(NUMBERS) are abstract entities, the relations of which true mathematical statements describe.

pluralism—The view that the world contains many kinds of basic entities, which in their uniqueness cannot be reduced to just one (MONISM) or two (DUALISM). The doctrine of LOGICAL ATOMISM developed by RUSSELL is perhaps the most thoroughgoing pluralism in the history of philosophy.

Poincaré, (Jules) Henri (1854–1912).—French mathematician, engineer and philosopher of SCIENCE. He is often labelled a conventionalist because he argued that the fundamental AXIOMS of geometrical systems express neither A PRIORI necessities nor CONTINGENT TRUTHS, and because he detected important definitional elements in physics. In mathematical philosophy he was an intuitionist, attacking the LOGICISM of RUSSELL and PEANO. See CONVENTIONALISM, INTUITIONISM.

Popper, Karl Raimund—Austrian philosopher of SCIENCE, famous for his emphasis on falsifiability rather than on verifiability in science. This means that the most reliable criterion for truth lies in hypotheses which can be disproved by negative instances. He is also known for his defence of liberalism in social theory. See HYPOTHESIS.

positivism/logical positivism—The philosophy associated with Auguste COMTE, which holds that scientific knowledge is the only valid kind of knowledge, and that anything else is idle speculation. In its earlier versions, the methods of science were held to have the potential not only of reforming philosophy, but society as well. Sometimes this term is loosely used to refer to logical positivism which is a twentieth-century outgrowth of more general nineteenth-century positivism.

post hoc—Latin, 'after that'. A mistaken kind of reasoning, also known as false CAUSE, which states *'post hoc ergo propter hoc'* ('after that, therefore because of that'). It involves the misidentification of x as the cause of y because x happens before y (for example, if one supposed that a falling barometer caused it to rain).

pragmatism/neo-pragmatism—From the Greek *pragma,* 'thing, fact, matter, affair'. A philosophical movement in the nineteenth and twentieth centuries whose emphasis lay in interpreting ideas through their consequences. As a school of philosophy, it is associated mainly with American philosophers in the beginning of the twentieth-century, especially PEIRCE, JAMES and Dewey. Peirce, who adapted the term from KANT in 1878, later called his version 'pragmaticism' in order to distinguish the original philosophy from the neo-pragmatism which was less strictly defined. The early pragmatists emphasized the relevance of the practical application of things, their connections to our lives, our activities and values. They demanded instrumental definitions of philosophically relevant terms, deeming much of the language of METAPHYSICS meaningless, and urged that we judge beliefs on the basis of their benefit to the believer.

praxis—In general this term means 'accepted practice or custom' or 'practical human activity', but more particularly, as it was used by Marx, it refers to the union of theory and practice.

predicate calculus—See PROPOSITIONAL/PREDICATE CALCULUS.

presupposition—Something assumed beforehand, for example, as the basis of an

argument. The statement 'He has stopped drinking excessively' presupposes that at one time he was drinking excessively.

prima facie—Latin, 'at first appearance'. Based on the first impression: what would be true, or seem to be true, in general, or before additional information is added about the particular case. Thus, philosophers speak of *'prima facie* obligations', those things that by and large people ought to do, but that might not be real duties in particular cases, given additional considerations.

private language argument—WITTGENSTEIN'S argument which states that if there were private events we would be unable to categorize or talk about them. In order for it to be possible to name or categorize something, there must exist rules of correct naming and categorization. Without the possibility of public check, there would be no distinction between our feeling that we reported them accurately and our really doing so, such that nothing could count as our doing so correctly or incorrectly. Thus, there could be no such thing as a 'private language'—a language naming private events.

probability—From the Latin *probare,* 'to prove, to approve', which is related to the Greek *eulogon* meaning 'reasonable or sensible'. The term thus refers to the likelihood of the happening of an event, or of the truth of a PROPOSITION. Where conclusions follow by necessity in deductive INFERENCE they follow only by probability in INDUCTION. Probability theory has been developed into a very sophisticated theory in modern mathematics. When probability is represented by a given number, it is usually on a scale from 0 (impossible) to 1 (definite). To say that something is probable may be to say that it has a probability of more than 0.5. There has been philosophical controversy about what it really means to say that an event has a certain probability. Some philosophers argue that saying a die has a probability of $\frac{1}{6}$ of coming up six means that one is justified in expecting it to come up six only to the degree $\frac{1}{6}$, or that this number should measure the strength of this belief.

problem of 'other minds'—The problem which questions the ground (if any) there is for thinking that anyone else has a mind, and is not, for example, just a body with external appearance and behaviour like one's own. It hinges on the fact that a person's mind and its contents can only be 'perceived' by that person who is thus unable to perceive anyone else's. Some philosophers (RYLE, for example) think that the absurdity of this problem shows that there is something wrong with the view of the mental that leads to it.

procedural explanation—A type of explanation that uses simulation to arrive at solutions to problems. Central to this approach is the idea of representational knowledge about the world as procedures within a system. In behavioural science it provides an alternative to causal or quasi-causal modes of explanation. It may also refer to programs in a computer language in which the meanings of words and sentences are conveniently expressed, and the execution of these programs corresponds to reasoning from the meanings.

proposition—From the Latin *proponere,* 'to set forth or propose'. This term has been used in a variety of ways. Sometimes it means merely a sentence or a statement. Perhaps the most common modern use is the one in which a proposition is what is expressed by a (declarative) sentence: an English

sentence and its French translation express the same proposition, and so do 'Steven is Ed's father' and 'Ed's male parent is Steven'.

propositional function—A technical term due to RUSSELL, used to denote that for which a predicate of predicate LOGIC stands. An *n*-place predicate, when complemented by n singular terms, yields a sentence that expresses a PROPOSITION about the objects denoted by those terms. The *n*-place propositional function for which the predicate stands is such that when applied to *n* objects, the result is a proposition concerning those objects. Just as two different sentences may express the same proposition, two different predicates may stand for the same propositional function.

prepositional/predicate calculus—The two logical calculi most commonly encountered. Any FORMAL system of LOGIC can be called a propositional calculus if it consists of a specification of a formal language, the SYMBOLS of which are either propositional variables or connectives (where the latter represent such connectives as 'and', 'or', 'not', 'if…then'), and a set of AXIOMS and/or rules governing the connectives of the language. 'Propositional calculus' usually refers to any system in which the formally VALID arguments can be shown to be valid by application to the standard two-valued truthtable definitions of the logical connectives. It is also known as 'sentential' logic or calculus (see VALIDITY).

Used without qualification, predicate calculus usually means 'classical first-order predicate calculus'. This is the system obtained by extending the axioms and/or rules of propositional calculus by adding similar ones for the quantifiers which are designed to treat universally quantified sentences as INFINITE conjunctions and existentially quantified sentences as infinite disjunctions. It deals with sentences using logical terms such as 'all', 'some', 'no', or 'there exists at least one'. It is also known as 'quantifier' logic or calculus. See QUANTIFICATION, UNIVERSAL/EXISTENTIAL.

protocol statement—A statement consisting of an observation report describing directly given experience or sense data. Also called 'basic sentences', these were regarded by logical positivists of the VIENNA CIRCLE as the basis of all science, and of intelligibility in any field. CARNAP argued that protocol statements can be expressed in the language of physics.

Ptolemy, Claudius—(second century AD) Hellenic scientist and philosopher. His great work in astronomy dealing with all of the planets and 1,022 stars, published around AD 150, held the earth to be a globe in the centre of the world system, and the heavens to make a diurnal revolution around an axis passing through the centre of the earth. This system was accepted until COPERNICUS in the sixteenth century. His philosophy was influenced by Platonism, Stoicism and neo-Pythagoreanism, as well as by ARISTOTLE.

quantification, universal/existential—In traditional LOGIC, quantification is the consideration of the totality of objects under discussion in a statement, which necessarily precedes the assessment of its truth or falsity. Universal quantifier is the name given to the notation *(x)* prefixed to a logical formula *A* (containing the free variable *x)* to express that *A* holds for all values of *x*—usually, for all values of *x* within a certain range or domain of values, which either is implicit in the context or is indicated by the notation through some

convention. Similarly, existential quantifier is the name given to the notation *Ex* prefixed to a logical formula *E* (containing the free variable *x*) to express that *E* holds for some (i.e. at least one) value of *x*—usually, for some value of *x* within a certain range or domain. The *E* which forms part of the notation is often inverted, and various alternative notations also occur.

quantum field theory—A quantum mechanical theory in which particles are represented by FIELDS whose normal modes of oscillation are quantized. Elementary particle interactions are described by relativistically invariant theories of quantized fields. In QUANTUM ELECTRODYNAMICS, for example, charged particles can emit or absorb a PHOTON, the quantum of the electro-magnetic field. Quantum field theories naturally predict the existence of antiparticles and both particles and antiparticles can be created or destroyed; a photon can be converted into an electron plus its antiparticle, the positron. These theories provide a proof of the connection between spin and the STATISTICS underlying the Pauli exclusion principle.

quantum/quanta—From the Latin *quantum,* 'how much'. Used in philosophy to refer to a FINITE and determinate quantity, the term has passed into physics where its reference is to the packets of energy, or quanta, the basic indivisible units of QUANTUM MECHANICS.

quantum electrodynamics—A relativistic theory of QUANTUM MECHANICS concerned with the motions and interactions of electrons, muons and PHOTONS, i.e., with electromagnetic interactions. Its predictions have proven highly accurate.

quantum mechanics—A system of mechanics used to explain the behaviour of atoms, molecules, and elementary particles. In 1901 PLANCK suggested that energy must be radiated in discrete units or quanta. In 1913 BOHR applied this theory to the structure of the atom; later his 'solar system' model of the atom was superseded by the formal equations of Heisenberg and SCHRÖDINGER. These yield the required predictions of the frequency and amplitude of radiation emitted by the atom. But one consequence, the uncertainty principle, discovered by Heisenberg in 1927, is that the variables usually interpreted as specifying the position and the MOMENTUM of sub-atomic particles cannot both take definite values simultaneously. This places severe limits on the degree to which these particles or wave-packets can be interpreted as ordinary spatio-temporal objects. The problem thus becomes a locus of dispute between realist and formalist philosophies of science. In addition the conception of fundamental particles as more like disembodied waves than particles challenges a simple material view of the world.

Quetelet, Lambert Adolphe Jacques—Belgian statistician and astronomer. He was DURKHEIM'S predecessor and the founder of social physics. In his greatest book, *Sur L'Homme* (1835), he showed the use that may be made of the theory of probabilities, as applied to *'l'homme moyen'* or average person.

Quine, Willard Van Orman (1908–)—Contemporary American philosopher, professor at Harvard since 1946. Known primarily as a logician, his interests and important works extend over many of the basic problems in SEMANTICS, EPISTEMOLOGY and METAPHYSICS.

Ramsey, Frank Plumpton—English mathematical philosopher. Expanding upon the logical problems raised by RUSSELL and WITTGENSTEIN, he made a fundamental distinction between *human* LOGIC, which deals with useful

mental habits and is applicable to the realm of practical probability, and *formal* logic, which is concerned exclusively with the rules of consistent thought.

randomness—In common usage something happens randomly when it is not determined by previous events. In PROBABILITY theory, though, in order for an event to be random it must be equally as likely to occur as any other. It defines equiprobability just as it is defined by it. With respect to human action it must be distinguished from arbitrariness as this applies to the random behaviour of unpredictable particles in QUANTUM MECHANICS.

realism/anti-realism—From the Latin *res* meaning 'thing', from which *realitas* is also derived. Realism is, in general, the view that some sort of entity has external existence, independent of the mind. Anti-realists think that that sort of entity is only a product of our thought, perhaps only as a result of an artificial convention. Realists quarrel with anti-realists in many philosophical areas: in METAPHYSICS, about the reality of UNIVERSALS, and in ETHICS, about the reality of the moral categories. Scientific realists sometimes hold that theoretical entities are mind-independent, or that laws in science reflect external realities (i.e. are not merely humanly constructed), or that the universals discovered by science are real and mind independent.

reducibility, axiom of—Russell's axiom, necessary in connection with the ramified theory of types, if that theory is to be adequate for classical mathematics, but the admissibility of which has been much disputed. An exact statement of the axiom can only be made in the context of a detailed formulation of the ramified theory of types, although it might be said that it cancels a large part of the restrictive consequence of the prohibition against impredicative definition, and reduces that theory to the simple theory of types. See TYPES, THEORY OF.

reductionism—The attempt to reduce one science to another by demonstrating that the key terms of the one are definable in the language of the other, and that the conclusions of the one are derivable from the PROPOSITIONS of the other. Reductionism about some notion is the idea that that notion can be reduced—can be given a 'reductive analysis'—and perhaps that it thus can be eliminated. In the social sciences, it operates by holding that social phenomena can be defined in terms of the sum of individuals' behaviour, such that any statement about a social phenomena may be reduced to what individual people do, and social theory may be in principle be reduced to psychology.

reflex/reflex theory—A reflex is an immediate, unlearned response to a specific stimulus. The reflex theory of action was proposed by DESCARTES (1650); Marshall Hall (1833) and CABANIS (1802) were among the first to relate the concept to the nervous system. PAVLOV'S work on reflex-action, which has become a standard topic in psychology, is often associated with reflexology. This is a mechanistic, behaviouristic point of view that argues that all psychological processes may be represented as reflexes and combinations of reflexes. See MECHANISM.

refutation—The demonstration by means of argument that some position is mistaken. This is not merely an attempt at rebuttal, but properly speaking, a demonstration successfully showing that a claim is false or position untenable.

relative truth/relativism—Truth which may vary from individual to individual, group to group, time to time, having no OBJECTIVE standard and usually

implicated in a subjectivistic theory of knowledge. In EPISTEMOLOGY and ETHICS, relativism denotes the theoretical position which emphasizes this kind of truth. See ABSOLUTIST/RELATIVIST DEBATE.

relativity, special/general theories of—The former contains the famous $E=MC^2$ formula, while the latter deals with SPACE-TIME curvature. The special theory of 1905, entails EINSTEIN'S rejection of the notion of an ABSOLUTE SPACE AND TIME. The new view holds that SIMULTANEITY can be established only within a given inertial system, and will not be valid for observers in systems which are in motion relative to the given system. According to this demonstrable theory, mass increases and time slows down as velocity increases, and time is regarded as a fourth dimension. The consequences are such that the same event, viewed from inertial systems in motion with respect to each other will occur at different times, bodies will measure out at different lengths, and clocks will run at different speeds. The general theory of 1916 generalized the results of the special theory from inertial systems to non-linear transformations of co-ordinates. This was necessary in order to account for the proportionality between gravitational mass and inert mass. In the theory, gravitation is reduced to or is an effect of space-time curvature, and depends upon the masses distributed through the universe. Thus, the concept of action at a distance is discarded. Confirmation of the general theory is much weaker than that of the special theory, but the bending of light rays as they pass through a strong FIELD of gravitation has apparently been observed. One consequence of this theory is that the universe is FINITE but unbounded and it is thus consonant with the cosmological picture of an expanding universe.

Royce, Josiah—American philosopher, influenced by Hegel, who developed his own philosophy of absolute IDEALISM. He argued that to have a conception of an orderly continuous world it is necessary to assume that there is an 'absolute experience to which all facts are known and all facts are subject to universal law'.

Russell, Bertrand (Arthur William) (1872–1970). British philosopher. He is perhaps the best-known philosopher of the twentieth century, as well as the founder (with WHITEHEAD) of contemporary symbolic LOGIC. He was also the leader (with MOORE) of the twentieth century revolt against IDEALISM, though some of his views—for example, on our knowledge of externals—tended to be less in accord with common sense than Moore's. Owing to his pacifism, his criticism of Christianity and his advocacy of freer sexual morality, he was a controversial public figure; his views even led him to be fired from teaching positions and jailed.

Russell's paradox—The PARADOX concerned with the set of sets which are not members of themselves (i.e., is a set a member of itself? If it is, it isn't. If is isn't, it is). It has resulted in some complications in set theory. See SET THEORY, TYPES, THEORY OF.

Ryle, Gilbert—English (Oxford) philosopher and leading early figure in ANALYTIC PHILOSOPHY and ORDINARY LANGUAGE PHILOSOPHY. He did important work in philosophy of LOGIC and of mind; in *The Concept of Mind* (1949), his key work, he argued that cartesian DUALISM was based on a category mistake.

Saussure, Ferdinand De—Swiss linguist and philosopher, known for his work on structural linguistics and his influence on contemporary French STRUCTURALISM.

scepticism—From the Greek *skepsis,* 'consideration' or 'doubt'. The view that reason has no capacity to come to any conclusions at all, or else that reason is capable of nothing beyond very modest results. This position questions not so much the truth of a particular belief, but the VALIDITY of the justifications for it. In fact, consistent scepticism is close to agnosticism and NIHILISM. The more extreme sceptics are often called Pyrrhonists, after Pyrrho the founder of the sceptical tradition. HUME is known as a champion of modern scepticism.

Schlick, Moritz (1882–1936).—German founder of the VIENNA CIRCLE, leading figure in the development of logical POSITIVISM. His own view was called 'Consistent Empiricism'.

Schröder, Ernst—German logician and mathematician. He systematized and completed the work begun by BOOLE and DE MORGAN in the ALGEBRA of LOGIC. His contributions to the algebra of relations have particular importance.

Schrödinger, Erwin (1887–1961).—Austrian physicist, born and educated in Vienna. He was the founder of WAVE-MECHANICS and originator in 1926 of the Schrödinger equation describing the QUANTUM behaviour of electrons and other particles. This PRESUPPOSED EINSTEIN'S treatment of light as PHOTONS associated with electromagnetic waves, but taken one step further to the development of a fundamental differential equation which was seen to govern particle behaviour in a wave FIELD. He also proved that this theory was mathematically equivalent to matrix mechanics and along with Heisenberg, BOHR, Pauli and Dirac, played a vital role in the in the creation of modern quantum theory.

science, philosophy of—A discipline which attempts to relate philosophy to the fields of scientific enquiry. Depending upon the philosopher and the area of science, its goal is to discover the nature of science, or the nature of scientific method, or the LOGIC of science, or to explore the interfaces of the fields of science, or to axiomatize the sciences. It involves the question of what constitutes genuine science from pseudo-science, and considers the empirical collection of data and inductive extrapolations, as well as the role of valid explanations, models and theories, and to what extent these correspond to objective reality (realism vs. anti-realism and instrumentalism). Although the philosophy of science extends back to the origins of Western philosophy, when emphasis was on scientific knowledge, it is more appropriate to regard it as beginning with the remarkable development of the sciences in the modern period.

semantics—From the Greek *semantikos,* 'significant meaning', which is from *sema,* 'sign'. Semantics is that part of language which has to do with meaning and reference. The term was first used in a technical sense in philology, where it stands for the historical study, empirically oriented, of the changes of meanings in words. In philosophy, semantics is usually considered as the study and interpretation of formal SYMBOLS. It is concerned with the relations between signs and the objects which they designate, mostly in contrast with SYNTAX which designates the rules of FORMALISM in themselves.

sensationalism—From the Latin *sensatio,* which is from *sentire,* 'to feel or perceive'. Subvariety of EMPIRICISM which asserts that all knowledge is ultimately derived form sensations. Hobbes is considered the founder of modern sensationalism and Condillac is its most typical exponent.

sense and reference—These terms render a distinction drawn by FREGE. The 'sense' *(Sinn)* of an expression is its meaning, as opposed to that which the expression names, its 'reference' *(Bedeutung)*. Expressions can have different meanings, but the same reference: e.g. 'the Morning Star' does not mean the same as 'the Evening Star', but both have the same reference, the planet Venus. The terms are synonomous with connotation and DENOTATION.

sense modality—In BEHAVIOURAL SCIENCE, under the general heading of sense, there are its primary modalities. Five criteria distinguish these: they have (1) different receptive organs, that (2) respond to characteristic stimuli. Each set of receptive organs has (3) its own nerve that goes to (4) a different part of the brain, and (5) the resultant sensations are different on the basis of these criteria. Nine senses have been identified: vision, audition, kinesthesis, vestibular, tactile, temperature, pain, taste and smell.

set theory—Sets (or classes) occur naturally in mathematics, but their importance was only appreciated after G.Cantor (1845–1918) had developed the theory of INFINITE sets. His ideas formed the basis for the LOGIC of FREGE and RUSSELL. The discovery of various PARADOXES showed that the naive theory of classes is contradictory (i.e., sets which are, and at the same time, are not, members of themselves). Cantor himself made a distinction between collections (such as the totality of all abstract objects) which are too all-embracing to be treated as wholes and smaller totalities (such as the set of all real NUMBERS) which can be regarded as single objects; nowadays the former are called proper classes, the latter are called sets.

Shannon, C(laude) E(lwood)—American applied mathematician, engineer and pioneer of COMMUNICATION THEORY.

Sherrington, Sir Charles Scott—British physiologist and philosopher. He did his epoch-making work on the REFLEX response of the spinal cord, with a detailed anatomical study of the structure of the nervous system. It has been said that modern neurophysiology owes not only its basic theories but also its nomenclature to Sherrington. As a philosopher, he was concerned with the 'mind-brain' problem, taking a firmly dualistic line, but imposed on it his own concept of integrative function by which the action of the nervous system is coordinated.

simpliciter—Latin, meaning 'simply'. Without qualification, not just in certain respects.

simultaneity—To be truly simultaneous events must occur not only at the same time but also at the same place. For example, an event on Jupiter might be observed to occur simultaneously with an event on Earth. However, as the two events occur in different frames of reference, and as the information cannot travel from one frame to the other faster than the speed of light, the two events would not, in fact, have occurred simultaneously.

sine qua non—Latin, meaning 'without which not'; indispensable condition or qualification.

Sinn—See SENSE AND REFERENCE.

Skinner, B(urrhus) F(rederic)—American psychologist; the developer of operant-conditioning techniques. He showed that animal and human behaviour could be modified by reinforcement and that animals could in this way be trained to carry out particular tasks to obtain reward, or avoid punishment. These came to be widely used in the training and studying of animals, and in the modification of human behaviour in teaching and clinical situations. He promulgated a philosophy of BEHAVIOURISM.

social anthropology—Also known as cultural anthropology, the study of the culture and social structure of a community or society including its psychological factors. It emphasizes the understanding of the total configuration and interrelationships of cultural traits, complexes, and social relationships in a particular geographic environment and historical context. There has been a tendency in recent years to extend its range of study from non-Western societies to modern Western culture.

sociology—From the Greek *socio,* 'to associate', and *logos,* 'knowledge'. The term is taken to refer to a study of the forms, institutions, functions, and interrelations of human groups. The term was introduced by Auguste COMTE to designate a new science, the most comprehensive of all, dealing with social phenomena. The character he expected of the discipline is suggested by the term 'social physics', his original name for the subject.

Socrates (470?–399 BC).—Athenian philosopher whose debates were chronicled by PLATO. Extremely influential for his 'dialectical' method of debate in which he led his opponents to analyse their own assumptions and reveal their inadequacy. He rejected the sceptical and relativistic views of the professional rhetoricians of the day, urging a return to ABSOLUTE ideals. He was condemned to death for impiety and corrupting the youth.

solipsism—From the Latin *solus,* 'alone' and *ipse,* 'self'. The doctrine that the individual human mind has no grounds for believing in anything but itself. The consequence is sometimes drawn that the mind coming to that conclusion constitutes all there is of reality. The first claim may be termed 'epistemological solipsism', while the latter view, often drawn as a *reductio ad absurdum* of the first, may be called 'metaphysical solipsism'.

space-time—A four dimensional order with four coordinates, three of them spatial (length, width, height) and one temporal; the unity of space and time. Specification of the coordinates precisely locates any physical magnitude whatever. The concept was first suggested by Minkowski and soon after adopted by EINSTEIN. While in classical or Newtonian theory, space-time is separable in an ABSOLUTE way, in Einstein's RELATIVITY theory, this is impossible in an absolute sense but is relative to a choice of a coordinate system.

Spinoza, Benedict (or **Baruch)** (1632–77).—Dutch Jewish philosopher. He argued that nature is a unity, equivalent to a highly abstract and all-pervasive God, and that its facts are necessary and can be derived by a method of rigourous 'proof (as in geometry). Believing that humans were part of nature, Spinoza was a thoroughgoing determinist.

spiritualism—From the Latin *spiritus,* 'breath, life, soul, mind, spirit'. This term has both philosophical and religious meanings. In the first sense, spiritualism is the doctrine that the ultimate reality in the universe is Spirit (*Pneuma, Nous,*

Reason, *Logos*), akin to human spirit, but pervading the entire universe as its ground and rational explanation. It is sometimes used to denote the IDEALISTIC view that only an ABSOLUTE Spirit and FINITE spirits exist, and that the world of sense is a realm of ideas. Religious spiritualism emphasizes the direct influence of the Holy Spirit in the sphere of religion, indicating especially the teaching that God is spirit, and that worship is direct correspondence of Spirit with spirit.

'states of affairs'—See ELEMENTARY PROPOSITION.

statistics—Very generally, this is the branch of mathematics, pure and applied, which deals with collecting, classifying and analysing data. More specifically, in terms of its various breeds in psychology (i.e. descriptive, inferential), statistics refers to sets of procedures developed to describe and analyse particular types of data and enable a researcher to draw various kinds of conclusions on their basis. While in popular usage, it refers to numbers used to represent facts or data.

Stevenson, C(harles) L.—American philosopher, known for his work in ETHICS, and particularly for his views on ethical language. He held that ethical terms have emotive as well as cognitive meaning and have the power to produce affective responses in those who hear and use them. What is involved in ethical discourse, in his view, is the reinforcing or redirecting of attitudes through the affective power of emotive meaning.

stochastic—Meaning 'having to do with PROBABILITY'. A stochastic (as opposed to deterministic) law predicts outcomes as only probable.

structuralism—A method of approach with wide-ranging applications, rather than a distinct philosophy. Its focus is the irreducible structural units that constitute the MORPHOLOGY of a system (i.e., phonology of language, the formal structure of mathematics, the underlying organization of society). The central ideal of structuralism is that cultural phenomena should be understood as manifesting unchanging and universal abstract structures or forms, the meaning of which can be understood only when these forms are revealed.

sub specie aeternitatis—Latin, 'under the view or aspect of eternity'. The phrase used to signify the attempt to see things at once in one thought without any past or future, as a species of eternity—as God might grasp them. The term is commonly associated with SPINOZA.

subjective/subjectivism—Any variety of views that claim that something is subjective—that is, a feature of our minds only, not of the external 'OBJECTIVE' world. Ethical subjectivism, for example, holds that our ethical judgements reflect our own feelings only, not facts about externals.

substance—From the Latin *sub* 'under' and *stare* 'to stand'. Generally, the stuff out of which things are made. The term refers to both the underlying, supporting substratum of something, as well as the individual subject which remains the same through time despite changes in characteristics. It may also mean 'ESSENCE', as that which something really is, despite the way that it appears. In terms of LOGIC, substance is defined according to the notions of subject and predicate; regarded this way *S* is a substance if *S* is a subject of predicates, but cannot be predicated in turn of any other subject. This conception can be traced back to ARISTOTLE and plays an important part in the philosophy of LEIBNIZ.

sufficient reason, principle of—A principle of LEIBNIZ, stating that for every fact there is a reason why it is so and not otherwise. Thus, reason takes the form of an A PRIORI proof founded on the nature of the subject and predicate terms used in stating the fact. Leibniz used the principle freely; to prove, for example, that there could not be two identical atoms (for there would be no reason for one to be in one place and the other somewhere else, rather than vice versa) or that the world did not begin at a moment in time (for there would be no reason for it to have begun at one moment rather than another).

syllogism—A form of deductive argument, in which one PROPOSITION, the conclusion, is inferred from two other propositions, the premisses. For example, 'All Greeks are rational, all Athenians are Greek, therefore all Athenians are rational'. A syllogism has only three terms; the subject term and the predicate term, called 'minor' and 'major', respectively; the other term, which occurs only in the premisses, is called the 'middle' term. The forms of a valid syllogism were first studied systematically by ARISTOTLE, and the theory of the syllogism forms a large part of what is termed 'traditional LOGIC.'

symbols—Philosophers often use symbols to abbreviate logical connections, with letters standing for terms or sentences. For instance, suppose *B* stands for property of being bald. If *f* stands for Fred, *Bf* stands for the sentence 'Fred is bald'. With respect to quantifier LOGIC in which *A,* the universal quantifier, signifies 'all', the formula *(Ax)(Bx)* means 'Everything is bald'; or likewise, in the case of the existential quantifier *E, (Ex)(Bx)* means 'Something is bald'. The equals sign (=) means 'is identical with'.

In sentential logic, there are many symbols that refer to logical connections between sentences, the latter of which are usually abbreviated by capital letters. Here are some examples: the ampersand (&) and the dot (.) are commonly used to stand for 'and'; the horseshoe on its side and the arrow (→) are used for 'if…then'; the wedge or vee (V)stands for the inclusive 'or'; the tilde or curl (~) stands for 'not', where *~P* means 'it is not the case that *P*'; another negation symbol is '-'; the triple bar (≡) or the double arrow (↔) stands for 'if and only if'; etc.

synapse—From the Greek for 'juncture' or 'point of contact'. The functional junction between the axon and the dendrite of two neurons by which nerve impulses flow. The term was coined by SHERRINGTON in 1906.

syntax—The aspect of language which has to do with grammar or logical form. It can tell you whether a sentence is formed correctly but cannot tell you what a correctly formed sentence means, which is the realm of SEMANTICS. The study of syntax, which is part of the general theory of signs, is called syntactics.

synthetic—See ANALYTIC/SYNTHETIC.

systems analysis—Generally and collectively, the processes and operations involved in the designing, implementing and coordinating of the various components of any complex system. More specifically, it is characterized by the use of systematic analytical procedures derived from industrial/organization psychology and assisted by the techniques of computer science to understand the workings of complex organizations, to identify problems

and sources of error and to make recommendations for more efficient and effective structures.

Tarski, Alfred (1902–) Polish-American mathematician and logician. He is the founder of SEMANTICS.

tautology—In ordinary language a tautology says the same thing twice, but in LOGIC, it is used to describe a PROPOSITION which is true by virtue of its form alone. It is sometimes used as a synonym for logical truth, and for some, every definition is tautological. In terms of truth tables a tautology is a statement form, all of whose substitution instances are true. While one might say then that a tautology is necessarily true, some might hold that although this is true, the truth in question is vacuous. WITTGENSTEIN divided meaningful propositions into two classes: those which picture facts, and those which express tautologies.

taxonomy—From the Greek meaning 'laws of arrangement'. Any systematic set of principles for classification and arrangement.

teleology—From the Greek *telos*, 'end', and *logos*, 'discourse' or 'doctrine'. The study of aims, purposes or functions as well as the doctrine that ends, final CAUSES or purposes are to be invoked as principles of explanation. In general, much of traditional philosophy viewed nature and the universe in terms of teleology. The term itself was introduced in the eighteenth century by Christian Wolff.

Theaetetus (c. 414–369 BC)—Theaetetus was a Greek mathematician who joined PLATO in founding the Academy of Athens and whose work was later used by EUCLID. Plato's dialogue *Theaetetus* is devoted to the question of the definition of knowledge.

thermodynamics, first and second law of—The study of the interrelation between heat and other forms of energy. The first law of thermodynamics states simply that heat is a form of energy and that in a closed system the total amount of energy of all kinds remains constant through time. It is therefore the application of the principle of CONSERVATION of energy to include heat energy. The second law deals with the direction in which any chemical or physical process involving energy takes place: it is impossible to construct a continuously operating machine which does mechanical work and which cools a source of heat without producing any other effects. The energy in a closed system tends to decrease with time, while the ENTROPY tends to increase.

transcendental—The sort of thought that attempts to discover the (perhaps universal and necessary) laws of reason, and to deduce consequences from this about how reality must be understood by any mind. KANT used this kind of reasoning—the 'transcendental argument'—to argue in favour of A PRIORI metaphysical truths.

transparency, referential—See OPACITY AND TRANSPARENCY, REFERENTIAL.

truth function—A PROPOSITION is a truth function if, and only if, its truth or falsity is determined by the truth or falsity of its component propositions. For example, to say that 'p and q' is a truth function is to say that, once we can answer the questions (1) 'Is p true? (2) 'Is q true?' we are in a position to answer the question 'Is "p and q" true?'. See FUNCTION.

Turing, Alan Mathison—British mathematician, biologist and philosopher. He

was the key figure, along with VON NEUMANN, in the conception of electronic digital computers and ARTIFICIAL INTELLIGENCE, as well as the concepts of mind that arose alongside of these. He developed the Turing machine, a computer prototype, and queried whether the human mind functioned in an analogous manner or could be simulated by such a machine. He claimed that the success of such a simulation of mind could be gauged, and developed an intelligence test for this purpose. It is known as the 'Turing Test', in which a man's responses to a series of questions is measured against those of a computer (responding by teletype) in an attempt to distinguish which is which. Given that only mental attributes can be questioned in this behaviouristic model, the computer's superior mathematical skills may provide an objection to the test. Turing left the question of whether the machine was conscious open.

types, theory of—A theory devised by RUSSELL to avoid the logical PARADOXES and antinomies which arise from self-reference. Deciding that no class could be a member of itself, he concluded that the class is of a higher type than its members. In the assertion 'Socrates is human', the predicate is thus of a higher type than the subject. In the simple theory of types, the initial type level is that of individuals followed by properties of individuals, properties of properties, etc. While this solved the logical paradoxes, it did not touch certain semantical paradoxes (i.e. the Grelling paradox which distinguished between predicates which have the properties they DENOTE (autological) and those that do not (heterological). The paradoxical question is whether the predicate 'heterological' is autological or heterological). These led Russell, along with WHITEHEAD, to develop the ramified theory of types. Here attention is given not only to the elements of the simple theory but also to the hierarchy of orders—first/second/third…order FUNCTIONS, each function quantifying over a lower type. A 'type fallacy' occurs when this logical hierarchy is disregarded.

universals—These are 'abstract' things—beauty, courage, redness, etc. The problem of universals is, at core, the question of whether these exist in the external world—whether they are real things, or merely the result of our classification (non-existent if there were no minds). Thus, one may be a realist or anti-realist about universals. PLATO'S theory of forms is an early example of REALISM in this sense, while ARISTOTLE and the empiricists are associated with anti-realism. Nominalism is a variety of anti-realism that claims that such abstractions are merely the result of the way we use language.

validity—In common usage an argument is valid if it is permitted by the laws of LOGIC. In fact, the question of the validity of a conclusion is independent of the question of the truth of the premisses, which bears upon the 'soundness' of an argument. In deductive arguments, the conclusion is sound given the truth of the premisses, while in inductive arguments, the truth of the premisses only makes the conclusion more probable. Although in both cases, with the proper logical connections intact, the arguments may be valid. See DEDUCTION/INDUCTION.

verification principle/criterion of verifiability—Advocated by the logical positivists, this criterion states that any statement that is not verifiable is meaningless. For example, since it might be thought impossible to find evidence for or against the statement that 'God loves us', they would deem

this statement not false (or true), but meaningless. Empiricists in general tend to share this position. Some logical positivists used this criterion to argue that statements in METAPHYSICS and ETHICS were meaningless. Further, some of them, including A.J.SAYER, thought that the verification principle provided the definitive answer to questions about meaning. This holds that the meaning of a sentence can only be specified by giving its procedures of verification.

verificationism—In this position, it is argued that scientific work consists of the attempt to substantiate (verify) the correctness of a theory by logical and EMPIRICAL means. It is usually contrasted with falsification, a younger point of view associated with POPPER, that holds that scientific theories cannot be proven to be true but only subjected to attempts at REFUTATION. From this point of view, a scientific theory is accepted, not because it is demonstrably a correct codification of a class of phenomena, but because it has not yet been shown to be false.

Vienna Circle—A group of philosophers who met in Vienna and elsewhere during the 1920 and 1930s. It included SCHLICK, CARNAP, and GÖDEL, among others, and was deeply influenced by WITTGENSTEIN. Reacting against the continental ways of thought that surrounded them, these philosophers produced the groundwork of logical POSITIVISM and proved very influential on future ANALYTIC PHILOSOPHY, especially in Britain and the United States, where many members moved during the rise of Hitler.

virtual particle—A particle which is created for short periods of time where its creation would normally violate the CONSERVATION law of energy and mass. This is due to the uncertainty principle, the consequence of which states that any measurement of a subatomic system must disturb the system under investigation. There is a resulting lack of precision, particularly when the lifetime of a particle is short, and a high degree of uncertainty with respect to its energy.

vitalism—From the Latin *vita*, 'life'. The doctrine that phenomena of life possess a particular character by virtue of which they are distinct from the physico-chemical phenomena of the body and from the mind. Vitalists ascribe the activities of living organisms to the operation of a 'vital force' and are opposed to biological MECHANISTS who assert that living phenomena can be explained exclusively in physico-chemical terms.

volition—The exercise of the will—the power of deciding, desiring, or wanting.

von Neumann, John—Hungarian-born Princeton professor, one of the outstanding mathematicians of this century. He contributed to the development of atomic energy, built one of the first electronic computers, designed many nuclear devices and contributed to game theory—a branch of mathematics concerned with PROBABILITY in its approach to the problem of strategy.

Waisman, Friedrich (1896–1959).—Austrian-born philosopher. Assistant to SCHLICK in Vienna, he moved to Cambridge to study with WITTGENSTEIN where he later taught. Beginning as a logical POSITIVIST committed to mathematical rigour, he came to hold the position that linguistic methods held more promise in dealing with the problems of philosophy.

Watson, John Broadus (1878–1958).—American psychologist, the founder of BEHAVIOURISM. Influenced by SKINNER, and in response to the introspectionist psychology of his day, Watson held that psychology could

only become a productive science, like other NATURAL SCIENCES, if it was OBJECTIVE and dealt with the observable. He launched the movement with his 1913 paper 'Psychology as the Behaviourist Sees It', which was followed by numerous influential articles and books.

wave mechanics—One of the forms of QUANTUM MECHANICS that developed from the theory that a particle can also be regarded as a wave. Wave mechanics is based on the SCHRÖDINGER wave equation describing the wave properties of matter. It relates the energy of a system to a wave function, and in general it is found that a system (such as an atom or molecule) can only have certain allowed wave functions and certain allowed energies. In wave mechanics the QUANTUM conditions arise in a natural way from the basic postulates as solutions of the wave equation.

weak/strong interaction—The interactions between elementary particles at the subatomic level which are, along with gravity and ELECTROMAGNETISM, two of the fundamental FORCES of nature. The weak force produces radioactive decay and the strong force permanently binds quarks (the three known basic particles). Weak interaction, compared with strong, is a trillion times weaker, and when strong interactions take place the weak are unimportant.

Weierstrass, Karl—One of the greatest German mathematicians of the nineteenth century; a teacher of Cantor. He worked in mathematical analysis, in the theory of FUNCTIONS and on ideas that had troubled mathematicians since ancient times: INFINITY and irrational NUMBERS.

Weltanschauung—German, meaning 'world-view, perspective of life, conception of things'.

Weyl, Hermann—German-American scientist and philosopher. Making contributions to both geometry and RELATIVITY theory, his philosophical interest was in philosophy of MATHEMATICS and PHILOSOPHY of science.

Whewell, William (1794–1866). English philosopher. Interested in the methods of the INDUCTIVE sciences, he suggested the importance of 'colligation' in the ordering of scientific data—i.e., finding the conception which allows one to see the facts as connected—and thereby assimilating induction to the hypothetico-deductive method.

Whitehead, Alfred North (1861–1947).—English (Cambridge) philosopher and logician, who developed, with RUSSELL, the first modern systematic symbolic LOGIC. He is also known for his 'process' philosophy in which change, not SUBSTANCE, is fundamental, and in which purpose is a feature of the external world.

Wiener, Norbert (1894–1964).—American mathematician and founder of CYBERNETICS. He joined the faculty of MIT at twenty-five and later, with Arturo Rosenblueth formed an interdisciplinary group in the late 1930s, whose meetings were concerned with scientific method and the unification of science, and from which the concept of cybernetics emerged. The central core of his theories which were inspired by the development of the computer have been developed under the label 'ARTIFICIAL INTELLIGENCE'. This has taken over the concept of man as 'machine-like' and revolutionized the terms in which perception, learning, thinking and language have been conceived of since. He wrote a number of articles with Rosenblueth and Julian Bigelow on

the philosophical aspects of cybernetics, involving VITALISM and Bergsonian time and was concerned with the social dangers of this viewpoint in terms of the need for social evolution to accommodate the rapid technological advances.

Wittgenstein, Ludwig (Josef Johann) (1889–1951).—Austrian-born, he taught at Cambridge and did much of his work in England, where his thought was greatly influential on recent philosophical trends. This is especially true of logical POSITIVISM and ORDINARY LANGUAGE PHILOSOPHY the latter of which he may be seen as the father. His *Tractatus Logico-Philosophicus* (1922) became of immediate consequence to philosophy and drew him permanently into the discipline. He engaged many of the technical problems of contemporary philosophy but is best known for his view of philosophy as therapy, designed to cure puzzles and confusions resulting from misunderstandings of the function of parts of language. He set up a system of linguistic analysis by which any statement must satisfy certain logical conditions before being admitted as a proper philosophical statement. The tools of his system are symbols, which enable a thing to be *shown* in the event that it cannot, because of the limitations of language, be *said*.

Logic

algorithm—See DECISION PROCEDURE.

ampliative argument—An argument or inference whose conclusion goes beyond the information contained in its premisses; an argument in which the premisses fail to provide conclusive evidence for the conclusion. Ampliative arguments include inductive (or non-monotonic) inferences as well as inferences to the best explanation. They may be either acceptable or unacceptable depending upon their strength or weakness.

antinomy—Any paradoxical statement such that its truth leads to a contradiction and the truth of its denial leads to a contradiction; a paradox.

argument—The inference of a conclusion from premisses; a set of sentences (or propositions) supporting or purporting to justify such an inference.

axiomatic system—A logistic system or logical calculus which includes a set of axioms as part of its primitive basis; to be contrasted with a natural deduction system.

belief dynamics—The standard name for theories of belief revision, which are designed in such a way as to model changes in one's belief set which come about both as a result of the acceptance of new beliefs and the revision of old beliefs.

bivalence—The property of a logic in which each well-formed formula has one of exactly two possible truth values: truth and falsehood.

Boolean algebra—A formal system introduced by George Boole which models logical relations algebraically by defining the operations, $\cap$(or $\times$, representing intersection), $\cup$(or +, representing union) and (or -, representing complementation) over a set of elements representing propositions.

bound variable—A variable which falls within the scope of a quantifier; a variable, *x,* to which a quantifier, such as or $\exists$, $\forall$ applies.

calculus—Another name for a logistic system.

Cantor's theorem—The theorem, proved by Georg Cantor in 1891, that the cardinality of the set of all subsets of a given set (the power set of that set) is always greater than that of the set itself. Alternatively, the theorem that the set of real numbers is non-denumerable (or, equivalently, that the cardinality of the set of real numbers is greater than that of the set of natural numbers). Cantor proved both versions of the theorem by means of a diagonal argument.

cardinality—The property of a set associated with the cardinal (or counting) number that measures the number of its members.

category theory—The mathematical study of structures and structure-preserving mappings (or morphisms); the study of mathematical categories, which are defined as sets of objects together with associated sets of morphisms (or arrows) which satisfy certain conditions.

Church's theorem—The metatheorem, proved by Alonzo Church in 1936, that there is no effective decision procedure for determining whether an arbitrary well-formed formula of first-order logic is a theorem. Equivalently, the theorem that the valid formulas of the predicate calculus do not form a general recursive set. Also called the Church-Turing theorem.

Church's thesis—The thesis, suggested by Alonzo Church, that every effectively calculable function (or equivalently, every decidable predicate) is general recursive. Also called the Church-Turing thesis.

classical logic—Any logic for which bivalence holds; alternatively, the propositional and predicate logics originally developed by Gottlob Frege and modified over the years by his successors.

closed sentence—A well-formed formula or sentence in which all variables are bound; to be compared with an open sentence.

combinatory logic—A branch of formal logic which contains functions capable of playing the role of variables in ordinary logic; hence, a branch of logic in which variables are eliminated.

compactness theorem—The metatheorem, proved by Kurt Gödel in 1930, stating that in first-order logic any collection of well-formed formulas of a given language has a model if every finite subset of the collection has a model.

completeness—The property of a logistic system, introduced by E.L.Post, in which for any well-formed formula, either that formula is a theorem of the system or, if added to the system as an axiom, the resulting system would be inconsistent. Alternatively (but not equivalently), the property of a logistic system, introduced by Kurt Gödel, in which all valid well-formed formulas expressible in the system are theorems of the system. In the former sense, the classical propositional calculus but not the pure first-order predicate calculus is complete; in the latter sense, both are complete.

computability—Intuitively, the property of being able to compute a function. A computable function is thus any function for which there exists an effective, finite, mechanical procedure (or algorithm) for calculating a solution. One precise notion of effective computability is that given by the notion of a Turing machine; another is that of a general recursive function.

conclusion—That which is inferred from or purportedly justified by the premisses of an argument.

confirmation theory—The theory of the degree to which evidence supports (or

confirms) a given hypothesis; the theory of rational degrees of confidence that a cognitive agent should have in favour of a hypothesis, given some body of evidence.

connective—A symbol used to join one or more prepositional constants or forms. The result is a new constant or form. Standard connectives include symbols representing negation (~), conjunction (&), (inclusive) disjunction ($\vee$), material implication ($\rightarrow$), and material equivalence ($\leftrightarrow$).

consistency—The property of a set of statements or propositions or of a logistic system in which no contradiction (the joint assertion of a proposition and its denial) can be derived. Alternatively (but not equivalently), the property, introduced by Alfred Tarski, of a logistic system that not every well-formed formula is a theorem. Alternatively (but not equivalently), the property, introduced by E.L.Post, of a logistic system that no well-formed formula consisting of only a prepositional variable is a theorem. Alternatively (but not equivalently), the property of a logistic system of having a model. This last is called the semantic definition of consistency.

constructivism—The view that satisfactory proofs (and definitions) refer only to entities which can be successfully constructed or discovered. Thus, constructive proofs, unlike indirect proofs or proofs by *reductio ad absurdum,* are ones which allow us to find examples, or to find algorithms for finding examples, of each set of objects which purportedly have some given property, *P*.

continuum hypothesis—The hypothesis, suggested by Georg Cantor, that there is no set with cardinality greater than that of the natural numbers but less than that of the power set of the natural numbers. When generalized, the hypothesis states that there is no set with cardinality greater than a given infinite set but less than that of the power set of that set.

Cook's theorem—The theorem, proved by Stephen Cook in 1971, that the problem of satisfiability is at least as difficult to solve as is any NP-complete problem.

counterfactual—A conditional sentence in which the antecedent is false.

decision problem—The problem of finding an effective, finite, mechanical decision procedure (or algorithm) for arriving at an answer to a given question. Typically, the most common decision problem with regard to logistic systems is the problem of determining whether an arbitrary, well-formed formula of the system is a theorem of the system. A positive solution to a decision problem is a proof that an effective decision procedure exists. A negative solution to a decision problem is a proof that an effective decision procedure does not exist. An example of a positive solution is the proof that truth tables provide an effective decision procedure for the propositional calculus. An example of a negative solution is Church's theorem for the predicate calculus.

decision procedure—A procedure for coming to a decision with regard to a given question. The procedure is said to be effective, or to be an algorithm, provided that it results in the correct answer following a finite number of mechanical steps.

decision theory—The theory of selection under various conditions of risk and uncertainty; the theory of rational choice, given that each option has associated with it an expected probability distribution of outcomes, gains and

losses. Decision theory, together with game theory, is often called the theory of practical rationality.

deducibility—The relation, symbolized $\vdash$ and contrasted with entailment, that holds between a statement (or proposition), *C*, and a set of statements (or propositions), *P*, provided that *C* is provable from *P*.

deduction—An argument or inference in which the conclusion, *C*, is provable from the premisses, *P*. Alternatively, but less commonly, an argument or inference in which the premisses provide conclusive evidence for the conclusion; a valid argument or entailment.

deduction theorem—The metatheorem that states that, in a given logistic system, if $s_1, s_2, \ldots, s_n \vdash s_{n+1}$, then $s_1, s_2, \ldots, s_{n-1} \vdash s_n \rightarrow s_{n+1}$.

deductive logic—The formal study of deductions or of arguments or inferences in which the premisses provide conclusive evidence for the conclusion.

default logic—A form of nonmonotonic logic which permits the acceptance or rejection of certain types of default propositions simply in the absence of information to the contrary.

denumerable—A denumerable set is any set whose cardinality is equal to that of the natural numbers, the smallest of infinite sets. A non-denumerable set is one whose cardinality is greater than that of the natural numbers; to be contrasted with an enumerable set.

deontic logic—Any logic emphasizing inferential relations and entailments which result from deontic properties of sentences, such as obligation and permission, and obtained from a classical logic, such as the propositional calculus or the predicate calculus, by the addition of axioms and rules of inference governing operators such as *O* and *P* in '*Op*' ('it ought to be the case that *p*') and '*Pp*' ('it is permissible that *p*').

detachment—The rule of inference (also called *modus ponens*) that, given well-formed formulas of the form *p* and $p \rightarrow q$, one can infer a well-formed formula of the form *q*.

diagonal argument—An argument introduced by Georg Cantor to show that certain sets have distinct cardinalities; a method or procedure for constructing objects on the basis of other objects in such a way that the new objects are guaranteed to differ from the old. When generalized, this method becomes one of the most powerful tools in metamathematics.

entailment—The relation, symbolized $\models$ and contrasted with deducibility, that holds between a statement (or proposition), *C*, and a set of statements (or propositions), *P*, provided that *C* follows from *P*. Alternatively, an argument or inference in which the conclusion, *C*, follows from the premisses, *P*, or in which the premisses provide conclusive evidence for the conclusion. In this sense, entailment is often identified with validity, the property of being logically impossible that the premisses should be true while at the same time the conclusion be false. Others suggest it be identified with a stronger relation in order to avoid the paradoxes of strict implication.

enumerable—An enumerable set is any set whose cardinality is equal to that of some (finite) natural number or to the cardinality of the set of natural numbers as a whole. A synonym of 'countable'; to be contrasted with a denumerable set.

epistemic logic—Any logic emphasizing inferential relations and entailments which result from epistemic properties of sentences and obtained from a classical logic, such as the propositional calculus or the predicate calculus, by the addition of axioms and/or rules of inference governing operators such as *K* and *B* in *'Kp'* ('it is known that *p*') and *'Bp'* ('it is believed that *p*').

erotetic logic—Any logic emphasizing inferential relations and entailments pertaining to questions and answers.

existential quantifier—A symbol such as '∃'which is used in combination wit a variable to represent the notion 'there exists'. For example, under the appropriate interpretation *'(∃x=x)'* could be used to symbolize 'There exists an *x*, such that *x* is identical with itself' or, more informally, 'Something is identical with itself'.

fallacy—An argument which although neither valid nor inductively strong is nevertheless persuasive; any error in reasoning.

finitary method (finitism)—A method of metamathematical research adhered to by David Hilbert and his followers which emphasizes the use of only finite, well-defined and constructible objects. Like constructivism, finitism holds that we cannot assert the existence of a mathematical object unless we can also indicate how to go about constructing it. Unlike constructivism, it also requires that one should never refer to completed infinite totalities.

finitism—See FINITARY METHOD.

first-order language—A language whose quantifiers and functions are allowed to range over only individuals. In contrast, the quantifiers and functions of higher-order languages may range over properties and functions as well as individuals.

first-order logic—The logic of valid inferences carried out in first-order languages; also called first-order predicate (or functional) logic. See predicate logic.

formal language—A collection of well-formed formulas together with an interpretation.

formal logic—The study of arguments whose validity or inductive strength depends exclusively or primarily upon the form or structure, rather than the material content, of their component statements or propositions.

formal system—Another name for a logical calculus.

formalism—A programme of research into the foundations of mathematics initiated by David Hilbert and using the finitary method.

formation rule—Any rule of a logistic system governing which combinations of (primitive) symbols constitute well-formed formulas.

formula—Any sequence of primitive symbols; sometimes used as a synonym for well-formed formula.

free logic—Any logic in which it is not assumed that names successfully refer; a logic without existence assumptions.

free variable—A variable which is not bound by a quantifier.

function—A many-one correspondence. Also called a map or mapping, a function is a relation which associates members, *x*, of one set, *X*, with some unique member, *y*, of another set, *Y*. We write *f(x)=y*, or *f*: *X*→*Y*, and name *X* the domain and *Y* the range of the function *f*.

functional logic—Another name for predicate logic.

future contingents, problem of—The problem, first raised by Aristotle but popularized by Jan Łukasiewicz, of whether contingent statements

concerning the future have truth-values prior to the time to which they refer.

fuzzy logic—An extension of logic which attempts to deal with imprecise information such as information conveyed through vague predicates or information associated with so-called fuzzy sets, sets in which membership is a matter of degree.

game theory—The mathematical theory of selection by two or more agents (or players) when the outcome is a function, not just of one's own choice or strategy, but the choices or strategies of other agents as well. Game theory, together with decision theory, is often called the theory of practical rationality.

general recursive function—A type of recursive function definable in terms of primitive recursive functions together with minimization.

Gentzen's consistency proof—The 1936 proof by Gerhard Gentzen, using transfinite induction up to the ordinal ε_0, that classical pure number theory is consistent.

Gödel numbering—The systematic assignment of natural numbers to the components and formulas of a formal system in such a way that, by studying the properties and relations of the correlated numbers, one is able to infer information about the syntax of the underlying formal system.

Gödel's completeness theorem—The metatheorem, proved by Kurt Gödel in 1930, that every valid well-formed formula of (pure) first-order predicate logic is a theorem of that system.

Gödel's incompleteness theorems—The two 1931 theorems of Kurt Gödel relating to the incompleteness of systems of elementary number theory. The first theorem states that any ω-consistent system adequate to express elementary number theory is incomplete in the sense that there is a valid well-formed formula of the system that is not provable within the system. (In 1936 this theorem was extended by J.B.Rosser to apply to any consistent system.) The second theorem states that no consistent system adequate to express elementary number theory can contain a proof of a sentence which states the system's own consistency.

halting problem—The problem of discovering an effective procedure for determining whether a computational device (such as a Turing machine) will ever halt, given arbitrary input.

higher-order language—A language whose quantifiers and functions are allowed to range over properties and functions as well as individuals.

higher-order logic—The logic of valid inferences carried out in higher-order languages.

imperative logic—Any logic emphasizing inferential relations and entailments which result from imperatives.

induction—An ampliative argument from empirical premisses to an empirical conclusion. For example, in induction by simple enumeration, given observed objects *a*, *b* and *c* of some kind, *G*, if it turns out that *a*, *b*, and *c* also all have property *F*, then one might conclude that all future observed *G*s will be *F*, or perhaps that all *G*s are *F*. Inductions may be either acceptable or unacceptable depending upon their inductive strength or weakness.

inductive logic—The formal study of inductions, of ampliative arguments or inferences from empirical premisses to empirical conclusions, in which the premisses fail to provide conclusive evidence for the conclusion.

inductive strength—The degree of support a non-conclusive argument's premisses give to its conclusion. In cases where the conclusion is likely to be true given the premisses, the argument is said to be inductively strong. In cases where the conclusion is not likely to be true given the premisses, the argument is said to be inductively weak.

inference rule—Also known as a transformation rule, any justification of a well-formed formula within a logistic system of the form, 'Given well-formed formulas of the form $s_1,\ldots s_n$, infer a well-formed formula of the form s_m'.

informal logic—The study of arguments whose validity or inductive strength depends exclusively or primarily upon the material content, rather than the form or structure, of their component statements or propositions.

interpretation—The meanings of, or alternatively a method of assigning meanings to, a set of well-formed formulas or to a formal system. Thus, given a set, *S*, of well-formed formulas, an interpretation consists of a non-empty set (or domain), together with a function which (i) assigns to each individual constant found in members of *S* an element of the domain; (ii) assigns to each *n*-place predicate found in members of *S* an *n*-place relation of the domain; (iii) assigns to each *n*-place function-name found in members of *S* a function whose arguments are *n*-tuples of elements of the domain and whose values are also elements of the domain; and (iv) assigns to each sentence letter a truth value. Logical constants, such as those representing truth functions and quantifiers, are assigned standard meanings using rules (such as truth tables) which specify how well-formed formulas containing them are to be evaluated.

interrogative logic—Another name for erotetic logic.

intuitionism—A program of research into the foundations of mathematics initiated by L.E.J.Brouwer; a species of constructivism.

intuitionistic logic—A logic which formalizes the 'intuitionistic' view that the subject matter of mathematics consists of mental constructions made by mathematicians. Classical proofs (such as those which rely upon indirect proof or *reductio ad absurdum* arguments) are therefore not admissible since they do not contain the appropriate constructions. In intuitionistic logic, the sentence '$p\ \neg p$' is not a theorem and the inferences from $\neg\neg p$ to p and from$\neg\ (\forall x)Fx$ to $(\exists x)\ \neg Fx$ are not allowed.

lambda calculus A logic governing the manipulation of functions, which gains its name from the notation used to name functions. Terms such as '*f*(*x*)' or the 'successor of *y*' are used to refer to objects obtained from *x* or *y* by the appropriate functions. To refer to the functions themselves, Alonzo Church introduced the notation which yields, respectively, and '(λx) ($f(x)$)' and '(λx) (successor of y)'.

logic—The study of correct inference. Alternatively, the science of validity and of inductive strength, and of all formal structures and informal properties relating to correct inference. The term is also used as a synonym for 'logical calculus'.

logical calculus—Any systematic treatment of logical inference in which a primitive basis—consisting of a formal language, including a vocabulary of primitive elements and a set of formation rules (or grammar), and a logic, including a (possibly empty) set of axioms and a set of transformation rules—is explicitly stated in the system's metalanguage. Also called a formal system or a

logistic system. The two most important classical logical calculi are the prepositional (or sentential) calculus and the predicate (or functional) calculus.

logical constant—A symbol used to represent topic-neutral expressions which are relevant to a sentence's logical form. Standard logical constants include symbols used to represent truth-functions such as negation (~), conjunction (&), (inclusive) disjunction ($\vee$), material implication ($\rightarrow$), and material equivalence ($\leftrightarrow$), the universal and existential quantifiers ($\forall$ and $\exists$), the identity relation (=), and scope indicators (such as '(' and ')').

logical form—The structure of a sentence or argument relevant to that sentence or argument's logical relations. The logical form of an expression is typically obtained by making explicit the expression's logical constants and by substituting free variables for its non-logical constants. Logical form is contrasted with the material content (or subject matter) of the non-logical constants for which the free variables are substituted.

logical paradox—A paradox not involving semantic notions such as reference or truth; to be contrasted with a semantic paradox.

logicism—The doctrine, variously advanced by Gottlob Frege, Bertrand Russell, Alfred North Whitehead and others, that (some or all branches of) mathematics can reduced to logic. Specifically, it is the view that the concepts of (some or all branches of) mathematics can be defined in terms of purely logical concepts and that the theorems of (these same branches of) mathematics can in turn be deduced from purely logical axioms.

logistic system—Another name for a logical calculus.

Löwenheim-Skolem theorems—Any of a series of metatheorems relating to Leopold Löwenheim's 1915 theorem, that if there is an interpretation in which a well-formed formula is true, then there is an interpretation in which the formula is true and whose domain is enumerable, and to Thoralf Skolem's 1920 extension of this theorem.

many-valued logic—Any logic, such as that developed by Jan Łukasiewicz, which countenances more than the two possible classical truth values: truth and falsity.

material content—The subject matter of a sentence or argument, in contrast to the sentence or argument's logical form.

material implication—The truth function, normally written $p \rightarrow q$ or $p \supset q$, which is false if and only if p (its antecedent) is true but q (its consequent) is false.

material implication, paradoxes of—Any of a number of unintuitive (but, strictly speaking, non-contradictory) results to the effect that whenever the antecedent is false or the consequent is true in a material implication, the resulting implication will be true, regardless of its content; to be contrasted with the paradoxes of strict implication.

mathematical logic—Another name for formal logic, particularly for those branches of formal logic which rely upon mathematical tools and concepts, or which are suitable for expressing mathematical theories.

mereology—A logic emphasizing inferential relations and entailments which result from the relationship of whole and part.

metalanguage—A language used to talk about a (usually separate) language called an object language.

metalogic—A logical theory whose subject matter is a particular logical calculus or logistic system; the study of logical calculi from the point of view of a separate metalanguage.

metamathematics—The study of logistic systems used to model mathematical theories and in which formulas of the theory (such as axioms, theorems and proofs) are themselves assumed to be mathematical objects. Sometimes the term is restricted to proof theory, or to proof theory using only finitary methods.

metatheorem—A theorem proved in a metalanguage; a theorem of metalogic or metamathematics.

metatheory—A theory in a metalanguage concerning a separate theory or logistic system.

modal logic—Any logic emphasizing inferential relations and entailments which result from alethic modalities such as necessity, possibility and impossibility, and obtained from a classical logic, such as the prepositional calculus or the predicate calculus, by the addition of axioms and rules of inference governing operators such as $\Box$ and $\Diamond$ in '$\Box p$' ('it is necessary that p') and '$\Diamond p$' ('it is possible that p').

model—An interpretation of a set of sentences (or of a logistic system) under which all sentences (or theorems) turn out to be true.

model theory—The study of interpretations of formal systems; the study of relations of (semantic) consequence between sentences (and sets of sentences) within an interpreted logistic system.

modus ponens—Another name for the rule of detachment.

multi-valued logic—A synonym for many-valued logic.

natural deduction system—A logistic system or logical calculus which avoids the use of axioms, relying instead upon a sufficiently powerful set of rules of inference; to be contrasted with an axiomatic system.

non-monotonic logic—The formal study of ampliative reasoning; a type of logic which is sensitive to changing evidence and so allows for the revision or overturning of previously proved theorems.

NP-complete—An abbreviation for 'non-deterministic, polynomial-time-complete', the property of the most difficult class of problems for which there is no polynomial time solution but whose solutions, if they exist, are checkable within polynomial time.

object language—A language referred to by a metalanguage. Alternatively, a language used to talk about (usually non-linguistic) objects.

ω completeness—The property of a formal system in which, if it has as theorems that a given property, *P,* holds of all individual natural numbers, then it also has as a theorem that *P* holds of all numbers.

ω consistency—The property of a formal system in which, if it has as theorems that a given property, *P,* holds of all individual natural numbers, then it fails to have as a theorem that *P* fails to hold of all numbers.

open sentence—A formula or sentence in which not all variables are bound. Alternatively, a predicate; to be contrasted with a closed sentence.

paraconsistent logic—Any logical calculus which is inconsistent in the sense that a contradiction (the joint assertion of a proposition and its denial) can be derived; but consistent in the sense (introduced by Alfred Tarski) that not every well-formed formula is a theorem.

paradox—The existence of apparently conclusive arguments in favour of contradictory propositions. Equivalently, the existence of apparently conclusive arguments both in favour of accepting, and in favour of rejecting, the same proposition. The distinction between logical paradoxes (such as Russell's paradox) and semantic paradoxes (such as the liar paradox) is due to Guiseppe Peano and Frank Ramsey.

Peano's postulates—A set of postulates introduced by Richard Dedekind and popularized by Guiseppe Peano which defines the set of natural numbers as a series of successors to the number zero.

pleonotetic logic—A synonym for plurality logic.

plurality logic—Any logic emphasizing inferential relations and entailments pertaining to relations of quantity and using plurality quantifiers such as most and few.

plurative logic—A synonym for plurality logic.

Polish notation—A logical notation devised by Jan Łukasiewicz which avoids the need for scope indicators (such as parentheses) in formal languages by using an unambiguous system of ordering. Thus, letting N represent negation, K represent conjunction, A represent disjunction (or alternation), R represent exclusive disjunction, C represent material implication, E represent material equivalence, L represent necessity, and M represent possibility, sentences such as $\sim (p \rightarrow (p \ \& \ q))$ and $\Box(p \rightarrow p)$ can be represented as $NCpKpq$ and $LCpp$, respectively.

predicate—An expression representing a condition or relation and which, when connected with one or more referring terms, forms a sentence. The resulting sentence is taken to be true when the predicate expresses a condition or relation that is satisfied by the referred-to entities, and false otherwise.

predicate logic—A logical calculus which analyses the relations between individuals and predicates within propositions (or statements), in additional to the truth-functional relations between propositions (or statements) that are analyzed within propositional logic. Each such system is based upon a set of individual and predicate (or functional) constants, individual (and sometime predicate) variables, and quantifiers (such as $\exists$ and $\forall$) which range over (some of) these variables, as well as the standard constants and connectives of the propositional calculus.

preference logic—Any logic emphasizing inferential relations and entailments which result from preferences.

premiss—One of a set of sentences (or propositions) which support or purport to justify a conclusion.

primitive basis—A set of primitive symbols, formation rules, axioms and inference rules (transformation rules) used to characterize a logicist system.

primitive recursive function—A type of recursive function definable by recursion and substitution from a set of fundamental functions including the constant functions, the projection (or identity) functions, and the successor function.

primitive symbols—A set of undefined symbols, including constants, variables, connectives and operators, used as the basic vocabulary of a language.

probability—A measure of the acceptability of a statement or proposition; a measure of likelihood.

probability theory—A mathematical theory of the acceptability of a statement or proposition, or of likelihood, axiomatized by Andrej Kolmogorov in 1933 as a non-negative real-value additive set function with a maximum value of unity.

proof—Any finite list of well-formed formulas in a logistic system, each of which is either an axiom of the system or results from the previous members of the list together with the inference rules of the system. The final formula in the list is said to be a theorem of the system.

proof theory—The study of the syntax of formal systems; the study of relations of (syntactic) deducibility between formulas (and sets of formulas) within a logistic system. Sometimes the term is restricted to the study of formal systems using only the finitary methods suggested by David Hilbert.

propositional function—A notion introduced by Gottlob Frege as a formal equivalent to that of a property; a function having as its domain a set of referring terms (such as individual constants) and as its range a set of propositions or truth values.

propositional logic—A logical calculus which analyses the truth-functional relations between propositions (or statements). Each such system is based upon a set of propositional (or sentential) constants and connectives (or operators) which are combined in various ways to produce sentences of greater complexity. Standard connectives include those representing negation ($\sim$), conjunction (&), (inclusive) disjunction ($\vee$), material implication ($\rightarrow$), and material equivalence ($\leftrightarrow$).

quantification theory—Another name for predicate logic.

quantifier—An operator, such as the existential or universal quantifiers, $\exists$ and $\forall$, first introduced by Gottlob Frege to indicate what was traditionally called the quantity of a proposition, namely, whether it was universal or particular.

quantum logic—A logic in which the law of distributivity fails; any logic designed to take account of the unusual entailment relations between propositions in theories of contemporary quantum physics.

recursion theory—The theory of recursive functions.

recursive function—Any of a set of functions which are said to be either primitive recursive or general recursive, and which are constructed from a set of fundamental functions by a series of fixed procedures. Specifically, a function is primitive recursive if it is definable by recursion and substitution from a set of fundamental functions including the constant functions, the projection (or identity) functions, and the successor function. A function is general recursive (or simply recursive) if it is definable in terms of the primitive recursive functions together with minimization.

recursive procedure—A procedure which is applied iteratively in such a way that each non-initial application is applied to the result of the previous application.

recursive set—Any set such that both it and its complement can be enumerated by recursive functions.

relevance logic—Any logic emphasizing inferential relations and entailments which involve connections of relevance between premisses and conclusions, rather than simple classical derivability conditions; a type of paraconsistent

logic involving an implication relation stronger than strict implication and designed to avoid the paradoxes of implication and of strict implication.

Russell's paradox—The most famous of the logical or set-theoretical paradoxes. The paradox comes from considering the set of all sets which are not members of themselves, since this set appears to be a member of itself if and only if it is not a member of itself. Discovered by Russell in 1901, the paradox prompted much work in logic and set theory during the early part of this century.

satisfiability—The property of an open sentence such that, given some non-empty domain of individuals, there is a possible assignment of individuals to the formula's free variables such that the resulting formula is true. Alternatively, the property of any set of sentences which can be given an interpretation, relative to a domain, such that all of the sentences turn out to be true. Thus, the problem of satisfiability is the problem, given an arbitrary set of sentences, of determining whether the set is satisfiable.

scope (of a quantifier)—The part of an expression to which a quantifier, such as $\exists$ or $\forall$, applies. Thus, a variable, x, falls within the scope of a quantifier provided that the quantifier applies to it.

second-order language—The most elementary of higher-order languages, in which quantifiers and functions are allowed to range over properties and functions of individuals, as well as individuals.

second-order logic—The logic of valid inferences carried out in second-order languages; the most elementary of higher-order logics.

semantic paradox—A paradox involving semantic notions such as reference or truth; to be contrasted with a logical paradox.

semantics—The meanings of the symbols of a formal system and the study of their properties and relations, including the theory of reference (or denotation) and the theory of meaning (or connotation).

sentential logic—Another name for prepositional logic.

set—Intuitively, any collection of well-defined, distinct objects. The objects which determine a set are called the elements or members of the set. The symbol $\in$ is regularly used to denote the relation of membership or elementhood. Thus '$a \in A$' is read 'a is an element (or member) of A' or 'a belongs to A'. Two sets are identical if and only if they contain exactly the same elements.

set theory—The systematic study of sets, their properties and relations. Motivated both by Georg Cantor's discovery of the set-theoretic hierarchy and by the paradoxes of naive set theory which accompanied it, the first standard axiomatization, Z, of the theory was provided by Ernst Zermelo in 1908.

Skolem-Löwenheim theorems—Another name for the Löwenheim-Skolem theorems.

Skolem's paradox—The unintuitive (but ultimately non-contradictory) result that systems for which Cantor's theorem is provable, and hence which must contain non-denumerable sets, nevertheless must be satisfiable, because of the Löwenheim-Skolem theorems, in an enumerably infinite domain.

soundness—The property of a logistic system in which all theorems of the system are valid well-formed formulas.

strict implication—A relation between two formulas, p and q, such that it is not possible that both p and $\sim q$. In such cases p is said to strictly imply q.

strict implication, paradoxes of—The unintuitive (but, strictly speaking, non-contradictory) results that a necessary proposition is strictly implied by any proposition and that an impossible proposition strictly implies all propositions, regardless of their content; to be contrasted with the paradoxes of material implication.

substitution—The rule of inference that, given one well-formed formula, one can infer a second well-formed formula from the first by uniformly replacing every variable of a given kind by some distinct variable.

successor—For a given member of an ordering, the member of the ordering which next follows.

symbolic logic—Another name for formal logic.

syntax—The symbols of a formal system and the study of their properties and relations, including the distinction between well-formed and ill-formed formulas.

tautology—Any compound sentence or formula of the prepositional calculus which, because of its logical structure, is true regardless of the truth values of its constituent sentences.

temporal logic—Any logic which is sensitive to the tense of sentences and to the changing truth values of sentences over time; a logic emphasizing inferential relations and entailments which result from properties of tensed sentences.

tense logic—Another name for temporal logic.

theorem—Any well-formed formula of a logistic system which is provable within the system.

theory—Any set of well-formed formulas. Alternatively, a set of well-formed formulas closed under logical entailment.

transformation rule—Another name for an inference rule.

truth function—Any function whose arguments and values are truth values.

truth table—A matrix which lists the truth value of a compound proposition for all possible assignments of truth values to its constituent propositions.

truth value—In classical logic, the two abstract entities which serve as the reference of true and false sentences, respectively, truth and falsehood. In many-valued logics, any values which play similar roles.

Turing-computable—The property of any function capable of being computed by a Turing machine. The set of Turing-computable functions turns out to be identical to the set of general recursive functions. See Church's thesis.

Turing machine—A theoretical machine introduced by Alan Turing in order to make precise the idea of (effective) computability. Intuitively, the machine can be thought of as a computer which manipulates information contained on a linear tape (which is infinite in both directions) according to a series of instructions. More formally, the machine can be thought of as a set of ordered quintuples, q_i, s_i, s_j, I_i, q_j, where q_i is the current state of the machine, s_i is the symbol currently being read on the tape, s_j, is the symbol with which the machine replaces S_i, I_i is an instruction to move the tape one unit to the right, to the left, or to remain where it is, and q_j is the machine's next state.

types, theory of—A theory of the correct structure of an ideal language, and introduced by Bertrand Russell as a means of blocking paradoxes such as the paradox of the set of all sets which are not members of themselves (Russell's paradox). Russell's idea was that by ordering the objects (and eventually

predicates) of a language or theory into a hierarchy (beginning with individuals at the lowest level, sets of individuals at the next lowest level, etc.), one could avoid reference being made to sets such as the set of all sets, since there would be no level at which such a set appeared.

universal quantifier—A symbol such as ∀ which is used in combination with a variable to represent the notion 'for all'. For example, under the appropriate interpretation '(∀x) *(x=x)*' could be used to symbolize 'For all *x*, *x* is identical with itself or, more informally, 'Everything is identical with itself'.

validity—The property of any inference such that the joint assertion of its premisses and denial of its conclusion results in a contradiction. Alternatively, the property of any well-formed formula which is true under all interpretations; that is, given any non-empty domain, every possible assignment of values to its free variables results in a true sentence.

well-formed formula—Any formula of a logistic system which is grammatically correct; a sentence.

Loeb, J. 343, 347–50, 363
logarithm 403
logic 168, 184, 196, 225, 245, 403–4, 436, 394; algebra of 10; ampliative arguments 37; applied 37; application of 179; Aristotelian 32, 129–30; Boolean 130; classical 32–5, 80–1, 431; combinatory 34, 431; completeness of 25; consequence relation 33; constants in 23; constructive 25; counterfactual 36; deductive 433; default 37, 433; definitions for arithmetical terms 14; deontic 433; development of 50, 55; epistemic 35, 434; erotetic 434; expansion of 32–8; first-order 24–6, 32, 434; first system of 126; formal 36, 434; foundations of 16, 157; free 34, 434; functional 434; fuzzy 36, 435; higher-order 435; imperative 36, 43 5; impoverished state of 69; inductive 436; informal 9, 19, 36, 436; interrogative 436;

intuitionistic 94, 436; laws of 66, 173–4, 184–5; many-valued 23, 34, 437; mathematical 292, 301, 405, 437; modal 23, 407, 438; modern 124, 126–32; multi-valued 438; mathematization of 12; modal extension to 35; multigrade connective in 36; non-monotonic 37, 438; not psychological 171; of existence 93–4; of knowledge 93–4; of terms 128; paraconsistent 32–3, 439; philosophy of 9–49; plurality, pleonotetic or plurative 36, 439; predicate 35–6, 129, 439; preference 36, 439; principles of 19; propositional 24, 28, 3 5–6, 440; quantum 34, 440; relation between premisses and conclusion 9; relevance 32–3, 441; second-order/higher-order 24, 36, 441; sentential 441; status of physical properties 222; study of formal systems 9; systems 24; symbolic 105, 442; tense/temporal 36, 442; unsolved problems 16–7
logical atomism 404
logical fiction 331
logical form 96, 101, 164, 437
logical operators 80, 128–9, 411
logical paradox 437
logical picture 133
logical positivism 88, 107, 183, 186, 193–210, 301, 404, 415
logical relation 173–4
logicism 54, 56–70, 73, 88–93, 124, 404, 437; epistemological 90; metaphysical 93; methodological 93; scope of 67; second-generation 92
logico-grammatical distinction 352
Lorentz transformation 219–20, 226, 404
Lotze, R.H. 124, 339–41, 343–4, 404
Löwenheim, L. 21
Löwenheim-Skolem theorems 25, 437
Lucas, J.R. 226
Lucretius 214, 404–5
Lukasiewicz, J. 23, 34, 129
Lundberg, G.A. 267

McCulloch, W. 292, 311
McGuiness, B.F. 157
Mach, E. 223, 231–2, 405
machine 335, 338, 341, 348, 351, 354
MacKay, D.M. 311
Maclaurin's paradox 225
macro-level regularity 270
macrostate 296–7
Maddy, P. 102
magic 239, 241, 243–5
Maimonides 244, 405
manipulability 222
mass 217, 230–2, 405
material content 437
material implication 437; paradoxes of 33, 437
materialism 311–12, 315, 321, 326, 332, 405; eliminative 352; physical or descriptive 325; reductionist 325; scientific 325, 327–9, 340; vital 325
mathematical practice 143
mathematics 1, 196, 225; and/of physics 215, 226; as a game 81, 96; as convention 96; auxilliary 215; classical 79, 85; complete formalization of 27; definition of mathematical sequence 14; elementary arithmetical parts 99; formalist 50; foundational issues in 16; ideal 81, 84, 6; immune to empirical revision; induction and verification 100–1; intuitionist 50, 94–5; judgements synthetic 52, 55; knowledge is logical 90; logicism 27; logicist 50; logicization of 12, 55, 65, 69; merged with natural science 99; needed for cognitive processing 93; new axioms in 100; philosophy of 9–10, 53, 56, 88, 124, 405; place of logical reasoning in 91; pure 55, 68; science of most general truths 66–7; refutation of intuition in 69; representational 216; reverse 85, 87; rooted in rational agents 92;

spatial or quasi-spatial intuition in foundation of 76; transforms logic 9; trend to empiricism 107; unsolved problems 16–17
matrix theory 226, 405–6
matter 231, 322, 324
Maxwell's demon 299
Maxwell, J.C. 219, 269–70, 351, 406
meaning 2, 145, 168, 195–202, 310, 360; is use 94; of life 184
mechanics 219–20, 226, 232, 330, 334; laws of 219; Newtonian 176–7, 185, 225–6, 230, 409–10; of unconscious behaviour 342; physics is 229; quantum 216, 226–7, 418; wave 226, 429
mechanism 237, 293, 295, 300, 303, 315–66, 406; cerebral 366; control 330; error-correcting 303; heliotropic 343; homeostatic 330, 349, 351; information-processing 332; neural 341; neurophysiological 353; post-computational 322, 335, 353–4
mechanist quadrumvirate 325, 347
mechanist-vitalist debate 315–66; demise of 329
Meinong, A.M. 167–9, 406
memory 326; associative 347–8
mental construct 320, 355
mental states 169, 345–6, 359
mereology 36, 438
Mersenne, M. 317, 406
Merton, R.K. 244, 271
metabolism 300
metalanguage 19, 185–6, 406, 438
metalogic 22, 24, 438
metamathematics 438; arithmetization of 83; predicates 26
metaphysics 9, 186, 193, 199–200, 206–8, 230, 235, 237, 243–4, 257–8, 268, 322–3, 328, 347, 407
metatheorems 25, 438
metatheory 438
methodology 235–7, 283, 326–7, 407
Mettrie, J.O.de la 317, 327, 402
Michelson, A.A. 219, 221
micro-level unpredictability 270, 297
microstate 296
microstructure 296–7
Mill, J.S. 88, 195, 340, 407
mind 51, 70, 94, 169, 171, 196, 317, 320, 322, 332–3, 338, 343, 346, 355, 364–5, 407
mind's eye 317
mind/body problem 323–5, 329, 333, 350, 353, 407
Minkowsky manifold 220
Minkowsky, H. 220
Minsky, M. 294
mistakes 146–7
model 225, 239, 266–7, 274, 330, 354, 364, 438; in logic 225; quasi-causal 267; of reality 353; of the world 223–4
model making 364
model theory 22, 364, 438
modus ponens 14, 184, 407, 438
modus tollens 407
Moleschott, J. 325, 327, 408
momentum 217, 221, 408
monism 408
monkey trial 243
Monro, A. 335
Moore, G.E. 178, 205, 408
morality 209–10, 357, 408
Morgan, A.de 10–11, 55, 389
Morgenstern, O. 292
Morley, E.W. 219, 221
morphology 305, 408
Morse-Kelly class theory 32
Moses 244
movement *see* action
Müller, J.P. 322, 408
multiple regression 408
mysticism 184, 186, 207, 408

name 126, 157–9, 165, 170, 179, 181–3, 185, 196; proper 137, 404; simple 179
natural selection 305–7, 309
nature 239, 330; laws of 176–9, 218–21, 324–5, 387
necessity 161
neo-Cartesianism 341
neo-pragmatism 224

nervous system 293, 298, 303, 308, 330, 332, 336, 337, 339, 350; autonomic 340; efferent/afferent 390
Neumann, J.von 21, 292–3, 428
Neurath, O. 195, 203–4, 409
neurological imprinting 340
neurology 303
neurophysiology 292, 301, 326, 347, 353
neuropsychology 354, 409
neutral monism 312, 409
Newell, A. 336
Newton, I. 230, 232, 258, 316, 324–5, 337, 409
Newtonian matter theory 216
niche 306, 308
nihilism 410
nomological 410
nonsense 169–70, 172, 185, 360
normal curve 270
normal distribution 280
normative 410
NP-complete 438
number 104, 134–5, 137–8, 175, 410; as sets 137; complex 12; concept 60–2, 138; definition of 132–3; finitary number theory 100, 104; ontological characteristics 103; reference of, 143; science of 104; zero 133–4, 144; *see also* arithmetic
number theory, elementary 26, 391; predicates 26
Nyquist, H. 293, 297

object 79, 103, 131, 135, 141, 158–60, 165, 167, 169–70, 178–83, 185, 196, 356; constitution of 143; logical 60–1, 64; of direct acquaintance 178; properties/features of 180–2; quasi-concrete 104
Objective 167, 169–70
objective 410
objectivity 77
observation 279, 361, 364; statements 203
observer 318–19
Occam's/Ockham's razor 410
Ogden, C.K. 157
Olbers, H.W.M. 53
ontological commitment 168
ontology/ontological 169–70, 185, 221–3, 226, 269, 357, 410
opacity and transparency, referential 410–11
operationism 202, 411
operator *see* logical operator
option, possible, preferred, rule-ordered 278
order from disorder principle 269–70, 411
ordinary language philosophy 411
organism 293, 295, 300–1, 305, 307–10, 325, 343, 350, 353; genetic structure of 304–5
organizational theory 302, 412
orientalism 412
oscillator 412
outcome 276–8
Ozanam, J. 236
ω-completeness 438
ω-consistency 26, 438
ω-particle 228

Papert, S. 294
paradigm 412; revolution 354
paradox 412, 439; distinction between set-theoretic and semantic 20–1
paramorph 223
parapsychology 247, 249, 412
pari passu 412
Parsons, C. 98–9, 104
Pascal, B. 302, 412
Passmore, J. 193
pattern formation 309
Patzig, G. 129–30
Pavlov, I.P. 349–50, 412–13

Routledge History of Philosophy
Volume X

Philosophy of Meaning, Knowledge and Value in the 20th Century

Routledge History of Philosophy Volume X

Volume X of the *Routledge History of Philosophy* presents a historical survey of the central topics in twentieth-century Anglo-American philosophy. It chronicles what has been termed the 'linguistic turn' in analytic philosophy and traces the influence the study of language has had on the main problems of philosophy. Each chapter contains an extensive bibliography of the major writings in the field.

In keeping with the importance of the linguistic turn, the introduction and the first two essays in the book deal with the philosophy of language. A subsequent series of essays concentrates on the central areas of metaphysics, ethics and epistemology. The book also covers the traditional, related topics of aesthetics, political philosophy and the philosophy of religion. Then there are essays on domains that have only become prominent in this century, namely, applied ethics, feminist philosophy and the philosophy of law. One chapter is devoted to the later Wittgenstein.

The book's authors have contributed to the on-going discussions they cover, some of them prominently. All the essays present their large and complex topics in a clear and well organized way. The reader will find a helpful Chronology of major events in philosophy, logic and science in the twentieth century and an extensive Glossary of technical terms.

John V.Canfield lives in Toronto. He has taught philosophy at Cornell University and the University of Toronto, and is the author of *Wittgenstein: Language and World* (1981) and *The Looking-Glass Self* (1990). He is currently working on a book of essays on Wittgenstein.

Routledge History of Philosophy

General Editors—G.H.R.Parkinson and S.G.Shanker

The *Routledge History of Philosophy* provides a chronological survey of the history of Western philosophy, from its beginnings in the sixth century BC to the present time. It discusses all major philosophical developments in depth. Most space is allocated to those individuals who, by common consent, are regarded as great philosophers. But lesser figures have not been neglected, and together the ten volumes of the *History* include basic and critical information about every significant philosopher of the past and present. These philosophers are clearly situated within the cultural and, in particular, the scientific context of their time.

The *History* is intended not only for the specialist, but also for the student and the general reader. Each chapter is by an acknowledged authority in the field. The chapters are written in an accessible style and a glossary of technical terms is provided in each volume.

I *From the Beginning to Plato* C.C.W.Taylor (published 1997)

II *Hellenistic and Early Medieval Philosophy* David Furley

III *Medieval Philosophy* John Marenbon

IV *The Renaissance and C17 Rationalism* G.H.R.Parkinson (published 1993)

General editors' preface

The history of philosophy, as its name implies, represents a union of two very different disciplines, each of which imposes severe constraints upon the other. As an exercise in the history of ideas, it demands that one acquire a 'period eye': a thorough understanding of how the thinkers whom it studies viewed the problems which they sought to resolve, the conceptual frameworks in which they addressed these issues, their assumptions and objectives, their blind spots and miscues. But as an exercise in philosophy, we are engaged in much more than simply a descriptive task. There is a crucial critical aspect to our efforts: we are looking for the cogency as much as the development of an argument, for its bearing on questions which continue to preoccupy us as much as the impact which it may have had on the evolution of philosophical thought.

The history of philosophy thus requires a delicate balancing act from its practitioners. We read these writings with the full benefit of historical hindsight. We can see why the minor contributions remained minor and where the grand systems broke down: sometimes as a result of internal pressures, sometimes because of a failure to overcome an insuperable obstacle, sometimes because of a dramatic technological or sociological change, and, quite often, because of nothing more than a shift in intellectual fashion or interests. Yet, because of our continuing philosophical concern with many of the same problems, we cannot afford to look dispassionately at these works. We want to know what lessons are to be learned from the inconsequential or the glorious failures; many times we want to plead for a contemporary relevance in the overlooked theory or to consider whether the 'glorious failure' was indeed such or simply ahead of its time: perhaps even ahead of its author.

We find ourselves, therefore, much like the mythical 'radical translator' who has so fascinated modern philosophers, trying to understand an author's ideas in their and their culture's eyes, and, at the same time, in our own. It can be a formidable task. Many times we fail in the historical undertaking because our philosophical interests are so strong, or lose sight of the latter because we are so enthralled by the former. But the nature of philosophy is such that we are compelled to master both techniques. For learning about the history of philosophy is not just a challenging and engaging pastime: it is an essential element in learning about the nature of philosophy—in grasping how philosophy is intimately connected with and yet distinct from both history and science.

The *Routledge History of Philosophy* provides a chronological survey of the history of western philosophy, from its beginnings up to the present time. Its aim is to discuss all major philosophical developments in depth, and, with this in mind, most space has been allocated to those individuals who, by common consent, are regarded as great philosophers. But lesser figures have not been neglected, and it is hoped that the reader will be able to find, in the ten volumes of the *History,* at least basic information about any significant philosopher of the past or present.

Philosophical thinking does not occur in isolation from other human activities, and this *History* tries to situate philosophers within the cultural, and in particular the scientific, context of their time. Some philosophers, indeed, would regard philosophy as merely ancillary to the natural sciences; but even if this view is rejected, it can hardly be denied that the sciences have had a great influence on what is now regarded as philosophy, and it is important that this influence should be set forth clearly. Not that these volumes are intended to provide a mere record of the factors that influenced philosophical thinking; philosophy is a discipline with its own standards of argument, and the presentation of the ways in which these arguments have developed is the main concern of this *History*.

In speaking of 'what is now regarded as philosophy', we may have given the impression that there now exists a single view of what philosophy is. This is certainly not the case; on the contrary, there exist serious differences of opinion, among those who call themselves philosophers, about the nature of their subject. These differences are reflected in the existence at the present time of two main schools of thought, usually described as 'analytic' and 'continental' philosophy. It is not our intention, as general editors of this *History,* to take sides in this dispute. Our attitude is one of tolerance, and our hope is that these volumes will contribute to an understanding of how philosophers have reached the positions which they now occupy.

One final comment. Philosophy has long been a highly technical subject, with its own specialized vocabulary. This *History* is intended not only for the specialist but also for the general reader. To this end, we have tried to ensure that each chapter is written in an accessible style; and since technicalities are unavoidable, a glossary of technical terms is provided in each volume. In this way these volumes will, we hope, contribute to a wider understanding of a subject which is of the highest importance to all thinking people.

G.H.R.Parkinson
S.G.Shanker

Notes on contributors

Robert L.Arrington is Professor of Philosophy at Georgia State University in Atlanta, Georgia. He is the author of *Rationalism, Realism, and Relativism* (1989) and the co-editor of *Wittgenstein's Philosophical Investigations* (1991) and the forthcoming *Wittgenstein and Quine*. Currently he is writing a history of ethics and editing *A Companion to the Philosophers*.

John V.Canfield is Professor Emeritus at the University of Toronto. He is the author of *Wittgenstein: Language and World* (1981), *The Looking-Glass Self* (1990), and papers on Wittgenstein and the philosophy of language. He is the editor (with Frank Donnell) of *The Theory of Knowledge* (1964), *Purpose in Nature* (1966), *The Philosophy of Wittgenstein* (in fifteen volumes, 1986) and (with Stuart Shanker) *Wittgenstein's Intentions* (1993).

Nino B.Cocchiarella is Professor of Philosophy at Indiana University. He is the author of *Logical Investigations of Predication Theory and the Problem of Universals* (1986), *Logical Studies in Early Analytic Philosophy* (1987), and numerous articles including 'Conceptualism, Realism, and Intensional Logic' and 'Conceptual Realism versus Quine on Classes and Higher-Order Logic'.

William James DeAngelis is Associate Professor of Philosophy at Northeastern University in Boston, Massachusetts, where he has been the recipient of a Presidential Excellence-in-Teaching Award. His publications have been in the area of metaphysics and Wittgenstein studies; currently he is preparing a book on the philosophy of religion.

George Dickie lives in Chicago; he is the author of *Art and the Aesthetic* (1974), *The Art Circle* (1984), *Evaluating Art* (1988) and *The Century of Taste* (1996).

Marilyn Frye teaches Philosophy and Women's Studies at Michigan State University. Her essays are collected in *The Politics of Reality* (1983) and *Willful Virgin* (1992).

Sarah Lucia Hoagland is Professor of Philosophy and Women's Studies at Northeastern Illinois University, in Chicago. She is author of *Lesbian Ethics* (1988), and co-editor of *For Lesbians Only: A Separatist Anthology* (1992).

Bernard Linsky is in the Department of Philosophy of the University of Alberta. He has written articles on philosophical logic, modal metaphysics and Bertrand Russell, interests similar to those of his father, Leonard Linsky.

A.P.Martinich teaches philosophy at the University of Texas at Austin; he is the editor of *The Philosophy of Language* (1985) and the author of papers in that field.

Paul K.Moser is Professor of Philosophy at Loyola University of Chicago. He is the author of *Empirical Justification* (1985), *Knowledge and Evidence* (1989) and *Philosophy after Objectivity* (1993), editor of *Empirical Knowledge* (1986), *A Priori Knowledge* (1987), *Rationality in Action* (1990) and *Human*

Knowledge (2nd edn, 1995), among other collections, and author of a number of articles on epistemology. He is the general editor of the new book series, *Routledge Contemporary Introductions to Philosophy*.

Calvin G.Normore is Professor of Philosophy at Erindale College, University of Toronto. He has published and lectured widely in a variety of areas including medieval philosophy, social and political philosophy, history of logic and decision theory.

Justin Oakley is Lecturer at the Centre for Human Bioethics, Monash University, Australia. He is the author of *Morality and the Emotions* (1992), and has published articles on ethical theory, medical ethics and bioethics. He is currently completing a manuscript with Dean Cocking on virtue ethics in medicine.

Arthur Ripstein teaches philosophy at Erindale College, University of Toronto. He has published widely in the fields of legal and political philosophy and is currently at work on a book on responsibility and luck.

Michael Stingl teaches philosophy at the University of Lethbridge. His research interests include ethical naturalism and various applied issues in biomedical ethics. He is currently editing a book on reforming the Canadian health system.

Edward Wierenga is Professor of Religion and chair of the Department of Religion and Classics at the University of Rochester (NY). He is the author of *The Nature of God* (1989) and numerous articles.

Chronology

Introduction

John V.Canfield

This volume presents a chronological survey of some central topics in twentieth-century philosophy in the English-speaking world. A companion volume focuses on logic, the philosophy of science and related subjects, while another covers recent continental philosophy.[1] By way of a broad introduction to the essays printed here I shall discuss some characteristic features of modern Anglo-American philosophy.

Above all what distinguishes that way of thought is its passion for clarity. The attitude is reflected, for example, in Wittgenstein's remark that, 'People who have no need for transparency in their argumentation are lost to philosophy.'[2] The urge towards clarity is itself a concomitant of the so-called 'linguistic turn' that is the distinctive feature of twentieth-century Anglo-American philosophy. The phrase 'the linguistic turn' refers to a change from a relatively small concern with questions about language to a major one. It's not just that by and large, in this century, writers spend more time investigating the nature of language and allied problems, though that is true: compare, for example, the percentage of text devoted to such issues in Locke's *Essay* and Wittgenstein's *Philosophical Investigations*. It is rather that in various ways issues about language become the fundamental ones. This can be seen for instance in A.J.Ayer's famous book *Language, Truth, and Logic* where the first order of business is to establish the bounds of sensible language, and where pretty much everything else is said to follow from that alleged achievement.

The involvement with language that I am discussing has several distinct foci, and in what follows I shall consider three of them: *logical form, meaninglessness* and its opposite, *meaning*. A sentence as it appears in some natural language like English may not show forth its correct, underlying structure or form, which must rather be uncovered by the philosopher. Thus a statement's surface form—the form it appears to have—is contrasted with its real or *logical* form. The notion of logical form presupposes our having some way of characterizing those hidden or disguised structures. Historically, and as the term itself indicates, early characterizations of logical form employed the vocabulary of modern logic.

Modern logic was developed by Frege and Russell in the context of an attempt to prove the consistency of mathematics by deriving it from logic. To carry out that programme logic itself had first to be revamped. Here Frege made the essential contribution, by introducing the so called 'quantifiers'.[3] In a radical departure from classical or Aristotelian subject-predicate logic he originated the notion of the universal quantifier 'for all x' and the existential quantifier 'there exists an x'. Given those tools he was able to analyse sentences like 'All men are mortal' and 'Socrates is a man' in a more perspicuous way than the old logic could. It is the apparatus and vocabulary of the new logic that first inspired the search in recent philosophy for logical form.

Bertrand Russell's original and highly influential essay of 1905, 'On Denoting', applied ideas like those just mentioned from modern or mathematical logic to the discovery of logical form. Thus Russell's paper marks a key point in the development of Anglo-American philosophy. The particular issue he addresses has

a technical or arcane air, but understanding it is essential to grasping the use subsequent thinkers made of his ideas, and thus necessary for understanding one central aspect of the philosophy discussed in this volume. (For a fuller discussion, see Professor Martinich's essay in this volume, 'Philosophy of language'.)[4] In Russell's well-known example the sentence, 'The present King of France is bald' appears to be of subject-predicate form with 'The present King of France' filling the subject role. On this reading the sentence has the same form as 'Jones is bald'. It *seems* that in each case something picked out by a singular referring expression (one that, like a proper name, picks out one individual) is said to have a certain property. This reading of the sentence causes trouble. The present King of France, like the unicorn in my garden, does not exist, so there is nothing for Russell's sentence to be about. If it is about nothing it must, apparently, be senseless. Yet we understand it. In response to that puzzle, Russell argued that when we correctly analyse the statement, and thus get to the level of its true or logical form, the phrase 'the present King of France' disappears; the sentence's true form is quite different from its apparent one. In the analysis we find only variables such as *'x'* and *'y',* the logical functions 'for all *x*' and 'there exists an *x* such that', and the *predicates* 'is presently King of France' and 'is bald'. Rendered in English, the statement's logical form is: there is at least one thing that is presently King of France, and any thing that is presently King of France is identical to that one thing, and that thing is bald. Since in fact there is nothing that is presently King of France, the statement in question is merely false, not senseless.

The idea of a hidden logical form underlying the propositions of ordinary or natural language was taken by Wittgenstein as a basic presupposition of his enormously influential book the *Tractatus Logico-Philosophicus* (1921). Wittgenstein thought that it was not necessary for the logician to describe the exact logical form of propositions; it was enough if he could come to know in general terms what that form is. Every proposition, he believed, could be analysed into a collection of elementary propositions linked by the so-called truth-functions *and, not, or* and *if…then*. Elementary propositions are those that cannot be analysed further. In the *Tractatus,* they consist solely of names of simple objects. The 'molecular propositions' that express ordinary language statements are formed by joining elementary propositions by means of the truth-functions. All meaningful propositions have the logical form just described; all would-be propositions lacking it are meaningless. A sentence can be meaningless even though we think it has sense; it is a question of its logical form.

Wittgenstein's quest to uncover the true logical form of the sentences of our language was motivated by more than the wish to demarcate clearly the line between what could and could not be said. In addition, he believed that the structure of reality mirrors the structure of propositions, so that to discover the form of language is to establish *a priori* the form of the world. For example, to take one clearly momentous would-be result, Wittgenstein holds that first-person sentences like 'I believe that *P*' (where *P* is some proposition) have the form '*"P"* says that *P*'. The alleged subject—the believer *qua* Cartesian ego or mind—disappears in the analysis; reality thus contains no such entity as the self. By focusing on language the 'linguistic turn' in no way trivialized philosophy.

Many contemporary philosophers operate with some variant of the idea of logical form. Donald Davidson, for example, utilizes something like the classical Russellian idea of logical form. As Bernard Linsky points out in his essay on metaphysics in chapter 4, the aim of Davidson's work on the nature of events is to formulate ordinary event-statements in 'first-order logic'. As in the *Tractatus* the underlying motivation is to discover the true form of reality.

Other philosophers continue to seek a correct analysis, in the sense of finding the underlying form of philosophically significant propositions, but without assuming that this form is to be captured in the vocabulary of logic. *Such* concern with the hidden form of statements is found, for example, in Roderick Chisholm's treatment of the metaphysical question of the nature of appearances—those mysterious mental

objects postulated by Descartes and so many subsequent thinkers, and which give rise to numerous puzzling questions.[5] Chisholm claims that a correct understanding of sentences about how things appear shows them to have an adverbial rather than a substantive core. If something that may or may not actually be red looks red to Jones, we might say that Jones is aware of a red appearance. Instead of this latter way of speaking, Chisholm holds that in truth what we should say is 'Jones is appeared to redly.' A surface grammatical substantive is to be replaced by a depth grammatical adverb. So in contradistinction to the message of surface grammar, reality does not contain such things as *red appearances*. It contains only agents, like Jones, who perceive in a certain way, described by the use of adverbs. Thus the old question about the nature of appearances (aka 'sense data') is rejected; the question, rather, is said to arise from a faulty understanding of the form of appearance-statements. While the search for logical form is one of the family-resemblance elements distinctive of Anglo-American philosophy, that inquiry itself can take on various guises, as just illustrated.

Another of the points at issue in the 'linguistic turn' is that of *meaninglessness*. (The topic is discussed in several places in the following essays, including William James DeAngelis's chapter on metaphysics.) The notion that certain seemingly important philosophical claims may be in fact hidden nonsense is an old one. There are versions of it in Hume and Kant, for example. In our century the early Wittgenstein's ideas were especially influential in bringing the idea of meaninglessness to centre stage. Every meaningful proposition, he held, has the form 'This is how things are,' where the proposition makes some empirical claim about the world; if it makes no empirical claim it is meaningless. This conception was developed by the *logical positivists,* whose empiricist criterion of meaning attempted to give a precise formulation to Wittgenstein's idea. For the positivists a meaningful sentence must either make some in principle verifiable statement about the world or else be 'tautological' like the statements of mathematics and logic. All other statements, despite their appearance of making sense, are to be judged nonsense. The following statement, for example, would fail their test: 'All the measuring rods in the universe, and anything capable of serving as such, are shrinking by one-half every second.' Since no evidence could possibly either confirm or deny the claim, and since it is no empty tautology like 'Either it is raining or it is not raining' the statement is judged senseless. Similarly for Russell's example: 'The universe came into existence five minutes ago, complete with all our memories, the fossil record, all signs of aging and decay pointing to a distant past, and so on.' These are merely illustrative instances; the positivists' test of meaningfulness had a more significant target. It was meant to exclude from the realm of the sensible such would-be questions as 'Does God exist?'—along with most of the other questions of traditional metaphysics. As Carnap wrote in 1950: 'Influenced by ideas of Ludwig Wittgenstein, the [Vienna] Circle [where logical positivism originated] rejected both the thesis of the reality of the external world and the thesis of its irreality as pseudo-statements; the same was the case for both the thesis of the reality of universals…and the nominalistic thesis that they are not real.'[6]

While the verificationism associated with the positivists is not popular nowadays, and while therefore there is little corresponding talk of metaphysics as meaningless, nevertheless the influence of the positivist tradition lives on. For the positivists, when the hopelessly muddled questions or 'pseudo-statements' of traditional metaphysics are seen for what they are, the only job left philosophy is as an adjunct to science. Above all, then, the positivists were in the vanguard of the tradition some have called scientism, according to which philosophy becomes either subservient to or an ancillary of science, and in particular of the hard sciences, especially physics. A prediction made by Morton White at the midpoint of the century has certainly proven to hold, at least for a wide range of contemporary philosophers:

> Analytic philosophy will no longer be sharply separated from science, and an unbridgeable chasm will no longer divide those who see meanings or essences and those who collect facts.[7]

The idea of merging philosophy with science is certainly alive and well today, for instance in Carnap's pupil Quine. Again, writers like Jerry Fodor and Paul and Patricia Churchland, in such debates as that over so-called folk psychology, see themselves as doing science, though at a foundational or conceptually oriented level.[8] Correspondingly some social scientists employ ideas drawn from those philosophers in an attempt to establish hypotheses by observation—for instance they deploy field data in an attempt to say whether monkeys have a crude version of 'folk psychology' as Fodor and other philosophers understand that idea.

While concern with *meaninglessness* has certainly abated in our half of the century, concern with its opposite, *meaning,* still rides high. Concern with meaning has two facets: the theoretical problem of saying what meaningfulness or meaning consists in, and the applied problem of uncovering the meaning of particular philosophically important words or claims. Concerning the theoretical issue, perhaps the most; influential contribution to it was Frege's distinction between *sense* and *reference*. The theoretical aspect of the problem of meaning is discussed by Professor Martinich; here I turn instead briefly to what I called the applied problem—finding the meaning of individual words.

Russell in his introduction to the *Tractates* claimed that Wittgenstein was concerned with an ideal language rather than with language as it is. Frege, in his ground-breaking discussions, was explicitly concerned with developing a language that would serve the purposes of science, and thus was not concerned with language as it actually exists, in mufti. But that was not Wittgenstein's position. Wittgenstein thought that every ordinary-language statement was perfectly all right as it stands (*Tractatus,* 5.5563); it's just that we do not know its hidden form —something we can only come to through analysis, by finding the 'one and only complete analysis of the proposition' (*Tractatus,* 3.25).

Concern with an improved or ideal language and concern with the natural, unimproved language of ordinary life each take on various forms in the development of Anglo-American philosophy, and sometimes the one strain is dominant, sometimes the other. In the 1950s and 1960s 'ordinary-language philosophy' held a prominent place. Its paradigmatic practitioners were Gilbert Ryle and John Austin, though in fact the two are very different in their approaches. Wittgenstein's later philosophy is also, but I think wrongly, seen as belonging to the tradition of 'ordinary-language philosophy' associated with Austin and Ryle. Philosophers working roughly in that tradition sought to uncover the ordinary meaning of philosophically relevant words, for example the word 'ought' conspicuous in debates in ethics, or the word 'can' featured in discussions about freedom of the will. Would-be accounts of the meaning of such words—analyses of them —were tested against ordinary usage. In particular a would-be analysis could be refuted by 'counter-examples'—cases where 'what we would ordinarily say' is in conflict with a given account of what we would say. The guiding idea behind the enterprise of analysis was this: In talking about 'ought' (for instance) we use a word from our common vocabulary. Its meaning is already fixed by ordinary usage. To really know what we are saying when we use the word we must study it; we must analyse it. In attempting to provide such analyses philosophers would put forward alleged necessary and sufficient conditions for the application of a given word. Thus a much discussed analysis of 'knowledge' was as follows: Jones knows *p if and only if* (1) Jones believes *p,* (2) Jones has reliable evidence for *p,* and (3) *p* is true.

Alternative versions of analysis developed on the 'ideal-language' side. It was argued that one should not seek simply to uncover the ordinary meaning of philosophically significant words, for they might well be vague and perhaps even contradictory. Rather, as some held, one should seek 'rational reconstructions' of such terms, keeping their core meanings but sharpening up their boundaries and eliminating any inconsistencies. This move away from a standard form of 'ordinary-language philosophy' was to prove superior in survival value.

In subsequent decades 'analysis' took various forms. One was the search for so-called 'criteria'. For instance, the question 'What is the criterion that governs our ascriptions of personal identity?' was (and still is) widely discussed. Here the term 'criterion' was drawn from Wittgenstein's later philosophy, but the procedure actually employed in discovering 'criteria' seems markedly similar to the old (non-Wittgensteinian) one of searching for an analysis, in the sense of searching for necessary and sufficient meaning-conditions. One surface difference is that now instead of appealing to what we would say, an appeal is made to our intuitions concerning various puzzle cases. What does our intuition tell us, for example, about Lockean examples of alleged change of bodies? If someone wakes up not only in the cobbler's bed, but occupying the body of the cobbler while retaining all the Prince's memories, desires, expectations, and so on, is the creature in the lowly cot the Prince?

One's answer reflects one's 'intuition'. Such intuitions fill roughly the role of perceptions in grounding scientific theory. Correspondingly, in recent times the search for analyses has been largely replaced by attempts to provide *theories,* so called. For instance philosophers may seek a theory of personal identity, or of proper names. In the latter instance the theory is supposed to tell us what relationship holds between a given name and its bearer. One such theory—Russell's — associates a set of definite descriptions with a given name, and holds that the object that meets or satisfies the definite descriptions is the thing the name names. On another theory the relationship between name and bearer is *causal*. These theories resemble analyses of the rational reconstruction type, in that one is allowed more leeway with regard to possible 'counter-examples'. In this connection, the point is sometimes made that old-style ordinary-language philosophy is conservative; it requires that the concepts we use in philosophy be restricted to those that exist in natural language. And, it is said, where would science be if it were so restricted? Like scientists, philosophers should be allowed their technical terms and their corresponding theories. Here the philosopher seeks to ally him or herself with science, the most prestigious twentieth-century institution.

One form of 'theory' was influenced by Chomsky's work in linguistics. Starting in the 1960s Jerrold J.Katz and Jerry Fodor attempted to extend Chomsky's ideas by postulating an empirical study of meaning, or 'semantics'.[9] This was a supposed supplement to Chomsky's theory of syntax. Katz argued that one could apply the empirical results of such a study to the direct solution of philosophical problems, offering a kind of scientific ordinary-language philosophy. The solutions would come about when we learned, through empirical work, the full-blown meaning in natural language of the terms involved in a given philosophical debate. On the other hand, meta-theoretical terms like 'analytic' could be given rational reconstructions in terms of the postulated new science of meaning. Katz's methodological conjectures were one precursor of later undertakings by others to provide solutions to philosophical problems through scientific inquiry.

We have been examining some of the distinctive roots and paradigms of Anglo-American philosophy in this century. Modern logic first stimulated an interest in, and provided tools for, the study of language, but that study took on a life of its own, and an increased significance as the century progressed. The resulting Anglo-American tradition of inquiry was marked most significantly by the influence, in various ways, of Frege's account of propositions, Russell's paradigm of analysis, and Wittgenstein's *Tractates,* an influence which is still felt strongly even in a time when it is 'theories' of various sorts that preoccupy analytic philosophers. As indicated, I believe the most valuable legacy of that triumvirate is a hard-headed search for clarity with regard to the basic problems of philosophy.

In keeping with the obvious historic importance of the linguistic turn the present collection begins with two essays on language. Subsequent articles on metaphysics, ethics and epistemology—those traditionally central areas of philosophy—document the significance of deliberations about language for twentieth-century Anglo-American philosophy, as does the chapter on the later philosophy of Wittgenstein. The remaining six chapters, on various *philosophies of,* vary in the importance they attach to the linguistic turn.

Perhaps counter-intuitively, the essays on aesthetics and the philosophy of religion focus most on issues about language. At the other pole, philosophers' rejection of traditional analytic methodologies is evident in the essay on feminist philosophy and in the later sections of the chapter on political philosophy. The chapters on the philosophy of law and applied ethics fall between those two extremes.

As always, change is in the air. After a period of relative stability there are signs that major transformations are coming; the intellectual fashion seems due for a radical re-make. That outlying area the philosophy of education provides one indicator: it has almost wholly abandoned an until recently dominant analytic focus in favour of various post-modern and continental ideas. In mainstream philosophy the same sort of alteration is signalled by a relatively new concern on some people's part with the writings of Martin Heidegger—the same thinker that philosophers of my generation knew only as a target of Carnap's anti-metaphysical animus and consequently as the infamous author of the claim that 'The Nothing itself nothings.' On the other hand, there is certainly still a lot of vigorous life left in the son of Anglo-American philosophy reported upon in these pages, which explicitly or implicitly pursues conceptual clarification. Pessimistic readers, foreseeing the sorts of changes indicated just above, and unwilling to forsake the quest for clarity, may find comfort in the fact that mainland Europe seems to be moving in the opposite direction, back towards the concerns and methods of analytic philosophy, in a belated recognition of the significance of Frege, Russell, Wittgenstein, Schlick, Carnap and other ground-breaking figures.

One of the most difficult of intellectual tasks is to survey a large and complex body of thought and present it in a clear, well-organized way. Each of my co-authors faced such a task, and I thank them for what they have completed so successfully.[10]

A final note: in recent philosophy science has, by and large, taken over the role once played by religion. Science is widely considered the ultimate source of truth, and as something the philosopher had best emulate or join. Given the importance of science for philosophy, I have reproduced here, from Stuart Shanker's volume IX in this series, and with his permission, a chronological table listing the major events in our century's development of science and technology.

NOTES

1 The presupposed geographic and linguistic contrast between Anglo-American and continental philosophy is a bit misleading. Several of those who formed the Anglo-American viewpoint were German or Austrian nationals, including the godfather of analytic philosophy, Gottlob Frege, the immensely influential figures Schlick and Carnap, and the immortal Wittgenstein. Frege's influence worked in part through Bertrand Russell and other Anglo-American figures, Wittgenstein's intellectual life had Cambridge, England, as its centre, and migrations out of Nazi Germany resulted in the impact of the logical positivism associated with Schlick and Carnap being most felt in Britain and North America. Again, the French writer Pierre Duhem deeply influenced that key contemporary American metaphysician Willard van Orman Quine. More significantly, neither the English-speaking nor the continental side is homogeneous; many markedly different ways of philosophizing fall under the one label and many still different ones under the other. Nevertheless the schools do diverge significantly.

2 'Philosophy', ed. Heikki Nyman, trans. C.G.Luckhardt and M.A.E.Aue, in *Ludwig Wittgenstein, Philosophical Occasions 1912–1951,* eds James Klagge and Alfred Nordmann (Indianapolis: Hackett, 1993): 183.

3 It is less well known that the American philosopher Charles Sanders Peirce independently made the same invention.

4 In fact the following account does not square perfectly with the actual text of 'On Denoting'; I give rather what has come to be commonly accepted in philosophy as the main lesson of that essay.

CHAPTER 1
Philosophy of language

A.P.Martinich

LANGUAGE AND ITS USES

Most philosophers of language[1] in the twentieth century distinguish between three aspects of language or its use: syntax, semantics and pragmatics.[2]

Syntax is the study of the ways that words and other elements of language can be strung together to form grammatical units, without taking the meaning of the sentence into consideration at all. The sentences, 'Smith are happy' and 'Smith happy is', are both syntactically incorrect. The sentence 'Smith is happy' is syntactically correct as is the sentence 'Green ideas sleep furiously'. The latter sentence may appear to be defective. If it is, it is because a literal meaning cannot be assigned to it. But meaning is a concept that belongs not to syntax but to semantics, which will be discussed shortly.

Human languages consist of an infinite number of sentences. It is easy to see how a new sentence can be built out of a simpler sentence indefinitely:

This is the house that Jack built.
This is the malt that lay in the house that Jack built.
This is the mouse that ate the malt that lay in the house that Jack built.
This is the cat that chased….

Since human beings are limited in intelligence and they learn a language in a finite amount of time, its syntax must be finite. That is, a grammar for a human language must consist of a finite number of words and a finite number of rules from which the sentences are formed. Because most of the important work on syntax has been done by linguists and formal logicians, nothing further will be said here about this topic. (See chapter 2.)

Semantics is the study of the meaning of words and sentences. Meaning has generally been thought of as a relationship between words and the world. Reference and truth are the two principal concepts used in semantics. During the 1920s and 1930s, many philosophers thought that it was impossible to have a science of semantics, because semantics tries to use words to do something that words cannot do. Words can be used to talk only about things; but semantics is the attempt to talk about the relationship between words and things. That relationship cannot itself be a thing, because if it were, then one could ask what connects that relationship to those other things. If the answer is that there is some other relationship that connects them, then if that additional relationship itself is a thing, one can ask the very same question over again; and this would lead to an infinite regress. The problem that seems to undermine the possibility of semantics can be

put in global terms. Language represents the world, but semantics exceeds the representational ability of language by trying to represent the *relationship* between language and the world.

In the 1930s, Alfred Tarski showed philosophers a way that semantics could be done without violating the expressive limits of language. Semantics then dominated the philosophy of language until the end of the 1950s. (See pp. 12–18 and 18–21.)

The study of pragmatics began to acquire importance in the early 1950s and flourished until the early 1980s. (See pp. 21–6.) Pragmatics is the study of how language is used. Speakers can use language to make statements, promises and bets; to ask questions; to issue commands; to express condolences; and so on. Pragmatics focuses on the interaction between speakers and hearers. The major idea that guides research in this area is that speaking is intentional behaviour and governed by rules. (For an alternative understanding of pragmatics, see chapter 2.)

Semantical studies were reinvigorated in the early 1970s and continue today. (See pp. 26–31.) But at the same time, some of the assumptions that made possible the distinction among syntax, semantics and pragmatics were challenged by other philosophers, and a very different conception of language has begun to emerge. (See pp. 31–5.)

THE NAMING THEORY OF MEANING

What originally motivated philosophers in the twentieth century to study the nature of language as intensively as they have is their traditional concern with the nature of truth and reality. An ordinary sentence or statement is true, it seems, when it corresponds with the facts. Truth then would seem to reside in language, and the nature of truth can be fully understood only when the nature of language is. Concerning reality, many philosophers at the beginning of the century were frustrated by the apparent failure of metaphysicians to discover the nature of reality by studying it directly. Thus arose the idea that perhaps reality could be studied indirectly by studying language. Since language reflects reality, discovering the structure of language would reveal the structure of reality. Here then were two reasons for philosophers to study language: to understand the nature of truth and to understand the structure of reality.

One aspect of language, namely referring, received a disproportionate amount of attention, because of its connection with truth. If truth requires correspondence between elements of language and entities in the world, and if language reflects the world, then language must attach to the world at certain points. The way that language attaches to the world is *reference*. Reference is usually thought of as a feature of proper names or subject expressions that denote individual objects, because individual objects existing in space and time seem to be the basic constituents of the world. Such considerations inspired the simplest and perhaps the most resilient semantic theory, the naming theory of meaning.

According to this theory, the meaning of a word is the object it names or refers to. Ludwig Wittgenstein presented a stark version of the theory in *Tractatus Logico-Philosophicus* (first published in German in 1921 and in English translation in 1922). He wrote, ‘A name means *[bedeutet]* an object. The object is its meaning’ (Proposition 3.203). Although names are the basic building blocks of sentences, names alone do not express a thought. Names are concatenated or strung together to form prepositional signs (sentences). Since Wittgenstein defines a fact as an existing configuration of objects (2–2.011), prepositional signs are themselves facts. Imagine a very simple language that expresses thoughts by the arrangement of its names. Then, the sentence

Adam Beth Carol

means that Beth is between Adam and Carol.

European languages are one-dimensional in the sense that the only significant aspect of the arrangement of a word in a sentence is its linear order. But nothing prevents two- or three-dimensional languages, in which information would be conveyed by other geometrical relations among the words. Thus, a two-dimensional language might use

Adam
Beth Carol

to express that Adam is above Beth and Beth is next to Carol. A three-dimensional language could use blocks as words and count three-dimensional placement of the blocks as semantically significant. Such possibilities inspire Wittgenstein to say that a sentence is a picture or model of reality (Proposition 4.021) and that hieroglyphic script indicates the 'essential nature of a proposition' (4.016). Consequently, what makes a proposition true is analogous to what makes a picture accurate: the meaningful elements of the proposition, that is, the names, must correlate with the objects in the (non-linguistic) fact it purports to describe; and the configuration of the names must be the same as the configuration of the objects in the represented fact. One-dimensional languages, such as English, tend to hide their true form (4.0031). Presumably, most human languages are one-dimensional because as a practical matter such sentences are easier to produce.[3]

Bertrand Russell developed a variation on Wittgenstein's naming theory. According to Russell, there are two kinds of names: proper names and common names. Proper names directly denote individual objects. For him, these individual objects are virtually always sense data, that is, sensations, in contrast with independently existing concrete objects such as tables, chairs, cats and dogs. Common names directly denote what philosophers have variously referred to as concepts, properties and universals. The difference between individuals and concepts can be explained with examples. In looking at a chalk board, a person sees a particular patch of black. This sensation is an individual. But this particular sensation of black is only one of many that can be seen either by the same person at different times or by many people at different times. These particular sensations of black have something in common; they are all instances of a certain general thing. That general thing is the concept, property or universal.

The distinction between individuals and universals gets reflected in language as the distinction between subjects and predicates. All and only proper names are subjects; all and only common names are predicates.[4] (The term 'common name' may be misleading because for Russell, adjectives and verbs are the paradigmatic cases of common names.) A sentence such as 'Socrates sits' is usually understood as having the subject 'Socrates' directly denote Socrates and as having 'sits' express the concept of sitting. The sentence is true just in case Socrates belongs under the concept of sitting.

Russell drew a sharp distinction between proper names and definite descriptions. Russell defined a definite description as any phrase of the form 'The ' (where is any noun or noun phrase) such as 'The tallest person in China'. In doing so, he was directly opposing the great nineteenth-century logician Gottlob Frege, who had grouped proper names and definite descriptions together as 'singular terms'. Both kinds of expressions, it seemed to Frege, could occur as subject expressions of sentences and had the same function, namely, to refer to the object of which a property was to be predicated. Also, both denote objects through some sort of cognitive or conceptual element, which he called *'Sinn'* (sense or significance). For example, the phrases 'the third from the left' and 'the second from the right' have different senses, yet each refers to the same thing if four objects are placed in a row. In short, Frege had a two-tiered semantic system: a realm of senses *(Sinne)* and a realm of referents *(Bedeutungen)*.

Russell had a one-tiered system. Since the meaning of a word is the object it directly denotes, names do not have any descriptive content *(Sinn)*. The name 'Socrates' does not reveal anything about what Socrates is like. Even a seemingly descriptive name such as 'Sitting Bull' is not descriptive. Sitting Bull is not a bull and does not need ever to sit, so far as the naming function of 'Sitting Bull' is involved. In contrast, Russell thought that a description does not directly denote an object and hence has no meaning. It denotes its object, if at all, through the mediation of the concepts expressed by it. For example, 'the evening star' denotes Venus through the concept of being the first celestial body to appear in the evening sky. One consequence of the differences just mentioned is that proper names cannot fail to denote an object while descriptions can.

Another consequence is that descriptions are never subjects. This is initially implausible since 'the present king of France' appears to be the subject of the sentence 'The present king of France is wise.' On the other hand, there is a problem with holding that the description is the subject of the sentence: there is no king of France. How can the sentence be meaningful, as it is, and yet not be about anything?

There are three basic ways out of this problem. One is to designate an arbitrary object, say, the null set, to serve as the referent of any description that does not naturally denote an object. This was Frege's suggestion, and Russell rejected it as *ad hoc* and artificial. A second way is to maintain that there are non-existent beings that are actually denoted by such words and phrases as 'the present king of France', 'the golden mountain' and 'the largest natural number'. Russell himself had accepted something like this view in *Principles of Mathematics* (1903), but railed against anyone who should take such a position after he found a way around it. In *Introduction to Mathematical Philosophy* (1919), he writes: 'The sense of reality is vital in logic, and whoever juggles with it…is doing a disservice to thought. A robust sense of reality is very necessary in framing a correct analysis of propositions about unicorns, golden mountains, round squares, and other such pseudo-objects' ([1.28], 170).

The third way out of this problem is Russell's. He explains why 'the king of France' is not the subject of the sentence and further that, despite appearances, 'The present king of France is wise', is not a subject-predicate sentence. According to Russell, the sentence 'The present king of France is wise' is actually a complex existential sentence. That is, the sentence is correctly understood as saying something like the following: 'There exists an object x such that x is-male-and-monarchically-reigns-over-France;[5] nothing other than x is-male-and-monarchically-reigns-over-France; and x is wise.' Notice how the noun phrase 'king of France' has been eliminated altogether and its conceptual content has been transformed into a property, which is expressed by the principal verb phrase ('is-male-and-monarchically-…').

Russell presumably came up with this analysis of sentences in which definite descriptions occur by thinking about the conditions under which the sentence would be true. A sentence of the form 'The is ' is true (roughly) if exactly one object has the property expressed by and also the property expressed by . Another way of saying that exactly one thing has a property is to say that at least one thing has it and at most one thing has it. The first two clauses of the analysans are supposed to capture this idea of exactly one object having a property.

One of the reasons that philosophers found Russell's theory of descriptions attractive was that it could be extended to handle problems that involved what seemed to be proper names. Consider this paradox:

The paradox of reference and existence

(1) Everything referred to must exist.
(2) 'Pegasus' refers to Pegasus.
(3) Pegasus does not exist.

Propositions (1)–(3) are paradoxical because they are jointly inconsistent and yet each seems to be true. Propositions (1) and (2) entail

~ (3) Pegasus exists.

Proposition (1) has been called 'The axiom of existence' because its truth seems axiomatic. Concerning (2), what could 'Pegasus' refer to except Pegasus? Concerning (3), the sense of reality that Russell urged philosophers to maintain forces one to affirm that Pegasus does not exist.

Russell's solution to the paradox is in effect to deny (2). 'Pegasus' does not refer to Pegasus, because 'Pegasus' is not a genuine or logically proper name. Indeed, no ordinary proper name is a genuine proper name. Proper names do not directly denote, even when they do fit an object. Rather, they are disguised or abbreviated descriptions. 'Pegasus', for example, is a disguised description for 'the flying horse'. A sentence such as 'Pegasus was captured' should then be understood, according to Russell, as meaning 'There exists an object *x* such that *x* is equine and flies, whatever is equine and flies is identical with *x,* and *x* was captured.' Since nothing is equine and flies, this sentence is false. According to Russell all of the sentences of mythology and fiction are false.

If ordinary proper names are not genuine names, what are? For some years after the publication of 'On Denoting' in 1905 Russell thought that 'this', 'that' and 'I' were proper names, because they seemed to directly denote some object that was 'ostensively' defined (pointed to). But eventually he came to think that 'this' was a disguised description for 'the object that is close to the speaker and being pointed to'; 'that' was a disguised description for 'the object that is remote from the speaker and is being pointed to'; and 'I' a disguised description for 'the one speaking'. Ironically, the initial contrast between proper names and definite descriptions, which justified his elaborate theory, collapses; and Russell concludes that nothing is a proper name.

Russell's theory is intuitively implausible, and the editor of *Mind* was reluctant to publish it. Nonetheless, within a short time, it came to be regarded as a brilliant piece of philosophical thinking because it offered precise solutions to the problems it addressed.

It was not until 1950, when P.F.Strawson published 'On Referring,' that the cogency of Russell's theory was seriously challenged. Strawson maintained that the sentence 'The present king of France is wise' is not only grammatically, but is logically a subject-predicate sentence, and that the sources of Russell's mistakes were fundamental confusions about language.

Strawson denies the basic claim of the naming theory of meaning. He says that the meaning of a word is never the object it is used to refer to. Sometimes the word 'mean' means 'refer'; for example, in the sentence, 'Jones meant George Eliot when he said that the greatest English novelist was a woman.' But in these cases, what is at issue is what the speaker meant and not what a word meant. If the meaning of a word were the object it referred to, then to take a handkerchief out of one's pocket would be to take the meaning of 'handkerchief out of one's pocket. Also, to destroy a named object would be to destroy the meaning of a name. Each of these consequences is absurd.

As an alternative to the naming theory, Strawson adumbrates what is sometimes known as the use theory of meaning, which was extremely influential from the early 1950s until the early 1970s. He says, 'To give the meaning of an expression…is to give *general directions* for its use to refer to or mention particular objects; to give the meaning of a sentence is to give *general directions* for its use in making true or false assertions.'[6] (See chapter 8 in this volume for a further discussion of this idea.)

Strawson draws a sharp line between sentences and statements. Sentences can be grammatical or meaningful, but they are neither true nor false. It is not the sentence but the statement or assertion that is

made by using the sentence to represent the world that is true or false, according to Strawson. To think that the sentence 'The present king of France is wise' is either true or false simply because it is meaningful is absurd. Used in 1625, that sentence could have been used to make a statement about Louis XIII; used in 1650, it could have been used to make a statement about Louis XIV. But these are obviously two different statements, resulting from utterances of one and the same sentence. Used in the twentieth century, 'The present king of France is wise' cannot result in any statement at all even though it remains meaningful. Today a benighted speaker of the sentence could try to make a statement with that sentence but would fail. According to Strawson, it is not words that make statements or refer, but people. Consequently, the question, 'To what does the subject expression of the sentence "The present king of France is wise" refer?' should not arise.

Behind Strawson's objections is a view of language that is radically different from Russell's. For Russell, words and sentences are the fountains of meaning. For Strawson, people using words and sentences are. For Russell, semantics is the primary object of linguistic study. For Strawson, it is pragmatics, how people use words. Strawson's arguments in 'On Referring' were a harbinger of much work to be done between 1960 and 1980. Before discussing that work we need to look at further developments in semantics in the 1920s and 1930s.

THE VERIFICATION THEORY OF MEANING

The naming theory of meaning takes names as the primary locus of meaning. A different view is held by the logical positivists. For them, the primary locus of meaning is the sentence.

Logical positivism flourished first in central Europe during the 1920s and early 1930s and then in England, the United States and Scandinavia from 1930 until the early 1950s. The original logical positivists were the philosophically oriented scientists and mathematicians who formed the Vienna Circle under the leadership of Moritz Schlick. Soon, most logical positivists were neither scientists nor mathematicians but were *scientistic* in the sense that they believed that only science discovers the truth about reality. They thought that metaphysics in contrast with science had hindered intellectual progress, and one of their goals was to discredit that once venerable area of philosophy.

With regard to the philosophy of language, logical positivists thought that meaningful sentences could be divided into two groups: those that were cognitively meaningful and those that were emotively meaningful. Although the cognitively meaningful sentences held pride of place, let's first deal with the others. Sentences that belong to ethics, aesthetics, politics and religion—in short, value-laden sentences—were thought to have what was called 'emotive' meaning. According to the logical positivists, such sentences were not intended to describe how the world is but to express or to induce some attitude or emotion. Thus, to say, 'Honesty is the best policy', 'That picture is beautiful', 'Democracy is the best form of government', or 'God is the creator of the universe', either is to express some positive attitude or emotion that the speaker holds or is intended to induce such in the audience. Sentences such as 'Lying is wrong' either express or are intended by their speakers to induce some negative attitude or emotion. There is undoubtedly some truth to this sort of account of value-laden language; but the account did not seem to present an adequate theory of such talk in general. Other philosophers tried to round out the picture by arguing that to say that something was good was to recommend or to commend it.

Although some of them thought seriously about value-laden language, most logical positivists had a dismissive attitude towards it. For them to distinguish such language was important in order to ensure that it was not confused with the only kind of language that was cognitively meaningful, namely, the language of science and logic.

Cognitively meaningful language consisted of two types of sentences: sentences of logic and empirical sentences. The sentences of logic were themselves of two kinds: tautologies and contradictions. Tautologies (sometimes known as analytic sentences) were sentences that had to be true, e.g. 'Either it is raining or it is not raining.' Contradictions, e.g. 'It is raining and it is not raining', were sentences that had to be false. Tautologies and contradictions have the truth-values that they do in virtue of the meanings of the words that compose them and independently of how the world is. Empirical sentences, in contrast, are true or false depending upon how the world is. The meaning of an empirical sentence determines what fact about the world makes it true (if it is true) and what fact or possible state of affairs makes it false (if it is false). For example, the meaning of 'The cat is on the mat' determines that the sentence is true if and only if it is a fact that the cat is on the mat.

It is not difficult to judge that 'The cat is on the mat' is an empirical sentence, that is, a sentence that purports to describe the physical world. Further, it may seem that it should not be difficult to characterize what an empirical sentence is. Nonetheless, the effort to characterize what an empirical sentence is was a total failure and led to the downfall of logical positivism.

The original motivating idea was that a sentence is meaningful[7] precisely when it is verifiable; that is, precisely when there is a method for determining whether it is true. This criterion of meaning inspired the slogan that the meaning of a sentence is its method of verification. The criterion also seemed to have the desired effect of excluding sentences of metaphysics from the realm of the meaningful ones. There is no way to verify the sentences, 'The Transcendental Ego is absolute', or 'Nothing nothings.' They are therefore adjudged meaningless by the verifiability criterion of meaningfulness. This result pleased the logical positivists, who thought of metaphysics as the antithesis of science.

Unfortunately for the logical positivists, the verifiability criterion is too strong because it rules out many sentences that they considered meaningful. For example, sentences that are formulated as universal propositions are not conclusively verifiable. Consider a straightforward sentence like 'All humans are mortal.' It is surely meaningful and everyone considers it true. All the individual instances of human beings who have died are empirical evidence for its truth. Nonetheless, there is no empirical guarantee that everyone now alive will die. Thus, the evidence of previous deaths does not conclusively establish the truth of the universal sentence.

Logical positivists responded to this and other challenges in various ways. All agreed that the original verifiability criterion did not work. One alternative to it was a falsifiabilty criterion; that is, a sentence is meaningful precisely when there is a method of determining when it is false. Affirmative universal sentences are meaningful on this criterion. But another kind of sentence is not, namely, universal negative sentences such as 'There are no unicorns.' Although there is no positive evidence for the existence of unicorns (and no sensible person thinks that unicorns exist), there is no evidence that could conclusively falsify that sentence. Even though no unicorn has ever been observed, it is conceivable that this is due to the fact that one lives in a remote region and moves too quickly to be seen.

A more popular way to circumvent the problems with the verifiability criterion was to revise it in ways that would avoid the counter-examples. For example, full verification was replaced with the idea of partial verification. None of these revisions worked. Many of them allowed metaphysical sentences to count as meaningful, contrary to the intentions of their authors. Another problem with the verifiability criterion is that it is self-refuting. By its own criterion, no statement of verifiability is itself meaningful. Such a statement cannot be a proposition of logic since it is supposed to be a substantive truth; and it cannot be an empirical proposition since it does not describe the world. Indeed, the various statements of the verifiability criterion devised by logical positivists seemed to be metaphysical sentences. This realization led most

philosophers not only to abandon the search for an empirical criterion of meaningfulness, but to abandon logical positivism.

UTTERER'S MEANING

Until the late 1950s, virtually all work done in the philosophy of language assumed or presupposed that the primary locus of meaning was in words or sentences. Philosophy of language was almost synonymous with semantics. Any connection that people had to language was thought to be within the purview of psychology. Much of Strawson's criticisms of Russell's theory of descriptions was grounded in a diametrically opposed view of language. For Strawson, the focus of the philosophical study of language was on people and what people do with language. However, Strawson did not present a well-developed alternative to the prevailing theory of meaning. The alternative was publicly presented in 1957 by Paul Grice, who had been Strawson's teacher and later his colleague at Oxford.

In 'Meaning' [1.14], Grice aims to explain what meaning is when meaning concerns communication. For example, he is interested in meaning as the concept that is expressed in the following sentences:

> The ringing of the bell means that the bus is full.
> By raising her hand, Mary meant that she knew the answer.
> That remark, 'The coast is clear', means that the rebels have left.

Grice calls this 'nonnatural meaning.' This term is something of a misnomer since there is nothing unnatural about the kind of meaning he has in mind. It might better have been called 'communicative meaning', because Grice is interested in what is required for people to communicate with each other in a very broad sense. Linguistic meaning is a narrower concept that fits under the general category of non-natural or communicative meaning. Communicating through hand signals, flags and other non-linguistic gestures is obviously communication but not linguistic communication.

Grice's motivating insight is that for a person to mean_{NN} (non-naturally) something is for that person to engage in a complex kind of intentional behaviour that is directed towards another person. In short, he argues for the following analysis: a person means_{NN} something by some thing or action if and only if the person intends to produce some effects in an audience by getting the audience to recognize through that thing or action that he intends that effect. Grice thinks that there are basically two kinds of effect that a person can induce in an audience: a person can get an audience to believe something; and a person can get an audience to do something. In language, these two kinds of communication are reflected in the existence of the indicative mood ('Mary opens the door') and the imperative mood ('Mary, open the door'), respectively.

The crucial point in this analysis is the idea that the way in which the effect is achieved in the audience is by recognizing the intention of the speaker. An audience comes to the belief that the utterer is leaving simply by recognizing that the utterer, by waving his hand in the way that he does, intends him to believe this. In talking about intentions, Grice does not want to commit himself to a special kind of mysterious, unobservable entity. Intentional behaviour is a certain way of behaving; it is not behaviour plus some unseen mental object. Thus, he thinks that intentional behaviour is as open to empirical methods of investigation as any other.

SPEECH ACTS AND CONVERSATION: A THEORY OF PRAGMATICS

Grice's theory of meaning is general enough to apply to any kind of communication, not only linguistic communication. J.L.Austin, a colleague of Grice at Oxford, developed a theory that in effect complements that of Grice by dealing with specifically linguistic aspects of communication. Austin first formed his theory in 1939, but it was not until 1955, when he presented his views at Harvard in the William James Lectures, that it became widely known. The lectures were later published as *How to Do Things with Words* (1962).

Austin's views originated as an elaborate attack on two related philosophical positions: that there is a difference between talking and acting; and that all talk aims at describing the world. The second position is characteristic of logical positivism in so far as it holds that every cognitively meaningful sentence must be empirically verifiable. Austin refutes this latter position by giving several counter-examples, each of which is a sentence containing only garden-variety words— that is, no evaluative, emotive or metaphysical terms: 'I name this ship the *Queen Elizabeth*'; 'I bequeath my watch to my brother'; 'I bet you five dollars that it will rain tomorrow.' These counter-examples direct attention back to the first philosophical position. What is characteristic of the counter-examples is that expressing them is equally talking and acting, or, to vary the formula: a saying and a doing. To put the point another way, there are many actions that are typically achieved by performing a speech act.

It may appear that although some talking is also acting, there is nonetheless an important distinction to be drawn between two kinds of talk: descriptive talk and non-descriptive talk. Statements and assertions have as their goal the correct description of reality; those that succeed are true, and those that fail are false. Austin calls such utterances 'constative'. In contrast, christening, bequeathing, betting, and the like do not have the goal of describing anything. They are neither true nor false. They have as their goal the performance of some action. Austin calls such utterances 'performative'.

The constative/performative distinction, founded as it is on the descriptive/non-descriptive distinction, would seem to be unshakeable. One of the features of Austin's genius is his dialectical destruction of this seemingly unexceptionable distinction. Attacking the idea of a constative, he shows that making a statement requires that certain conditions be satisfied that are strictly analogous to conditions for performative utterances. In order to make a statement, a speaker must have evidence for it; it must be relevant to the context of its utterance; and for many purported statements there must be an object of reference. Thus, there are many ways in which an attempt to make a statement can fail; and when there is a failure, the (attempted) statement fails to describe anything and is neither true nor false.

Focusing next on the idea of a performative, Austin shows that many performative utterances have a descriptive aspect. Consider, 'I bet that Cleveland will win the pennant', or 'I promise that Mary will be at the meeting.' The clauses, 'Cleveland will win the pennant' and 'Mary will be at the meeting', are fully descriptive and can be assigned truth-values, but they are an essential part of the performative utterance. Thus, the distinction between performative and constative is again undermined.

The complete breakdown of the constative/performative distinction is evident if one tries to categorize the sentence, 'I state that the cat is on the mat.' On the one hand, this sentence appears to be a paradigm case of a constative; it seems to say of itself that it is a statement. On the other hand, it has the very same structural form as paradigmatic cases of performative utterances ('I bet that *p*' and 'I promise that *p*'). Further, it appears that what is true or false is not what is expressed by the sentence as a whole ('I state…') but only what is expressed by the dependent clause, namely, that the cat is on the mat.

The breakdown of the constative/performative distinction leads Austin to develop a new theory of discourse or speech acts. He distinguishes between three different levels or aspects of speaking: the locutionary, the illocutionary and the perlocutionary. The locutionary act itself contains three component parts: linguistic entities can be thought of (1) as sounds (or typographical marks), (2) as words belonging to

a language and (3) as having reference to things in the world and a meaning or significance. The illocutionary act consists of the *force* of the utterance, whether it be a bet, promise, statement, conjecture or something else. The perlocutionary act relates to the effect that is induced in the audience. Persuading, infuriating, calming or inspiring someone are perlocutionary acts. They can be intended or unintended, but what distinguishes perlocutionary from illocutionary acts, for Austin, is that while illocutionary acts always rely upon the existence of conventions, perlocutionary acts are natural or non-conventional.

Austin's work re-oriented the research of many philosophers and laid the groundwork for the standard theory of speech acts, which was developed by his student, John Searle. Searle first adumbrated his views in 'How to promise: a simple way' (1964) and then elaborated them in *Speech Acts* (1969).

Searle has shown that Austin's distinction between locutionary and illocutionary acts does not cut speech at a joint. He argues that paradigmatic cases of speech acts are illocutionary acts that express both a force and a content. Consider the sentences,

I state that Mary will be at the meeting.
I question whether Mary will be at the meeting.
I bet that Mary will be at the meeting.
I promise that Mary will be at the meeting.

Each of these sentences expresses the same content, namely, the proposition that Mary will be at the meeting. This proposition consists of a referent (Mary) and a predication (being at the future meeting). While Austin thought propositions, which he called 'the locutionary act', were complete entities, Searle shows that they are part of the illocutionary act. The other part of the illocutionary act is its force. The proposition (that Mary will be at the meeting) acquires a different force with the utterance of each sentence above. It is variously stated, questioned, bet or promised.

Searle noticed that there are different kinds of conditions that need to be fulfilled for different speech acts. For example, there are conditions on the kind of proposition that can be expressed in certain speech acts. Promises and commands require propositions about the future. Condolences presuppose a proposition about the past. Any condition that concerns the proposition or content of the speech act Searle calls 'a propositional content condition'. Virtually every speech act requires certain things to have preceded the speech act. For example, a promise requires that the speaker be able to do what he will promise to do; a request requires that the addressee be able to do the thing to be requested. Such conditions are called 'preparatory conditions'. Many speech acts require some kind of sincerity on the part of the speaker. Stating requires that the speaker believe what he is saying; promising requires that the speaker intend to do what he promises; requesting requires that the speaker want what he requests. Such conditions are called 'sincerity conditions'. Every speech act has an essential condition, which specifies what the point or purpose of the speech act is. The point of a statement is to describe the world; the point of a question is to get information; the point of a request and a command is to get the audience to do something.

The theory of speech acts tends to study the use of individual sentences. However, there are overarching principles that govern all conversation. The role that these principles play in conversation has been studied by H.P.Grice. Since communication is a co-operative enterprise in which the speaker tries to get the audience to understand what he or she has in mind and the audience does its part to understand the speaker, certain maxims standardly operate. Speakers are to say what they believe to be true and they should have evidence for what they say. They should say as much as is necessary and not more. What they say should be relevant to what has gone before. Finally, they should formulate what they have to say briefly, clearly, unambiguously and in an orderly way. Although these conversational maxims are the norm, they can go

unfulfilled in a variety of ways. Sometimes people *violate* maxims; that is, they quietly and unostentatiously fail to fulfil one, not only when they lie, but when they make an honest mistake or misconstrue the direction of the conversation or presuppose more than they should. Sometimes people *opt out of* fulfilling a maxim. This is often required when two maxims clash in a particular situation. Someone who is asked to give a brief and clear explanation of Immanuel Kant's transcendental deduction of the categories may say, 'I can't give a brief explanation of it.' Sometimes people *flout* a maxim; that is, they openly and ostentatiously do not fulfil one. Figures of speech employ flouting. Meiosis flouts the maxim to say as much as necessary, for example, saying, 'There's some clean up to be done here', after a devastating hurricane. Ironic utterances such as, 'You're a fine friend', said after being betrayed by a friend, flout the maxim to say what one believes. Metaphor involves flouting the same maxim. To say metaphorically, 'My love is a red rose', is not to assert that one's lover is a certain kind of flowering plant. Thus conversational maxims can go unfulfilled in at least three ways: by being violated, opted out of or flouted.

The most important aspect of Grice's theory of conversation is his explanation of how the interaction of what a speaker says (or pretends to say), the conversational maxims and the context gives rise to 'conversational implicatures'. That is, speakers communicate much more to their audiences than what they say or what is logically implied by what they say. If a speaker says, 'There's a gas station around the corner', to a person whose automobile has run out of gas, then the speaker has implied that the gas station is open and has gas available even though he has not said as much. If a speaker says, 'Well, Smith tries very hard', and nothing more to a person who has asked about whether Smith is a good candidate for a job, then he is suggesting that Smith is not a good candidate.

Grice and other philosophers have shown that his simple observations about how language functions can be helpful in solving many traditional philosophical problems in epistemology, semantics and even ethics. To take a simple example (although Grice himself did not agree with this particular application), consider Moore's paradox. There is something odd about the sentence, 'It is raining and I do not believe that it is raining.' The sentence is not contradictory, and yet it is difficult or impossible to think of circumstances in which someone could seriously utter such a sentence. To assert such a sentence would usually be absurd, and yet, if it were asserted, it might say something true. A solution that appeals to Grice's theory explains that the sentence is odd because the assertion of the first clause conversationally implies 'I believe that it is raining' and that contradicts the second clause 'I do not believe that it is raining.' Thus, although the semantic content of Moore's sentence is not contradictory, what would normally seem to be communicated by the sentence is contradictory, and people communicate contradictions only in very special circumstances.

THE CAUSAL THEORY OF NAMING

Although the 1960s and 1970s were the heyday of pragmatics, Russell's theory of descriptions and his view that the semantic connection between genuine proper names and what they denote is direct (unmediated) received renewed support. We have already mentioned that Russell's theory of descriptions was the favoured way of dealing with problematic referring expressions until 1950. From 1950 until the middle 1960s, Strawson's treatment of referring had the upper hand. The publication of Keith Donnellan's article, 'Reference and Definite Descriptions', in 1966 introduced a new element into the theory of reference [1.12].

Donnellan thought that among the various uses of definite descriptions, there were two that were relevant to the dispute between Russell and Strawson: the attributive use and the referential use. The function of the referential use, on which Strawson had focused, is to get the hearer to pick out an individual that the speaker

has in mind. If, intending to get the audience to think that Jones is insane, a speaker uses the sentence, 'Smith's murderer is insane',[8] then the definite description is being used referentially. The proposition expressed by the utterance can be represented as the ordered pair (Jones, being insane). This proposition would be true, according to Donnellan, just in case Jones is insane, whether or not Jones murdered Smith.

Donnellan's point can be illustrated by considering the following case. Suppose that Jones is on trial for the murder of Smith, a gentle and well-respected person, who was killed in a particularly brutal fashion. Further suppose that Jones in fact did not kill Smith but is insane. On the basis of Jones's bizarre behaviour in the courtroom, someone says, 'Smith's murderer is insane.' In such a situation, according to Donnellan, the speaker has successfully referred to Jones and has correctly said that he is insane even though the phrase used to refer to Jones does not fit him. The speaker successfully referred to Jones because of his intention to use the phrase to pick out Jones.

In contrast with the referential use, if a speaker uttered the very same sentence and did not intend the audience to pick out Jones or any other person that he has in mind but only intended to make a general comment about anyone who would murder as gentle a person as Smith, then the definite description would be used attributively. The proposition expressed by the utterance can be represented as the ordered pair (being the murderer of Smith, being insane). This proposition would be true just in case exactly one person murdered Smith and was insane. Obviously the truth-conditions are different. As the example about Smith and Jones illustrates, whether a description is being used attributively or referentially depends upon the speaker's intentions and context.

The upshot of Donnellan's distinction is that referring to an object does not require that the word or expression used has a descriptive content that fits the object referred to. Donnellan then applies this result to proper names. They do not have or in any way rely upon any descriptive content. In other words, ordinary proper names function the way that Russell claimed that logically proper names do. Thus, contrary to what Russell thought, ordinary proper names are logically proper names. Donnellan described his views as 'an historical account of referring'. He explained that a proper name refers to the object that it does because it is connected to that object through all the previous uses of that name to refer to that object. Since his explanation of referring uses the notion of referring, it should be clear that he did not intend to present a theory of what referring is, but an explanation of how a proper name refers to the object that it does, rather than to some other object.

Contemporaneously with Donnellan, Saul Kripke was developing a similar account of referring, which he called 'a causal account of referring' [1.17]. Like Donnellan, Kripke was interested in how the use of some name, such as 'Aristotle' picks out Aristotle rather than someone else. Much of Kripke's effort is devoted to attacking the description theory of proper names. According to that theory, proper names could not directly denote the object that they name, because there would be no way to connect a name to its object. Thus, according to this theory, each proper name must be associated with or connected to some more or less determinate cluster or disjunction of descriptions which is true of the named object and nothing else. Both the speaker and audience use the descriptive content of a name to pick out the object named. In short, to know the meaning of a proper name is to know what cluster of descriptions picks out a uniquely named object.

Kripke objects to the description theory on two main grounds. First, for very many names most people do not associate any uniquely identifying cluster of descriptions with the object named. For example, 'Cicero' for most people is *a* famous Roman orator, not *the* most famous Roman orator. Second, a person may know how to use a proper name even if the set of descriptions that he or she associates with the named object do not in fact correctly describe it. Suppose that the name 'Aristotle' is associated with this disjunctive cluster of descriptions: 'either the student of Plato, or the teacher of Alexander, or the author of *Metaphysics* and

De Anima'. But further suppose that Aristotle was a fraud; that he did none of the things attributed to him but invented them through an elaborate ruse, which has never been detected by historians. Nonetheless, 'Aristotle' is the name of Aristotle, even though the descriptions associated with him are wholly false.

According to Kripke, the reason why 'Aristotle' picks out Aristotle is that there is a causal connection between the speaker's use of 'Aristotle' and Aristotle. At some point in the use of the term 'Aristotle', some speaker succeeded in referring to Aristotle by that name— Kripke suggests that this occurs in baptismal or analogous ceremonies —and that success has been passed on from speaker to speaker down to this very day. Obviously, this account of referring does not explain what referring itself is. It presupposes that referring has occurred in past uses of the name. What it purports to give is an account of how *the reference is fixed* of a name currently in use.

Various philosophers have pointed out that Kripke's account is flawed. There are many cases in which the causal chain of a name's use has gone awry. 'Madagascar', to mention one instance, originally was the name of part of the African mainland. The island acquired that name because Marco Polo mistook the reference. Native Americans received the name 'Indians' because Columbus mistakenly thought he had reached India. In short, the causal chain connecting a current use with the original use of a name does not alway determine the correct reference.

Kripke extends his views about proper names to common nouns that denote natural kinds, that is, to words like 'gold', 'dog' and 'tree': natural-kind terms denote their objects because of a causal, communicative tie between the word and the objects and not because of any descriptive content that the speaker may associate with it. Hilary Putnam developed a very similar view. Putnam's colourful way of putting this was to say that '"meanings" just ain't in the head'.[9]

According to Putnam, common nouns have the reference or extension that they do because of a causal tie between the use of the word and the object referred to. 'Water' refers to water because in its paradigmatic uses people supposedly point to it and say, '*This* is water.' In other words, common nouns function in a way similar to proper names. Both are what Kripke calls 'rigid designators', that is, terms that pick out the same object in every possible world in which they exist.

Traditionally, common nouns were thought to denote or refer to objects indirectly, through a concept. Thus, a speaker who used the word 'gold' would expect his audience to know what object he was talking about because both the speaker and the hearer had a concept that was descriptive of gold and nothing else (for example, 'the yellowish, valuable metal, that dissolves in *aqua regia*') and by which a person is directed to gold. In Frege, this descriptive concept was called 'sense' *(Sinn);* in Locke, it was called 'an idea'. In scholastic terminology, the difference between the concept associated with a noun and its reference was the difference between intension and extension.

Putnam argues that there could be a planet (Twin Earth), which is just like Earth except that instead of water it contains a liquid that has the same gross properties of water—that is, the same taste, odour, smell, appearance and viscosity—but a completely different chemical composition. Because the gross properties of each liquid are the same, a person on Earth and a person on Twin Earth would seem to be in exactly the same mental state; yet they would be referring to different liquids. Consequently, a person's ideas or concepts of an object cannot determine what it is that he or she refers to.

One of the consequences that Putnam draws from his study of common nouns is that language use involves a division of labour. Water is all and only that which has the chemical composition of H_2O. Although virtually every speaker of English can use the word 'water' competently, some speakers of the language need to have the requisite technical knowledge to determine the genuine reference or extension of 'water'. Thus, a further consequence is that using a language is much more of a co-operative enterprise than is usually thought.

NAMES AND BELIEF

In 1979, Kripke argued that neither the description theory of names nor his own causal account of names can solve the following problem about Pierre. Pierre is born and raised in France and initially knows how to speak only French. On the basis of what he is told about London, he forms the belief that London is pretty. Since he speaks only French he says or would think to himself 'Londres est jolie.' Not knowing English, Pierre does not and could not express his belief using the sentence

(1) London is pretty.

Later, Pierre leaves France and takes up residence in a squalid part of a city in another country. It is London. There he learns English as a native would, that is, with direct interaction with his local environment and without directly learning how to translate back and forth between English and French. In particular, he never learns that 'London' and 'Londres' name the same city. On the basis of his experience in London, he forms the belief that is expressed by

(2) London is not pretty.

The question is whether Pierre has contradictory beliefs. It would seem that he does since he would sincerely assert 'Londres est jolie', which means the same as (1) and would sincerely assert (2). But Kripke thinks it is impossible that Pierre has contradictory beliefs; for Pierre is a distinguished logician who 'would *never* let contradictory beliefs pass'.[10]

Most proposed solutions to this puzzle try to explain how it is that Pierre has contradictory beliefs and is not aware of them. What lies behind Kripke's denial that Pierre has contradictory beliefs is something like the following principle.

> **Nominal Transparency:** If (1) the semantic connection between a term and the object it denotes is direct (unmediated), (2) terms *x* and *y* denote the same object o, and (3) a person *p* is competent to use both *x* and *y,* then *p* must be aware of any contradictory beliefs that *p* has when *o* is represented by *x* and *y*.

Kripke thinks that his arguments in *'Naming and Necessity'* [1.14] proved clause (1); and he thinks clauses (2) and (3) are as a matter of fact satisfied by Pierre and his linguistic knowledge.

We can agree that all three clauses are correct and still deny that the consequent of nominal transparency is true. Kripke's mistake in part is, I believe, to think that a semantic connection is the only connection that is relevant to the ability to use a name. As a matter of fact, in order to be able to use a name, a person also needs to have some mental representation that connects the name with the object, but this representation is not a part of the meaning of the name. It cannot be part of the meaning of the name, because how people represent an object to themselves is not uniform, and individuals can change how they represent objects without any loss in their ability to refer to those objects. It need not interfere with their ability to communicate if one interlocutor thinks of Aristotle as the student of Plato and the other thinks of Aristotle as the teacher of Alexander. Similarly, it need not interfere with communication if a person thinks of Aristotle at one time as the student of Plato and at another time as the teacher of Alexander.

If people were aware of all the logical relations that held between the various ways that they mentally represent objects, then if two names named the same object, they would be aware of it. But many of these relations are opaque to the person who has them. The contents of (at least very many) beliefs are not immediately accessible to people, but only through their mental states or representations, which present the object from a perspective and not *in toto*. These limited perspectives often prevent people from recognizing all the consequences of their beliefs. It is the mental analogue of a person who sees an elephant from the front and later from behind and infers that he or she has seen two kinds of animal.

Perhaps behind Kripke's puzzle is an even more general misconception about language: the belief that language is self-contained and that purely linguistic knowledge is sufficient for using language. Both of these assumptions are under attack by the philosophers who will be discussed in the next section.

INTERPRETATION AND TRANSLATION

Most philosophers who have thought about language have focused on the utterer's role in communication. One might expect that looking at communication from the audience's point of view should not present a very different perspective if discovering what the utterer is doing is exactly what the audience does. As a matter of fact, these are very different perspectives. W.V.Quine is perhaps the first and certainly the most important Anglo-American philosopher to look at language from the audience's perspective.

In *Word and Object,* published in 1960, Quine explores the consequences of an uncompromisingly naturalistic view of language [1.20]. Only physical facts are relevant to understanding linguistic behaviour, and all the evidence humans have for thinking of something as language and for attributing significance to those utterances is purely empirical. This does not mean that the judgements that people make about linguistic behaviour are exclusively empirical. Judgements about linguistic behaviour are a mixture of empirical evidence and explanatory hypotheses. This latter point was the principal lesson of his classic article, 'Two Dogmas of Empiricism' [1.23]. Rather than as a pure empiricist, Quine thought of himself at this time as a kind of pragmatist. Later, he would think of his philosophy as empiricist, pragmatic and naturalistic.

Quine asks how an audience can come to understand what a speaker of an utterly foreign language means. The problem is to figure out how a person would correlate sentences of his or her own language with sentences of the speaker's language. Quine develops his answer picturesquely by describing 'a field linguist' coming upon 'a native'. He supposes that the native utters, 'Gavagai', as a rabbit runs by. The issue is, how does the linguist (the audience) understand what the native has said? Quine thinks that the linguist must ask the native questions. This of course implies that the linguist has formulated some hypothesis about what kind of behaviour corresponds to saying 'yes' in English and what kind corresponds to 'no'. These hypotheses are part of a complicated web of hypotheses that are devised with the goal of arriving at the most plausible understanding of the behaviour of the natives. Even if the native used the vocables 'yes' and 'no', the linguist could not simply assume that the native's 'yes' means the same as his or her own 'yes'. The native may mean just the opposite by these vocables. Nor could the linguist simply assume that the nod of the native's head means 'yes', or that shaking it means 'no'. Again, the native could mean just the opposite or something else. The native could have some completely different convention, such as exposing the right index finger for 'yes' and the left index finger for 'no'. So the actual process of hypothesis formation is quite complex.

The linguist has other difficulties. Suppose that the native often utters 'Gavagai' when a rabbit is present. The linguist may hypothesize that the proper translation of 'Gavagai' is 'Rabbit' (or 'There's a rabbit'). But how can the linguist be sure? Even if the linguist has settled on a hypothesis about how the native indicates 'yes' and 'no' the native's answer does not favour the linguist's proffered translation any more than it favours the translation 'More rabbit'; or 'There's an undetached rabbit part', or 'There's a temporal slice of a rabbit.' One way to determine whether 'Gavagai' refers to rabbits or undetached rabbit parts would be to point successively to two parts of the rabbit and ask the native whether the one *gavagai* is the same as the other *gavagai*. Of course, the whole thing must be said in the native's language. Suppose the linguist uses 'Gavagai plink gavagai' to express this. How can the linguist know whether 'plink' means 'is the same as' or 'is an undetached part of the same rabbit'? The linguist will get an affirmative response if 'plink' has

either meaning. Quine claims that no matter how many checks the linguist may try to place on his or her translation by testing other sentences in other situations, there is no one correct translation of all the sentences. It is always possible that there are several incompatible ways of translating the sentences of the language, each translation of which fits the empirical data. In short, translation is indeterminate.

Whatever translation scheme is adopted, it will be the result of a system of hypotheses that takes into account not only what words and sentences of one language correlate with words and sentences of another, but under what conditions the observed sentences were uttered and what beliefs and intentions the speakers had at the time. That is, the translation scheme presupposes certain judgements about what the empirical evidence was, and the translation of any individual sentence will make sense only within the entire theory of translation and evidence. This view that linguistic meaning resides in the entire language and not in any sub-unit such as a word or sentence is known as linguistic holism.

Because Quine thinks of the audience's goal as the correlation of sentences of one language with sentences of another language that is completely unrelated in evolution to the first, he calls the linguist's project 'radical translation'. Although it may seem that Quine thinks of translation as a purely syntactic enterprise: utterances ('sequences') of one system are correlated with utterances of another system, that is not quite correct. The primary sentences of a language are those that are tied to observable things: 'Mama' uttered in the presence of a mother, 'Red' uttered in the presence of red or 'Rabbit' uttered in the presence of a rabbit. So some words and the rest of the world are related in this way. What Quine objects to is the notion that meanings are determinate, abstract entities, which attach individually to sentences.

Quine's insights about language have been revised and extended by his student, Donald Davidson. One of the important revisions is a tacit criticism. Davidson does not think that the search for a translation manual between languages is crucial. One might know that 'Es regnet' is the correct German translation for the Italian sentence 'Piove' without knowing what either sentence means. So merely knowing how to translate between sentences in this narrow sense does not constitute knowing a language. Knowing how to interpret a language does. Thus, Davidson explores the explicitly semantic idea of 'radical interpretation', which is the project of determining how a person figures out the conditions under which an utterance is true. In this regard, Davidson acknowledges his debt to Alfred Tarski, who made semantics philosophically respectable. Davidson claims that since to know the meaning of a sentence is to know its truth-conditions (the conditions under which it is true or false), to have a theory of truth is to have a theory of meaning. Davidson differs from Tarski in that Davidson takes truth as a basic notion that does not need to be defined and uses it to explain what an interpretation is, while Tarski assumed that there was no problem in coming up with translations of sentences and gave a definition of truth.[11]

In 'Belief and the Basis of Meaning', published in 1974, Davidson makes it clear that a basic difficulty in interpreting a speaker's words is that interpretation is not simply the task of assigning meanings to utterances [1.8]. Interpretation involves at least two interdependent activities. An audience must attribute both a certain belief to the speaker and a certain meaning to his utterance in order to come up with an interpretation. For example, suppose a speaker utters, 'The cat is on the mat', in the presence of a cat being on a mat. If the audience judges the speaker to *mean* that the cat is on the mat, the audience will also most likely judge the speaker to *believe* that the cat is on the mat. While this may appear trivial, the triviality disappears once we think about other cases. Suppose the speaker utters, 'The cat is on the mat', in the presence only of a dog on the mat. In such a situation, the audience has two likely—but in fact many more—options to choose between: (1) the speaker means that the cat is on the mat and has a false belief, or (2) the speaker means that the dog is on the mat and has a correct belief. Either interpretation is possible. Which interpretation makes the most sense depends upon various features of the context: for example, the age, intelligence, eyesight, integrity and native language of the speaker. Interpretation (1) may be more plausible

if the speaker is very stupid or has poor eyesight. Interpretation (2) may be more plausible if the speaker is only 4 years old or is 40 years old but in the process of learning English. In the latter case, the speaker may think that 'cat' means 'dog' and thus use 'The cat is on the mat' to mean that the dog is on the mat.

In fact, the task of interpretation is even more complicated than Davidson has indicated. In addition to attributing beliefs to the speaker and a meaning to his or her utterance, the interpreter also needs to attribute a motive to the speaker, to determine the phonetic character to the utterance, and to judge his or her own cognitive capacities. For example, is the speaker intending to tell the truth, be deceptive, ironic, or humorous (motive)? Did the speaker utter the sentence 'She peaked in Stockholm' or 'She spoke in Stockton'? Did the audience really see a dog or was it a cat?

One upshot of the work of Quine and Davidson, is that it is a mistake to think of language as a complete and self-contained unit. Not only does speaking require other abilities, but in addition language itself is continuous with other intelligent behaviour. Linguistic behaviour is not a discrete segment of human behaviour. As Davidson says, 'we should realize that we have abandoned not only the ordinary notion of a language, but we have erased the boundary between knowing a language and knowing our way around in the world generally'.[12] One might speculate about the reason that people think of language as a well-defined entity. One suggestion is that when people are engaged in understanding what a speaker means, they often focus on the utterance itself and often think of the other aspects of the situation, such as the utterer's beliefs and intentions and the contextual facts, as merely background or collateral conditions. This is to say that utterances are salient; they jump out at the audience; nonetheless, the utterance itself is ultimately no more important to the interpretation than the other features just mentioned.

CONCLUSION

To study the philosophy of language is to see that there is progress in philosophy. The idea that the basic meaningful unit of language is the word was superseded by the idea that the basic unit is the sentence, and that was superseded by the twin ideas that the meaning of a sentence makes sense only as it relates to the language as a whole and that linguistic meaning ultimately rests upon people meaning things by their utterances. The idea that language is a discrete entity that can be understood independently of the non-linguistic context was superseded by the idea that language can be understood only in its context, and that idea was superseded by the idea that there is no sharp line to be drawn between linguistic behaviour and non-linguistic behaviour or between linguistic behaviour and the environment in which it occurs. Although there are no final answers, much has been learned in this century about the nature and uses of language, the primary locus of meaning, the nature of interpretation, the relation between language and empirical evidence, and the interrelation between meaning and the cognitive states of speakers.

NOTES

1 Hereafter, 'philosophers of language' refers *to* philosophers in the dominant tradition of Anglo-American philosophy in the twentieth century, unless otherwise indicated. An analogous remark holds for the term 'philosophy of language'.

2 A clear distinction between these three aspects of linguistic study was made at least as early as 1939 by Charles Morris [1.21], but we shall not follow his definitions exactly.

3 For another interpretation of Wittgenstein's view of picturing, see Canfield [1.6] and Wedin [1.30].

4 'Subject' and 'predicate' have been used in various ways by philosophers. In this article, the terms always refer to certain kinds of words or phrases. 'Subject' was sometimes used to refer to the topic of a sentence; that is, the

thing referred to by the *subject* in my sense. 'Predicate' was sometimes used to refer to what a predicate in my sense expresses, that is, a property or concept. Bertrand Russell often used these terms in various senses.

5 The noun phrase, 'present king of France', needs to be replaced with a non-noun phrase, such as the complex verb phrase 'is-male-and-monarchically-reigns-over-France', in order to forestall the following line of argument: Since 'the present king of France' is a noun, it must name something. What does it name? If the noun phrase is replaced by a verb phrase 'is-male-and-monarchically-…', no question arises about any seeming king of France.

6 'On Referring', in Strawson [1.28], 9.

7 In the remainder of this section, 'meaningful' means 'cognitively meaningful', as understood by the logical positivists.

8 'Smith's murderer' needs to be understood as a variation on 'the murderer of Smith'.

9 'Meaning and Reference', in Martinich [1.17], 287.

10 'A Puzzle about Belief', in Salmon and Soames [1.24], 122.

11 'Radical Interpretation', in Davidson [1.7], 134.

12 'A Nice Derangement of Epitaphs', in Grandy and Warner [1.11], 173.

CHAPTER 2
Formally oriented work in the philosophy of language

Nino B.Cocchiarella

One of the perennial issues in philosophy is the nature of the various relationships between language and reality, language and thought, and language and knowledge. Part of this issue is the question of the kind of methodology that is to be brought to bear on the study of these relationships. The methodology that we shall discuss here is based on a formally oriented approach to the philosophy of language, and specifically on the notion of a logically ideal language as the basis of a theory of meaning and a theory of knowledge.

THE NOTION OF A *CHARACTERISTICA UNIVERSALIS* AS A PHILOSOPHICAL LANGUAGE

The history of the formally oriented approach towards the philosophy of language goes back at least to René Descartes (1596–1650) and Gottfried Leibniz (1646–1716), and perhaps even further to the speculative grammarians of the twelfth century who believed that there was only one grammar underlying all of the natural languages of humanity (cp. Küng [2.28], 7). The speculative grammarians did not develop a formal methodology by which to study that grammar, however, because they believed that its structure was determined by the nature of things in the world and that the philosopher could discover that structure only by first considering the ontological nature of things. Descartes, the inventor/discoverer of analytic geometry and the idea of a *mathesis universalis,* also believed that underlying all speech there exists a *lingua universalis,* but what it represented was the form of human reason and not the nature of things in the world (cp. Cassirer [2.3], 1: 128). Descartes also did not attempt to construct or formalize such a language, beyond insisting that it must contain a *mathesis universalis,* because he thought that its construction must await the analysis of all the contents of consciousness into the simple ideas that were their ultimate constituents.

Leibniz agreed with Descartes that there exists a *lingua universalis* underlying all speech and that such a language represented the form of human reason. Leibniz was more programmatic in his approach, however. He called the general framework of such a philosophical language a *characteristica universalis,* and he attempted to formulate some fragments of the system. For Leibniz, a *characteristica universalis* was to serve three main purposes. The first was that of an international auxiliary language that would enable the people of different countries to speak and communicate with one another. Apparently, because Latin was no longer a 'living' language and new trade routes were opening up to lands with many different local languages, the possibility of such an international auxiliary language was widely considered and discussed in the seventeenth and eighteenth centuries (cf. Cohen [2.4] and Knowlson [2.27]). There were in fact a number of proposals and partial constructions of such a language during that period, but none of them succeeded in being used by more than a handful of people. It was only towards the end of the nineteenth century when Esperanto was constructed that such a language came to be used by as many as eight million

people. At present, however, the question of whether even Esperanto will succeed in fulfilling that purpose seems very much in doubt. Ido, another such language, which was constructed in 1907 by a committee of linguists, has not been used since about 1930 (cf. Van Themaat [2.46]).

The second and third purposes Leibniz set for his *characteristica universalis* are what distinguish it from its precursors and give his programme its formal or logistic methodology. The second purpose is that the universal character is to be based upon an *ars combinatoria,* i.e. an ideography or system of symbolization that would enable it to provide a logical analysis of all the actual and possible concepts that might arise in science. Such an *ars combinatoria* would contain both a theory of logical form, i.e. a theory of all the possible forms that a meaningful expression might have in such a language, and a theory of definitional forms, i.e. a theory of the operations whereby one could construct new concepts on the basis of already given concepts. The third purpose was that the universal character must contain a *calculus ratiocinator,* i.e. a complete system of deduction and valid argument forms, by which, through a study of the consequences, or implications, of what was already known, it could serve as an instrument of knowledge.

With a universal character that could serve these purposes, Leibniz thought that a unified encyclopedia of science could be developed throughout the world, and that, by its means, the universal character would then also amount to a *characteristica realis,* i.e. a representational system that would enable us to see into the inner nature of things and guide our reasoning about reality like an Ariadne's thread (cp. Cohen [2.4], 50). Thus, here in Leibniz's programme for a *characteristica universalis* we have an attempt to encompass the three relationships between language and reality, language and thought, and language and knowledge. In two fundamental parts of the programme, namely, the construction of an *ars combinatoria* and a *calculus ratiocinator,* we also have the critical components that are necessary for a formally oriented approach towards the philosophy of language.

THE NOTION OF A LOGICALLY PERFECT LANGUAGE AS A REGULATING IDEAL

The idea of a grammar underlying all natural languages is really not the same as the idea of an international auxiliary language, and both are different from the idea of a formal, artificial language containing an *ars combinatoria* and a *calculus ratiocinator* as a unified language of science. In the nineteenth century, with the rise of the new science and the development of a more abstract, algebraic notation in mathematics, interest became focused on the prospect of constructing a *calculus ratiocinator* as a formal system of logic that could be applied in different domains of discourse and independently of the vagaries of natural language. The mathematician George Boole (1815–64), for example, maintained that algebraic formulas could be used to express logical relations between propositions, or between concepts or classes, no less so than they can be used to express numerical relations between numbers. He showed in particular that there are structural analogies between the operations of multiplication and addition as applied to numbers and the operations of conjunction and disjunction as applied to propositions or concepts, as well as the operations of intersection and union as applied to classes. The result of developing such analogies as an abstract calculus is known today as Boolean algebra, a mathematical system that has provided a foundation for the development of computers as well as an algebraic basis for much of the formally oriented work in the philosophy of language.

Although the algebraic operations of Boolean logic are quite different from the grammatical rules of the categorical subject-predicate propositions of traditional syllogistic logic, it is significant that the latter can be explained in terms of the former. A traditional subject-predicate proposition of the form 'All *F* are *G*', for example, can be analysed in terms of the subordination of the concept *F* to the concept G, or the

inclusion of the class of things that are *F* in the class of things that are G (where inclusion is definable in terms of intersection as follows: . A subject-predicate proposition of the form 'Some *F* are *G*' can also be analysed in terms of the intersection of the class of things that are *F* with the class of things that are *G*, namely, as that intersection not being identical with the empty class (i.e. as , where 'o' represents the empty class). All categorical propositions and the entire system of traditional syllogistic logic can in this way be analysed and explained in terms of the algorithms of Boolean algebra. Boole himself believed that his calculus could be used 'to investigate the fundamental laws of those operations of the mind by which reasoning is performed' and that he could express those laws in the symbolic language of his calculus (Boole [2.2], chapter 1, section 1).

A different and more fundamental approach to the grammatical subject-predicate structure of natural language and to the idea of the laws of thought was taken by Gottlob Frege (1848–1925) in his book, *Concept-Script, A Formula Language for Pure Thought, Modeled upon that of Arithmetic*. What Frege did was utilize the newly developed function theory of arithmetic and mathematics to interpret a subject-predicate sentence of the form '*a* is *F*', where *'a'* stands for a singular term (e.g. a proper name or definite description), as the result of applying the concept *F,* now interpreted as a function (from objects to truth-values), to the argument *a,* i.e. as *F(a).* A subject-predicate-object sentence of the form *'a R b',* where *'a'* and *'b'* stand for singular terms and *'R'* for a transitive verb (such as, for example, the verb 'love' in *'a* loves *b'*) can then be interpreted as applying the relation *R,* now interpreted as a binary function (from objects to truth-values), to the arguments *a* and *b* (in that order), i.e. as *R(a,b).* In this way, Frege was able to formally represent and explain a more fundamental aspect of predication than is represented in Boolean algebra, namely, that in which we can express the relation between an object and a concept under which it falls, as well as provide a framework for the logic of relations in general.

Frege applied his function-argument analysis not only to these basic subject-predicate forms, moreover, but to those of the categorical propositions of traditional syllogistic logic as well. It was this analysis that introduced a new, and brilliant, insight into the structure of quantifier phrases of natural language, i.e. phrases beginning with such words as 'all', 'every', 'some', 'there is (are)'. Providing an adequate analysis of such phrases had been a major problem for medieval grammarians and logicians, and it was only with Frege's theory that the beginnings of a real solution were finally attained.

A quantifier phrase, according to Frege, stands for a (variable-indexed) second-level concept within which first-level concepts fall, which, in terms of his function-argument terminology, amounts to a function from first-level concepts (i.e. those that predicate phrases stand for) to truth-values. Thus, a sentence of the form 'Everything is *F* can be formally represented by , where stands for the secondlevel concept that 'everything' stands for (as indexed by the variable *'x*'). Similarly, 'Something is *F*' can be formally represented by , where stands for the second-level concept that 'something' stands for (as indexed by the variable *'x'*). A subject-predicate categorical proposition of the form 'All *F* are *G*' can then be equivalently interpreted as a sentence of the form 'Everything is such that if it is *F,* then it is *G*', which formally can be represented as , where ' ' is the symbolic counterpart of the (truth-functional) 'if-then' conditional phrase. Similarly, a categorical proposition of the form, 'Some *F* are *G*' can be equivalently interpreted as 'Something is both *F* and *G*', which formally can be represented as , where '&' is the symbolic counterpart of the 'both-and' conjunctive phrase; and a proposition of the form 'No *F* are *G*' can be symbolized either as or as , where '~' is the symbolic counterpart of the adverbial phrase 'it is not the case that'. Finally, and perhaps even more importantly, Frege's theory also accounts for quantifier phrases embedded within the scope of other quantifier phrases and explains the difference between, for example, 'Every man loves some woman', formally represented by ' *[F(x) [G(y) & R(x,y)]]',* and 'Some woman is loved by all men',

formally represented by , where *'F'* and *'G'* stand for the first-level concepts *being a man* and *being a woman,* respectively, and *'R'* stands for the first-level relation *loving*.

What is especially important about these kinds of formal analyses of the sentences of natural language is that they amount to a perspicuous logical representation of the truth-conditions determined by the content of those sentences, and, in that respect, they are readily amenable to the application of inference rules and allow for a rigorous analysis of the notions of logical deduction and formal validity. It was these features that led Frege to maintain that his concept-script was 'not a mere *calculus ratiocinator,* but a *lingua characteristics* in the Leibnizian sense' (Frege [2.20], 90). That is, Frege's goal was to construct 'a logically perfect language', and not just an abstract calculus, that could be used as the general framework for a language of mathematics and science. It was not designed to serve the purposes of ordinary or natural language, as an international auxiliary language might be, but rather was intended as a tool for the analysis of concepts and the formal development of mathematical and scientific theories. In this regard Frege maintained that the relation between his concept-script and ordinary or natural language was like that of the relation of the microscope to the eye. For even though the eye is superior to the microscope 'because of the range of its possible uses and the versatility with which it can adapt to the most diverse circumstances', nevertheless 'as soon as scientific goals demand great sharpness of resolution, the eye proves to be insufficient' (Frege [2.18], 6). That is, just as the microscope is a device 'perfectly suited' to the demand for great sharpness of visual resolution in science, so too Frege's concept-script is 'a device invented for certain scientific purposes, and one must not condemn it because it is not suited to others' (ibid.).

Another basic feature of Frege's function theory is the idea that the meaning of a complex expression is a function of the meanings of the component expressions that make it up, or what is generally called the compositionality law of meaning. Depending on what is meant by 'meaning', this law appears to be violated in natural language by contexts involving modal and intensional verbs, including in particular those used to ascribe knowledge, belief or desire (or what are generally called prepositional attitudes) to someone. This led Frege to distinguish between the sense *(Sinn)* and denotation *(Bedeutung)*—or what others call the intension and extension—of an expression, where by the sense of an expression he meant the mode by which it presents its denotation. The senses, or intensions, of 'the morning star' and 'the evening star', for example, are different even though their denotation, or extension, is the same (namely, the planet Venus). Frege called the sense of a sentence a thought *(Gedanke),* by which he meant a proposition (as an abstract object) and not a mental episode of thinking. The denotation, or extension, of a sentence he took to be a truth-value, i.e. either the true or the false. As applied to denotations (extensions), the compositionality law then stipulates that the denotation (extension) of a sentence (i.e. its truth-value) is a function of the denotations (extensions) of the expressions that make it up; and as applied to senses (intensions) the law stipulates that the sense (intension) of a sentence, i.e. the thought (proposition) it expresses, is a function of the senses of those same component expressions. Thus because 'the morning star' and 'the evening star' have the same denotation (namely, the planet Venus) but different senses, the sentences 'The morning star is not the evening star' and 'The morning star is not the morning star' have the same truth-value (namely, the false) as their denotations but express different thoughts as their senses.

In applying his doubly aspected notion of meaning to indirect discourse—i.e. to the kinds of linguistic contexts in which a sentential phrase occurs as the grammatical object of an intensional verb for a prepositional attitude—Frege maintained that the denotation of the embedded sentence is not the denotation it has in direct discourse but its sense instead. In this way we can consistently maintain the compositionality law for meaning, whether taken extensionally or intensionally, and also explain how we can ascribe to someone the (consistent) belief that the morning star is not the evening star without thereby also ascribing to that person the (inconsistent) belief that the morning star is not the morning star. For the truth-value

(denotation) of a sentence such as 'Ronald believes that the morning star is not the evening star' is then a function not of the denotation of 'The morning star is not the evening star'—which, as noted, is the same as the denotation of 'The morning star is not the morning star'—but of its sense instead, which is different from the sense of 'The morning star is not the morning star.'

THE THEORY OF LOGICAL TYPES

Although Frege laid the foundation for a theory of meaning with his distinction between the sense and denotation of expressions, he did not formally represent the distinction in his own concept-script or theory of logical form. His primary interest in developing his concept-script was to provide a logical foundation for arithmetic, and for that purpose he thought he needed only an extensional language, i.e. one for which the compositionality law could be restricted to extensions without any regard at all for senses or intensions (or those aspects of natural language, such as indirect discourse, that call for an intensional analysis).

Frege's insight about arithmetic was that the natural numbers are first and foremost the numbers we use in counting things. He was the first to see in this regard that the natural numbers are based ultimately on our use of numerical quantifier phrases to state that a certain number of objects fall under a given first-level concept. Thus, for example, in stating that there are 12 Apostles, or that there is i moon (of the earth), or that there are 9 planets (of the solar system), etc., we are in effect stating that the concepts *being an Apostle,* or *being a moon,* or *being a planet,* etc., have 12, or 1, or 9, etc., instances, respectively. Numerical concepts, in other words, are the second-level concepts corresponding to such quantifier phrases as 'There are *n* many objects *x* such that…*x*…', where '…*x*…' stands for a first-level concept.

The real philosophical problem about arithmetic, according to Frege, is to explain how conceptually we are able to move from numerical second-level concepts within which first-level concepts fall (i.e. from the concepts that numerical quantifier phrases stand for) to the natural numbers of arithmetic as denoted by numerals or other singular terms (i.e. to the natural numbers as objects that fall under first-level concepts), as represented in such statements as 'Two is a prime' and , as well as to such statements as 'The number of Apostles is 12', 'The number of moons is 1', and 'The number of planets is 9'.

It was for this purpose that Frege extended his concept-script to include a device for the representation of the extension of a concept (cf. Frege [2.19]). This device, which amounts to using the *spiritus lenis* (the comma sign over a letter) as a variable-binding abstraction operator, transforms an open sentential formula (i.e. a formula containing a free variable) into an abstract singular term that denotes the extension of the concept represented by that open formula. Thus, by applying the *spiritus lenis* to a symbolic formula *'F(x)',* we obtain the abstract singular term , which is taken to denote the extension of the concept *F,* i.e. the class of things that are *F*. (A comparable device in set theory is the use of braces and a colon to transform a formula *'F(x)'* into a singular term *'{x:F(x)}'*.)

It is noteworthy that the application of this device, according to Frege, amounts to a formal counterpart of the process of nominalization in natural language, i.e. the process whereby a (simple or complex) predicate expression could be transformed into an abstract singular term—but which, in ordinary language, is usually taken to denote the content (or intension) of the concept that the predicate expression stands for and not the extension of that concept. Thus, for instance, the simple predicate 'wise' (or the phrase 'is wise'), as used, for example, in 'Socrates is wise', can be nominalized and transformed into the abstract singular term 'wisdom' (or the gerund, 'being wise'), as used in 'Wisdom is a virtue' (or 'Being wise is a virtue'). Similarly, 'triangular' and 'equals' can be nominalized into 'triangularity' and 'equality' (or into 'being triangular' and 'being equal', as well as into a singular term beginning with an appositional phrase, such as 'the concept (of) being triangular' and 'the concept (of) being equal', etc.). In general, the process of

nominalization is effected in English through the use of gerunds and infinitive phrases, as well as the addition of such suffixes as '-ity' and '-ness'. This process, as we have said, transforms a predicate expression (which stands for a concept in the traditional sense of a universal as a predicable entity) into an abstract singular term, which in ordinary language is normally taken to denote the content (or intension) of the concept that the predicate otherwise stands for.

Frege's reason for interpreting a nominalized predicate as denoting the extension of the concept that the predicate otherwise stands for in its role as a predicate was primarily because he took his concept-script to be a strictly extensional language. Indeed, one of his basic laws of logic—namely (Vb), according to which the nominalizations of predicate expressions that stand for co-extensive concepts denote the same object—amounts to a principle of extensionality, which, formally, can be stated for monadic predicates as follows:

$$\forall x[F(x) \longleftrightarrow G(x)] \rightarrow \grave{x}\, F(x) = \grave{x}\, G(x).$$

Thus, because of his commitment to an extensional concept-script, there was no real point, according to Frege, to distinguish a predicate nominalization of the form 'the concept *F*' (i.e. as preceded by the appositional phrase 'the concept') from the somewhat longer abstract singular term of the form 'the extension of the concept *F*', the issue being one only of 'expediency' (cf. Frege [2.21], 106, and Cocchiarella [2.15], chapter 2).

It was by means of the nominalizing transformation of a predicate expression into an abstract singular term that Frege proposed to explain 'the miracle of number', i.e. the existence of numbers as objects, denoted by numerals and other singular terms, that are somehow derived from, or correlated with, the second-level concepts that numerical-quantifier phrases stand for. For in addition to correlating first-level concepts with their extensions as represented by such a transformation, Frege also correlated second-level concepts with first-level concepts, and, in effect, thereby correlated second-level concepts with the extensions of those first-level concepts—and it was these extensions as abstract objects that Frege took the natural numbers of arithmetic to be. In other words, by a double correlation of second-level concepts with first-level concepts and first-level concepts with their extensions, Frege showed how numbers as the second-level concepts that numerical-quantifier phrases stand for can be correlated with numbers as objects (cf. Cocchiarella [2.17], section 4).

Although we cannot go into the details of Frege's brilliant and insightful analysis of the natural numbers here, it is important to note how the notion of a hierarchy of concepts is implicit in that analysis— albeit a hierarchy that can be reflected downwards onto the level of objects through Frege's correlation of second-level concepts with first-level concepts and the latter with their extensions through a process corresponding to the nominalization of predicate phrases in natural language. It was this hierarchy, or reinterpretation of it, that became the basis of the theory of logical types that was developed later by Bertrand Russell (1872–1970) as a way to avoid Russell's famous paradox—a paradox that led to a contradiction in the extended version of Frege's concept-script.

Russell's paradox involves the very mechanism of nominalization that Frege represented in his concept-script by means of the smooth-breathing abstraction operator. For the paradox applies to an abstract singular term (such as 'the concept *F*') regardless whether that term is understood to denote the extension or the intension of a concept— where, by the intension of a concept, Russell (who took concepts to be intensional entities) understood just the concept itself. That is why Russell's paradox may be formulated either in terms of the class of those classes that are not members of themselves, or in terms of the concept of being a concept that does not fall under itself. Thus in regard to the concept of being a concept that does not fall under itself, Russell argued that either this concept falls under itself or it does not fall under itself; but if it falls under itself, then, by definition of that very concept itself, it does not fall under itself; and if it does not

fall under itself, then, again by definition, it does fall under itself, from which the contradiction that it both falls under itself and does not fall under itself follows.

Russell discovered his paradox some time around the turn of the century, and he then spent a number of years attempting a variety of solutions until he settled upon the doctrine of logical types. As described by Russell, this doctrine purports to set limits on what is meaningful or significant even in natural language, and for that reason, not without some justification, it has been strongly criticized. Nevertheless, in one form or another, the doctrine of logical types has been the mainstay of much of the formal work done in the philosophy of language—although today there are type-free alternatives, such as those developed by Cocchiarella (cf. Cocchiarella [2.15], chapter 2), that remain faithful to Frege's, and even Russell's, original insights.

As a source for insight into the logical structure of language, Russell's theory of logical types adds nothing new to what is already represented in Frege's concept-script. Both contain all the logical connectives for negation, conjunction, disjunction, etc., corresponding to the operations of Boolean algebra, and Russell adopted Frege's function theory for the elementary forms of predication—though, as noted, he did not interpret concepts extensionally as functions from objects to truth-values (the way Frege did) but rather intensionally as functions from objects to propositions, for which reason he also called concepts prepositional functions. Russell also recognized the importance of Frege's development of the logic of quantifiers, which, following Frege, he allowed to reach into the positions of predicate expressions as well as into the positions for singular terms—i.e. Russell followed Frege in allowing quantifiers to apply to expressions for functions as well as to expressions for arguments. Finally, Russell also followed Frege in allowing predicate expressions to be nominalized and occur as abstract singular terms—though instead of using Frege's smooth-breathing abstraction operator as a formal device for transforming a function-expression into an abstract singular term, Russell used his cap-notation, '^', as a variable-binding operator that transforms a function-expression (or open formula) *(x)* to an argument-expression, i.e. a singular term, . The main difference between them in this regard is that whereas for Frege such an abstract singular term denotes the extension of the concept represented by the open formula to which it is applied, Russell took it to denote the concept itself as a single entity. Accordingly, in respect to these factors—namely, (1) basic logical forms of predication (as represented by the function-argument notation), (2) prepositional connectives (corresponding to the operations of Boolean algebra), (3) quantifiers that reach into predicate as well as subject (or argument) positions and (4) a device for nominalizing (complex or simple) predicate expressions and transforming them into abstract singular terms— Russell really did not add any new insights to the essentials of what constitutes a theory of logical form according to Frege.

What Russell did do, as a way to avoid his paradox, was divide the predicate expressions (and their corresponding abstract singular terms) of Frege's second-order logic with nominalized predicates as abstract singular terms into a hierarchy of different types, and then he imposed the grammatical constraint that nominalized predicates can occur as argument- or subject-expressions only of predicates of higher types —thereby ruling out as grammatically meaningless an expression of the form , as well as its negation, , which purports to indicate that the concept denoted by does not fall under itself, which is just the kind of expression needed to generate Russell's paradox. (Note: Russell's division of predicates actually involves two hierarchies, one a 'vertical' hierarchy corresponding to Frege's levels of concepts, and the other a 'horizontal' hierarchy corresponding to a ramification of all the concepts on a given level. The *simple* theory of types, which is all that is needed to avoid Russell's paradox, represents only the first hierarchy, whereas the *ramified* theory of types represents both.)

These grammatical constraints are undesirable, it should be emphasized, because they exclude as meaningless many expressions that are not only grammatically correct in natural language but also

intuitively meaningful (and that sometimes even result in true sentences). Fortunately, it turns out, the logical insights behind these constraints can be retained without imposing the constraints as conditions of grammatical correctness. In fact, as shown by Cocchiarella, those logical insights can be retained—and Russell's paradox avoided—in a type-free second-order logic with nominalized predicates as abstract singular terms of essentially just the sort originally conceived by Frege (cp. Cocchiarella [2.15], chapter 2).

RADICAL EMPIRICISM AND THE LOGICAL CONSTRUCTION OF THE WORLD

Russell took his theory of types to be the framework of 'a logically perfect language', by which he meant a language that would show at a glance the logical structure of the facts that are described by its means (cp. Russell [2.35]). Such a language, according to Russell, 'would be one in which everything that we might wish to say in the way of propositions that are intelligible to us, could be said, and in which, further, structure would always be made explicit' (Russell [2.36], 165). All that needs to be added to the theory of logical types to be such a language, Russell maintained, is a vocabulary of (non-logical) descriptive constants that correspond to the meaningful words and phrases of natural science and ordinary language (Russell [2.35], 58ff.). The constants of pure mathematics, unlike those of the natural sciences, do not need to be added to the framework because they, according to Russell, are all definable in purely logical terms within the framework itself. Knowledge of pure mathematics is explainable, in other words, as logical knowledge—a view known as logicism—and, in particular, as knowledge of the propositions that are provable in the theory of logical types independently of any vocabulary of descriptive constants.

Despite his logicism regarding mathematics, Russell was a radical empiricist as far as our knowledge of physical or concrete existence was concerned. All our empirical knowledge of the world, he maintained, must be reducible to our knowledge of what is given in experience, by which he meant that it must be constructible within the framework of the theory of logical types from the lowest level of objects, which he assumed to be events corresponding to our sensory experience. It was by means of logical constructions within this framework that Russell proposed to bridge the gulf between the world of physical science and the world of sense, and he was guided in this regard by 'the maxim which inspires all scientific philosophizing, namely "Ockham's razor": *Entities are not to be multiplied without necessity*. In other words, in dealing with any subject-matter, find out what entities are undeniably involved, and state everything in terms of these entities' (Russell [2.34], 112). Thus, because sense data are the entities that are 'undeniably involved' in all of our empirical knowledge according to Russell, 'the only justification possible' for such knowledge 'must be one which exhibits matter as a logical construction from sense-data' (ibid., 106).

Though Russell gave a number of examples of how such a construction might be given, it was Rudolf Carnap (1891–1970) who, using nothing more than the framework of the simple theory of logical types (and a certain amount of empirical science, such as gestalt psychology, about the structure of experience), gave the most detailed analysis indicating how we might reconstruct all our knowledge of the world in terms of what is given in experience (cp. Carnap [2.5]). This meant in particular that all the concepts of science could be analysed and reduced to certain basic concepts that apply to the content of what is given in experience. One of the important patterns for such an analysis is known today as *definition by abstraction,* whereby, relative to a given equivalence relation (i.e. a relation that is reflexive, symmetric and transitive), certain concepts are identified with (or represented by) the equivalence classes that are generated by that equivalence relation. This pattern was used by Frege and Russell in the analysis of the natural numbers (as based on the equivalence relation of equinumerosity, or one-one correspondence), and was then used again in the analysis of the negative and positive integers, the rational numbers, the real numbers and even the imaginary numbers. Carnap, who took definition by abstraction as indicative of the 'proper analysis' of a concept,

generalized the pattern into a form that he called ‘quasi analysis’ (but which, he acknowledged, really amounted to a form of synthesis), which could be based on relations of partial similarity instead of full similarity, i.e. on relations that amount to something less than an equivalence relation. The concepts definable in terms of a quasi-analysis specify in what respect things (especially items of experience) that stand to one another in a relation of partial similarity agree, i.e. the respect in which they are in part, but not fully, similar (cp. Carnap [2.5], sections 71–4). In this way Carnap was able to define the various sense modalities (as classes of qualities that intuitively belong to the same sense modality, where concepts for sense qualities are definable in terms of a partial similarity between elementary experiences), including in particular the visual sense and colour concepts (as determined by the three-dimensional ordering relation of the colour solid).

Using the various sense modalities, Carnap went on to construct the four-dimensional space-time world of perceptual objects, which, with all its various sense qualities, ‘has only provisional validity’, and which, for that reason, ‘must give way to the strictly unambiguous but completely quality-free world of physics’ (Carnap [2.5], 207). We cannot go into the details of Carnap’s ‘constructional definitions’ here, but we should note that all that Carnap meant by a logical analysis by means of such definitions was translatability into his constructional language—i.e. into an applied form of the simple theory of logical types as based on a primitive descriptive constant for a certain relation of partial similarity between elementary experiences. Such a translation need not, and in general did not, preserve synonymy, nor did it in any sense amount to an ontological reduction of ordinary physical objects to the sensory objects of experience. What it did preserve, according to Carnap, was a material equivalence (i.e. an equivalence of truth-value) between the sentences of ordinary language, or of a scientific theory, and the sentences of the constructional language. (Note: the same claim is made in Goodman [2.22] for an alternative constructional language based on nominalist principles that are opposed to the predicate quantifiers of type theory.)

THE LOGICAL EMPIRICIST THEORY OF MEANING

Carnap was a founding member of the Vienna Circle, a group of philosophers and scientists who, following Leibniz, sought to unify all the different sciences within a common linguistic framework based on modern symbolic logic (which, for them, meant the theory of logical types). The primary method of the Circle was logical analysis, which they took to involve the task of specifying the meaning of all scientific statements and concepts in a precise way and of thereby excluding as meaningless all the statements of traditional metaphysics. Metaphysical theories, they claimed, were too narrowly tied to ordinary, natural language, which uses the substantive not only for things, but for qualities, relations, processes, etc., as well, and thereby ‘misleads one into a thing-like conception of functional concepts’ (Hahn, Neurath and Carnap [2.24], 9). Curiously, they did not seem to realize (at least initially) that the theory of logical types itself formally incorporates a ‘thing-like conception of functional concepts’ through its incorporation of a device for nominalization (such as Russell’s cap-operator), thereby allowing expressions for prepositional functions to be nominalized and occur as argument- or subject-expressions of expressions for yet higher-order types of prepositional functions. Indeed, the reduction of mathematics to logic, which was a central part of their view, is not possible without some such device corresponding to the process of nominalization of predicate expressions in natural language (cp. Cocchiarella [2.15], chapter 5).

Carnap and other members of the Vienna Circle adopted what is sometimes called *the linguistic doctrine of the a priori,* according to which a declarative sentence can be known to be true (or false) *a priori* if, and only if, the sentence is analytically true (or false, respectively). Here, by analytic truth (or falsehood) they meant truth (or falsehood) by linguistic convention, i.e. in virtue of the meanings of the words that make up

the sentence. This doctrine amounts to a linguistic theory of the *a priori* and is intended as logical empiricism's answer to the Kantian question of how there can be *a priori* knowledge. Logic and mathematics are knowable *a priori,* according to such logical empiricists, because all logical and mathematical truths are analytic truths.

A basic principle of empiricism is that what is true, but not analytically true, is knowable only on the basis of experience. This led to a logical empiricist theory of meaning, according to which a (declarative) sentence is cognitively meaningful (in the sense that it can be said to be true or false) if, and only if, either it is analytically true or false, or its truth or falsity is capable of being tested by experiential evidence (cp. Hempel [2.25], [2.26]). Initially, the idea of being capable of being tested by experiential evidence was explained by early logical empiricists in terms of the notion of complete verification in principle, and for that reason their theory came to be called *the verifiability theory of meaning*. On this account, a declarative sentence is said to be empirically meaningful if, and only if, it is not analytic and follows logically from some finite, logically consistent class of observation sentences—where by an observation sentence is meant a sentence that asserts or denies that an object (or group of objects) has some particular observable characteristic. (The finitude of the class means that complete verification is possible after a finite number of observations.) This explanation fails for sentences of the form 'All *F* are *G*', however, even where *'F'* and *'G'* stand for observable characteristics—unless it is already empirically knowable that the number of things that are *F*'s is finite. Such a sentence is completely falsifiable, however, by simply observing one thing that is *F* but not G, and, for that reason, one might consider redefining empirical meaning in terms of complete falsifiability in principle instead. But then, by the same argument, negations of sentences of the form 'All *F* are *G*' would not be empirically meaningful. Other attempts to explicate the idea of empirical meaning also failed for similar reasons. (Not everyone agrees that all these attempts have failed, however; for example, see Rynin [2.37].)

One of the more interesting proposals in this direction involves the notion of a logically correct empiricist language, by which, generally, was meant an applied form of the simple theory of types. The only (non-logical) descriptive constants of such a theory would be those that stand for observable characteristics of things, i.e. so-called observation predicates, where by an observable characteristic was meant an observable property of ordinary macro-physical objects and not the kind of characteristic that applies only to sense data. Such an empiricist language would involve only perspicuous logical forms by which the truth-conditions of any of its sentences could be determined in an exact way, and, in addition, it would embody the linguistic theory of the *a priori,* i.e. the doctrine that all and only analytically true (false) sentences can be known to be true (false) *a priori*. An additional constraint was that the language must be extensional (i.e. that Frege's compositionality principle must be valid when restricted to the extensions of expressions), which meant that the language could include no intensional operators (such as that for necessity) or counterparts of intensional verbs. A (declarative) sentence of natural language, or of a scientific theory, was then said to be cognitively meaningful if, and only if, it is translatable (preserving only material equivalence) into such a logically correct empiricist language.

The idea of such a proposal is that a logically correct empiricist language would give us control over vocabulary (by excluding nonsensical words) as well as over logical syntax, i.e. logical grammar and validity. In this regard the proposal is like Leibniz's programme for a *characteristica universalis,* except that Leibniz did not accept the empiricist principle that all concepts must be analysable in terms of the observable characteristics of things. Thus, on the proposal as initially formulated, a predicate expression of natural language will be empirically meaningful if, and only if, a formal, symbolic counterpart of it is definable in terms of the observation predicates of a logically correct empiricist language, and therefore, because both a sentence of the form 'All *F* are *G*' and its negation, where *'F'* and *'G'*, are definable in the

language in terms of observation predicates, are well formed in such a language, they will both be taken as empirically meaningful (thereby by-passing the problem of restricting ourselves to a finite number of observations).

The trouble with this proposal is that it is still too restrictive; for there are too many predicate expressions of both scientific and ordinary discourse that are clearly meaningful to us but that cannot be explicitly defined in terms of observation predicates. In particular, predicate expressions that stand for dispositions, or powers, or capacities, or tendencies, etc., cannot be defined in such a language unless we were to add to it, for instance, modal operators for causal necessity (or possibility) by which law-like counter-factual conditionals might be formulated. Such operators, however, generate non-extensional contexts and violate the restriction to an extensional language that logical empiricism demands. For this reason, Carnap suggested that the original proposal be modified so that dispositional predicates could be introduced into a logically correct empiricist language by a pattern of quasi-definitions (which he called *reduction sentences*) that get at some of the content of counter-factual conditionals but without requiring the introduction of intensional operators (cf. Carnap [2.7]). This way of extending a logically correct empiricist language vastly extends the range of significance it gives to the sentences of ordinary and scientific discourse, but, unfortunately, it still fails to account for most of the theoretical predicates of modern science that have to do with the micro-physical world—not to mention the intensional verbs of natural language that stand for the various prepositional attitudes that are studied in cognitive science. Some attempts were made to overcome these problems (see Carnap [2.11] and [2.12] for his later analyses of theoretical predicates), but, at least in the case of the intensional verbs of natural language, they have not in general succeeded.

SEMIOTIC AND THE TRINITY OF SYNTAX, SEMANTICS AND PRAGMATICS

In time Carnap did come to think that an explication of logical necessity could be given, but this involved a new kind of approach to language, namely, a semantical approach. Earlier, in Carnap [2.6], he had adapted certain metamathematical techniques and ideas of the mathematician David Hilbert (1862–1943) that he applied to the general analysis of the syntax of formal languages. In that work Carnap distinguished between the formal language whose logical syntax we want to study, which he called an *object-language,* and the language in which we carry out that study, which he called the *meta-language.* Originally, the latter was a *syntactical* metalanguage because it dealt only with the syntactical aspects of the object-language, such as its rules of formation (defining the well-formed expressions of the different logico-grammatical categories of the language) and its rules of transformation (defining the conditions under which sentences follow validly from other sentences of the language). On his later approach, however, Carnap extended the meta-language to include expressions that stand for semantical relations, such as the various *designation* relations that hold between the expressions of an object-language and the entities they stand for or designate. The primary goal of such a meta-language is to define the semantic notions of truth and falsehood—and the notions of logical truth and falsehood as well—as applied to the sentences of the object-language. The meaning of a sentence of such a language was then to be given in terms of its truth-conditions, i.e. the conditions under which the sentence can be said to be true or false, respectively (cp. Carnap [2.8], section 7).

The idea that the meaning of a sentence is its truth-conditions was emphasized earlier by Ludwig Wittgenstein (1889–1951) in his *Tractatus Logico-Philosophicus* ([2.47], 4.024, 4.46), which describes a metaphysical framework known as logical atomism. The elements of logical atomism are atomic states of affairs, each of which is logically independent of the rest, and the totality of which make up logical space. Different possible worlds, including the actual world, consist of all the atomic states of affairs that obtain in those worlds. It was essentially this framework that Carnap adopted in developing his semantics for logical

necessity. For by associating an atomic sentence with each atomic state of affairs, the different possible worlds could be described in terms of certain classes of atomic sentences, or their negations, that Carnap called *state descriptions*. That is, a state description for the formal object-language is a class of atomic sentences, or their negations, such that for every atomic sentence of the language either it or its negation, but not both, is in the class. Truth in a possible world is then definable for all the sentences of the language in terms of the atomic sentences, or their negations, that are in the state description corresponding to that possible world; and logical truth is definable as truth in every logically possible world.

With the notion of a logically possible world at hand, Carnap realized, we are able to define the truth-conditions for sentences of the form 'It is (logically) necessary that…' (where '…' stands for a sentential clause) in terms of a strictly extensional meta-language. In this way, Carnap maintained, we may give up the thesis of extensionality for the object-language while retaining it for the meta-language, which is now the language that is of primary importance for philosophy. Thus, where is a sentential operator corresponding to the phrase 'it is (logically) necessary that', Carnap's criterion for the truth-conditions (and thereby the meaning) of an object-language sentence of the form is that is to be true (in a possible world) if, and only if, is logically true (i.e. if, and only if, is true in all logically possible worlds) (cf. Carnap [2.9]). (For a fuller discussion of how logical atomism provides a paradigmatic semantics for logical necessity, see Cocchiarella [2.15], chapters 6 and 7.)

The idea of an extensional semantical meta-language in which the notion of semantic truth (and falsehood) can be defined for the sentences of a formal object-language was also the goal, in the early 1930s, of a number of Polish logicians, including especially Alfred Tarski (1902–83). Tarski succeeded in defining such a notion in terms of what today is called *model theory,* where by a model is meant a set-theoretic construction that amounts to a counterpart to the notion of a possible world (cp. Tarski [2.43] and [2.42]). The language of set theory (which is an extensional language *par excellence*) has today become the principal framework within which most of the work of model theory and formal semantics is carried out, and different kinds of model-theoretic constructions have been used to give the truth-conditions for a variety of modal operators in addition to that for logical necessity, and even for some operators that stand for prepositional attitudes as well. As a branch of set theory, in other words, model theory has been developed and applied not just to a number of extensional mathematical languages but to intensional fragments of natural language as well (cp. Addison, Henkin and Tarski [2.1]; Partee, ter Meulen and Wall [2.32]). It should be emphasized, however, that set theory, the general framework within which model theory has been developed, is primarily a mathematical framework, and in that regard the language of set theory is not a *lingua philosophica* in the sense originally intended by Leibniz, or as later developed by Frege, Russell, Carnap and others. (See Cocchiarella [2.16] for a more detailed discussion of this issue, and especially of the conceptual priority of a formal theory of predication over a formal theory of membership in a set or class.)

In addition to syntax (which studies the logico-grammatical rules of formation and transformation of an object-language) and semantics (which studies the different designation relations between the well-formed expressions of an object-language and the entities designated by those expressions, including especially the truth-conditions of the sentences of that object-language), there are also relations between the expressions of an object-language and the contexts in which those expressions are used, including especially the people who use the language in those contexts. The study of these kinds of relations is generally called *pragmatics,* and all three kinds of study together, i.e. syntax, semantics and pragmatics, is called *semiotic* (cp. Morris [2.30]). For Carnap, it should be noted, there can be only an empirical or descriptive pragmatics and not a pure (or analytic) pragmatics the way there can be a pure logical syntax and a pure logical semantics. This is because for Carnap the relation of designation in pragmatics is a psychological concept, and psychology is

an empirical, descriptive science and not an analytic science. Thus, because the task for philosophy now is semiotical analysis (and not just syntactical or semantical analysis), the proper framework for philosophy, according to Carnap, is no longer pure, logical syntax (as Carnap had assumed it to be in 1936)—i.e. it is no longer a pure syntactical meta-language in which our goal is to study the logical syntax of different object languages— nor is it a pure logical semantics—that is, a pure, semantical metalanguage by which we can study the notions of truth and logical truth and the relation of designation in general. Rather, the proper framework for philosophy now is one in which we can study 'the semiotical structure of the language of science, including the theoretical part of everyday language'. It is a framework in which we can engage not only in logical analysis (as part of pure semantics if meanings are involved, or as part of pure logical syntax if the analysis is purely formal) but also in the analysis of the problems of gaining and communicating knowledge, which, according to Carnap ([2.8], 250), properly belongs to pragmatics.

PRAGMATICS FROM A LOGICAL POINT OF VIEW

The shift to pragmatics, i.e. to a study of the contexts of use of ordinary, natural language, was already made by some logical empiricists. Otto Neurath (1882–1945), for example, maintained that although the unification of scientific language is one of the goals of the movement, nevertheless 'one must test all theories by means of the language of daily life', and that, in particular, one must systematically analyse the 'correlations between the calculus of theories and the language of daily life' (Neurath [2.31], 19). Neurath, however, did not himself make any investigations of how 'the language of daily life' could be systematically correlated with the formal, ideal language of logical empiricism that would serve as a unified language for science. Indeed, instead of studying those correlations, a new generation of philosophers of language rejected the formal language approach altogether and insisted on studying only the functioning of ordinary language in daily life as an alternative to the formally oriented approach (cf. Wittgenstein [2.48]). It was argued, for example, that 'the concepts used in non-scientific kinds of discourse could not literally be *replaced* by scientific concepts serving just the same purposes; that the language of science could not in this way *supplant* the language of the drawing-room, the kitchen, the law courts and the novel' (Strawson [2.40], 505).

It is noteworthy that the response of the formally oriented philosophers of language to this sort of criticism was not to ignore ordinary language but to turn to a formal analysis of its various context-dependent features. One feature in particular that was taken as an object of study was the use of tenses to distinguish our references to events in the past, the present and the future in any given context of use of language. Arthur Prior (1914–69) suggested that this contextual feature of our speech acts could be formally represented by tense operators, such as and , corresponding to the adverbial phrases 'it was the case that' and 'it will be the case that', respectively. (The simple present tense was assumed to be built into the form of an atomic formula, which could then be modified by the application of the past- and future-tense operators.) By means of these operators, formal counterparts for the adverbial phrases 'it always was the case that' and 'it always will be the case that' are definable as, and , respectively (where '~', as already noted, is the negation sign and represents the adverbial phrase 'it is not the case that'). As is indicated in Prior [2.33], different tense logics, corresponding to our different conceptions of the structure of time, can be formulated in terms of these tense operators.

Some examples of laws of tense logic are () and (), corresponding to the theses that if a sentence is (now) the case, then it always was the case that it was (then) going to be the case, and it always will be the case that it was the case (prior to then). Similarly, () and (), with iterated applications of the same tense operators, represent the theses that what had been the case (prior to some time in the past) simply was the

case, and what will be the case relative to some future time simply will be the case. (Note that represents the past-perfect tense of English and that represents the future-perfect tense.) The assumption that the structure of time in the past is dense (i.e. that between any two past moments there is another past moment) is represented by ( ); and that it is dense in the future as well is represented by (). The following two laws (where 'V' represents inclusive disjunction), defended by Cocchiarella in his tense logic but rejected by Prior (cf. Prior [2.33], chapter 3, section 6), assume that events in the past (or future, respectively) of the local time of any context are connected (i.e. that they either occurred at the same time or that one preceded the other):

$$\mathscr{P}\phi \,\&\, \mathscr{P}\psi \rightarrow \mathscr{P}(\phi \,\&\, \psi) \vee \mathscr{P}(\phi \,\&\, \mathscr{P}\psi) \vee \mathscr{P}(\psi \,\&\, \mathscr{P}\phi)$$
$$\mathscr{F}\phi \,\&\, \mathscr{F}\psi \rightarrow \mathscr{F}(\phi \,\&\, \psi) \vee \mathscr{F}(\phi \,\&\, \mathscr{F}\psi) \vee \mathscr{F}(\psi \,\&\, \mathscr{F}\phi).$$

Arthur Prior formulated a number of different tense logics, as we have said, corresponding to different conceptions of the structure of time. He applied those logics to different philosophical theses, including in particular J.M.E.McTaggart's argument against the reality of time (cf. Prior [2.33], chapter 1). Prior had no doubts about the reality of time in the present (with a past whose ontological status is now settled), but he did have his doubts about the reality of the future and the meaning of future contingent statements (as they occur, for instance, in Aristotle's famous sea-battle argument), and some of his logics make important formal contributions of different ways to represent the openness (or coming yet to be) of the future. Prior also showed how certain views of antiquity about the temporal nature of necessity—namely, Diodorus' view that what is possible is what is or will be the case, and Aristotle's view that what is necessary is what always has been, is and always will be the case—can be formally represented in tense logic.

In addition to doubts about the ontological status of the future, Prior also maintained that reference to past and future objects is meaningful only in so far as such reference (as it is represented by existential quantifier phrases, , , etc.) occurs within the context of the past and future tense operators. It should be emphasized that the issue here is not with the truth of statements about past or future objects but with the meaningfulness of those statements. The sentence 'There did exist someone before whom no one else existed', for example, is clearly meaningful and can be formally represented by ' ', where the reference to a past person (with the predicate *'H'* representing the verb phrase 'is a person') is within the scope of the past-tense operator. In this way an ontological commitment to a past person before whom no other person existed is said to be at best only indirect and weaker than a commitment in which an existential quantifier phrase applies to the time of the context of use and does not occur within the scope of a tense operator (where it would apply to a past or future time).

This solution does not work for sentences such as 'There did exist someone who is an ancestor of everyone now existing', however, which are also clearly meaningful (regardless whether or not they are also true). In this sentence the quantifier phrase 'everyone now existing', which refers only to people existing at the moment of speech, is within the scope of (or dominated by) the first quantifier phrase, 'there did exist someone', which refers to a past person who does not (or at least who may not) exist at the moment of speech. The formula' ', where *'R'* stands for the ancestor relation, will not do as an analysis because it represents the different English sentence, 'There did exist someone who was an ancestor of everyone *then* existing'; and the formula ' ' will not do because it represents the different English sentence, 'Everyone now existing had an ancestor', with the order of dominance between the two quantifier phrases reversed. What this shows is that direct quantification over past objects (and over future objects as well), which is something that we commonly do in natural language, cannot be accounted for by indirect forms of quantification, i.e. by quantifier phrases occurring only within the scope of the past (or future) tense operator. Some other sort of formal device is needed —e.g. primitive quantifiers that refer directly to past (or future) objects, or a *now*-operator that semantically relates formulas occurring within the scope of a

tense operator to the moment of speech (and perhaps a *then*-operator as well that relates embedded formulas to a past, or future, moment of reference)—in order to adequately represent these kinds of sentences of natural language (cp. Cocchiarella [2.14]). In that case, however, the nature of our ontological commitment to past (and future) objects cannot be as narrowly interpreted as Prior has maintained that it should be.

Tense logic was not the only subject in which pragmatics was formally studied. In the 1960s Richard M. Montague (1932–71) made important contributions and advances in this area. Montague showed, for example, how truth-conditions can be defined for pragmatic operators in general, including symbols for demonstrative and personal pronouns, once we replace the notion of a possible world (or model) by the notion of a context of use (or what Montague also called an *index* or *point of reference*). The set-theoretic representation of a context of use need not deal with all the complexities of a real context, but only with those aspects that are relevant to the linguistic expressions in question—such as, for example, the local time of the context (for the truth-conditions of the tense operators), who is speaking (as the referent the first-person pronouns), who is being spoken to (as the referent of the second-person personal pronouns), the objects that are indicated by the speaker (as the referents of demonstrative pronouns), etc.

Montague showed that even though the truth-value (or extension) of a sentence in a given context of use (or point of reference) is not in general a simple recursive function of the extensions of the component expressions of that sentence in that context (or at least not in the case of sentences containing pragmatic operators that shift the point of reference, as do the tense operators), nevertheless the intension of the sentence is a recursive function of the intensions of its parts. Thus, because the intension of an expression will determine its extension at a given point of reference, a recursive definition of truth for the formulas of a formal pragmatic language is available in terms of the intensions of those formulas and their parts. Following Carnap [2.10], Montague represented the intension of an expression of a given type as a function from the possible contexts of use (or indices, or points of reference) to the extensions that the expression has in those contexts (cp. Montague [2.29], chapters 3 and 4). Thus, for instance, the intension of an individual constant (as the formal counterpart of a proper name) is a function from the different possible contexts of use (i.e. the contexts in which that name might be used) to the objects (i.e. extensions, if any) denoted by that individual constant; and the intension of an n-place predicate constant is a function from the different possible contexts of use to the classes of n-tuples of objects that are the extensions of that predicate in those contexts. Montague called the first kind of intension an *individual concept* and the second an n-ary *relation-in-intension,* or, where n=1, a *property*. The intension of a declarative sentence, which Montague called a *proposition,* was then represented as a function from possible contexts of use to truth-values (the Fregean extensions of sentences).

By means of this way of representing intensions, Montague was able to give a formal, set-theoretic definition of the semantic notion of truth in a context of use (or at an index or point of reference) of the sentences of a formal pragmatic language, and in terms of that notion he was then able to define the related semantic notions of *logical truth* and *logical consequence* in the sense of general pragmatics. In this way, the logic of general pragmatics became a part of pure, logical semantics.

INTENSIONAL LOGIC

Pragmatic operators, on Montague's approach, amount to higher-order properties and relations (in intension) of propositions, which means that pragmatic operators can be represented by the higher-order predicates of an intensionalized type theory—e.g. a type theory in which a modal operator for necessity has been added. Such a higher-order logic is generally what is meant by intensional logic, and it gives further justification for the claim that pragmatics is part of semantics. Montague himself formulated two such

intensional logics, one corresponding to a Russellian perspective in which the intension-extension (or sense-denotation) distinction is not fundamental, and the other corresponding to a Fregean perspective in which it is. It is the latter that came to be of central importance in what is now called Montague grammar.

Montague applied his first intensional logic to a variety of philosophical puzzles, including in particular the analysis of such entities as pains, events, tasks and obligations (cf. Montague [2.29], chapter 5). Sentences in which we purport to speak of such entities 'play a conspicuous role in philosophy, perceptual psychology, and everyday discourse', Montague observed, and 'it therefore appears desirable to investigate the nature of the entities in question, construct an exact and convenient language in which to speak of them, and analyze the pertinent notion of logical consequence' (ibid., 148). Tasks, for example, are taken by Montague to be certain two-place relations-in-intension between persons and moments, so that by the performance of a task *R* by a person *x* at a moment *t* we are taken to mean that *x* stands in the relation *R* to *t*, i.e. *R(x,t)*. Pains, and experiences in general are then taken be of the same ontological sort as tasks. Thus, for instance, 'the experience of seeing a tree is the relation-in-intension born *by x to t* just in case *x* sees a tree at *t*' (ibid., 151), and therefore for *x* to have the experience *R* at *t* is for *x* to bear the relation-in-intension *R* to *t,* i.e. *R(x,t)*. Similarly, for a person *x* to discharge or fulfil an obligation *R* at a moment *t* is just for *x* to bear the relation-in-intension *R* to *t*.

The point of the reduction of such 'dubious ontological categories' as pains, tasks and obligations to relations-in-intension, according to Montague, is that it enables us to have 'an exact language capable of naturally accommodating discourse about the dubious entities'— namely, the language of intensional logic —and therefore a language for which we have 'an intuitively satisfactory notion of logical consequence' by which we can resolve a variety of philosophical puzzles or paradoxes purportedly regarding such entities (ibid., 154). One such puzzle, for example, concerns the analysis of a sentence such as 'Jones sees a unicorn having the same height as a table actually before him', which, because it involves a visual experience of a relation between something that does not exist and something that does, has been taken by some philosophers as implying the existence of sense data (some of which are indicative of an existent object and others of which are not). On Montague's analysis, the truth of the sentence does not imply either that a unicorn exists or that sense data purportedly indicative of a unicorn exist.

In his analysis of this sentence, Montague distinguished a veridical from a non-veridical sense of 'sees' and paraphrased the latter as 'seems to see', which he analysed in terms of a relation between a person and a property (such as the property of seeing a unicorn) that the person seems to (but might not really) have. Thus, for the non-veridical sense of 'sees', Montague paraphrased 'Jones sees a unicorn' as 'Jones seems to see a unicorn', which, in terms of the relation of seeming-to-have (a property), can be formally represented as 'Seems(Jones, to see a unicorn)'. Here, the property Jones seems to (but need not really) have is denoted by the infinitive phrase 'to see a unicorn', which is the result of nominalizing the complex predicate 'see(s) a unicorn'.

As nominalized predicates, infinitive phrases can be formally represented as abstract singular terms, which means that in the case of a complex predicate phrase (such as 'see(s) a unicorn') we need a formal, variable-binding device, such as Frege's or Russell's, whereby the predicate phrase can be nominalized and transformed into an abstract singular term. Montague did not use either Frege's or Russell's devices, however, but adopted instead (at least in his later work) Alonzo Church's -operator to represent complex predicates, which, by deleting the parentheses that are formally part of a predicate, he then also used to represent the abstract singular terms that result when those complex predicates are nominalized. Thus, whereas '[*y* (Unicorn*(z)* & Sees(y,z))]( )', with the accompanying pair of parentheses for argument-expressions, represents the complex predicate phrase 'is a *y* such that *y* sees a unicorn' (where 'sees' is used in its veridical sense), the related expression '[*y* (Unicorn*(z)* & Sees*(y,z)*)]', without the accompanying pair

of parentheses, is not a predicate but an abstract singular term that represents the infinitive phrase 'to be a *y* such that *y* sees a unicorn', or, more simply, the infinitive phrase 'to see a unicorn'.

The sentence 'Jones seems to see a unicorn' can now be formally represented as 'Seems(Jones, [*y* (Unicorn*(z)* & Sees*(y,z)*)])', which, as indicated above, implies the existence neither of a unicorn nor of sense data (veridical or otherwise) indicative of a unicorn. Similarly, the sentence 'Jones sees a unicorn having the same height as a table actually before him', with 'sees' taken in its non-veridical sense, can now be formally analysed as [Table*(x)* & Before(*x*,Jones) & Seems(Jones, [*y* (Unicorn(z) & Sees*(y,z)* & Has-the-same-Height-as*(z,x)*)])], which also implies neither the existence of a unicorn nor of sense data (veridical or otherwise) indicative of a unicorn.

This kind of analysis, it should be emphasized, depends essentially on the use of circumlocution and paraphrase, which in the end Montague found unsatisfactory. This is especially so in the case of intensional verbs where, unlike the situation with a perception verb such as 'see', no distinction can be made between a veridical and a non-veridical sense of the verb. The verb 'seek', for example, is an intensional verb in that, unlike an extensional verb such as 'find', it generates a referentially opaque context. That is why the argument,

Jones seeks a unicorn; therefore, there is a unicorn

is invalid, whereas the argument,

Jones finds a unicorn; therefore there is a unicorn

is valid, even though the two otherwise appear to have the same logical form.

The difference between these two arguments can be explained in terms of Montague's first intensional logic by paraphrasing 'seeks' as 'tries to find', so that 'Jones seeks a unicorn' is analysed as 'Jones tries to find a unicorn', which, because of the infinitive phrase 'to find a unicorn', has a different logical form from 'Jones finds a unicorn'. Thus, whereas 'Jones finds a unicorn' is analysed as ' [Unicorn(*x*) & Finds (Jones,*x*)]', which does imply the existence of a unicorn, 'Jones tries to find a unicorn' is analysed as 'Tries (Jones, [*y* (Unicorn*(x)* & Finds*(y,x)*)])', which does not imply the existence of a unicorn but rather only relates Jones to the property (intension) of *being a y such that y finds a unicorn* as a property that Jones tries to, but need not really, have. Even though the above two arguments (about Jones finding a unicorn and Jones seeking a unicorn) appear to have the same logical form (in which case they would both be valid or both invalid), they are viewed on this analysis, where 'seeks' is paraphrased as 'tries to find', as really having different logical forms. In particular, whereas the second argument has the valid form,

[Unicorn*(x)* & Finds(Jones, *x*)];
therefore, Unicorn*(x)*,

the first is assumed to have the different form,

Tries(Jones, [*y* (Unicorn*(x)* & Finds*(y, x)*)]);
therefore, Unicorn*(x)*,

which is easily seen to be invalid.

The difficulty here is that although the above logical analysis explains the difference between 'Jones finds a unicorn' and 'Jones tries to find a unicorn', it still leaves unexplained the use of paraphrase in the analysis of 'Jones seeks a unicorn'. In English this sentence clearly has the same grammatical form as 'Jones finds a unicorn', and it seems reasonable to maintain that they have the same logical form as well—which leaves us with the original problem of explaining why what then appears to be the same argument form is valid with 'finds' but invalid with 'seeks'.

It was for this reason that Montague came to replace his first intensional logic, which, as indicated, corresponds to a Russellian view of higher-order logic in which the sense-denotation, or intension-extension, distinction is not fundamental, by his second intensional logic, which corresponds to a Fregean perspective in which that distinction is fundamental. Indeed, what Montague did was add an intension-forming operator '^' and an extension-forming operator '' to (Alonzo Church's formulation of) the simple theory of types (using Church's -operator), so that if is a meaningful (well-formed) expression of the new intensional logic, then both '^ ' and ' ' are also meaningful and stand for the intension (or sense) of and the extension (or denotation) of , respectively. Relative to this framework, Montague proposed that the direct object-expression (such as the quantifier phrase 'a unicorn') of any transitive verb (such as 'find' and 'seek') should be interpreted as standing not for what that expression would otherwise stand for in its occurrence as the grammatical subject of a sentence, but for the intension (or sense) of that expression instead. In the case of a quantifier phrase such as 'a unicorn', such an intension was represented by '^[*F* (Unicorn*(x)* & *F(x)*)]', which stands for the sense of *being a property that a unicorn has,* so that both 'Jones finds a unicorn' and 'Jones seeks a unicorn' are similarly analysed (ultimately) as 'Find(Jones, ^[*F* (Unicorn*(x)* & *F(x)*)])' and 'Seek(Jones, ^[*F* (Unicorn*(x)* & *F(x)*])', which means that they have essentially the same logical form after all.

All transitive verbs, on this analysis, generate an intensional or referentially opaque context when they are applied to a direct-object expression, which means that 'find' is no different from 'seek' in this regard. Where they differ is not in their logical form, but in what additional conditions apply to those verbs as meaning postulates—such as, for example, a meaning postulate that allows the intensional context generated by 'find' to be transformed into an extensional context. (An intensional expression can be transformed into an extensional expression by applying the extension-operator; and, therefore, an intensional expression of the form ^ can be transformed into ^ , which reduces simply to .) Thus, the reason why the existence of a unicorn follows from the truth of the one sentence but not from the truth of the other does not depend upon a difference in their logical form, but rather because whereas the one verb, 'find', is subject to a meaning postulate that allows for this inference, the other verb, 'seek', does not also have such a meaning postulate associated with it. (A related but different analysis in terms of active and de-activated referential concepts — where all referential concepts, including those based upon proper as well as common names, are represented by quantifier phrases—is given in Cocchiarella [2.17]. On this analysis, a de-activated referential expression, such as 'a unicorn' in both 'Jones finds a unicorn' and 'Jones seeks a unicorn', is represented by a nominalized predicate expression of the form '[*F* (Unicorn*(x)* & *F(x)*]'. Unlike Montague's analysis, however, this analysis does not depend upon the intension- and extension-operators, but only on a conceptualist view of the difference in a type-free, second-order logic with nominalized predicates as abstract singular terms between the concepts that predicates stand for in their role as predicates and the intensional objects that their nominalizations denote as abstract singular terms.)

UNIVERSAL MONTAGUE GRAMMAR

In addition to the development of an intensional logic as a new theoretical framework for philosophy, Montague also constructed a framework within set theory that he called *universal grammar* (where 'universal' was taken only in the sense of utmost generality). Such a universal grammar was designed to contain a universal syntax and a universal semantics that could be applied to natural languages as well as to formal, artificial languages. The syntax and semantics of a natural language (or at least of a significant fragment thereof), according to Montague, could be given a description (within his universal grammar) that was no less mathematically precise than could be given for the artificial languages of mathematical logicians, so that (contrary to the claims of ordinary language philosophers) natural languages were no different in this regard from formal languages.

Montague's set-theoretic description of a language L(natural or otherwise) amounts to representing L by a system (L, R), where L is a syntactically disambiguated language (i.e. in effect, an artificial construct) and R is a two-place relation of syntactical analysis that relates expressions of L with expressions of L. (R will in general be a one-many relation because it will relate a syntactically ambiguous expression of L with several different disambiguated expressions of L as alternative analyses of that expression.) The disambiguated (artificial) language L consists in part of a free algebra (generated by a set of basic phrases), a set of structural operations on strings of expressions of L, a set of syntactical rules (specifying the type of expression that results when a structural operation is applied to a string of expressions of certain given types), and a specification of the syntactic categories of L, including in particular the category of the declarative sentences of L. The family of phrases of the different syntactic categories of L can then be defined inductively in terms of the basic phrases of L, and the closure conditions determined by the syntactical rules and structural operations of L (cf. Montague [2.29], chapter 7). By way of example, Montague specifies a set of syntactic categories, structural operations and syntactic rules for a fragment of English and shows how the various phrases of that fragment can be precisely characterized in terms of certain basic phrases of those categories. He also shows how his second intensional logic can be similarly specified in strictly formal terms.

Whereas the basic aim in syntax is to characterize the various syntactical categories of expressions of a language, including in particular the category of declarative sentences, the basic aim of semantics, according to Montague, is to characterize the notion of a true declarative sentence (under an interpretation) of that language and then, in terms of that notion, the relation of logical consequence between the declarative sentences of the language. By way of achieving this aim, Montague constructed a model theory based upon the theory of types of his second, Fregean intensional logic and showed how all the different types of intensions (or senses), as well as all the different types of extensions, can be given set-theoretic representations in his model theory. In this way, by correlating the different syntactic categories of a given language with the logical types of his intensional logic, Montague was able to characterize the semantic categories of a language (natural or otherwise), and he was then able to define the notions of truth and logical consequence between the declarative sentences of that language in terms of the model-theoretic structures (which he calls *Fregean interpretations*) associated with those semantic categories. (A Fregean interpretation includes not only a set of possible worlds, but also moments of time and contexts of use in those worlds.)

A third component of Montague's universal grammar, in addition to universal syntax and universal semantics, is a formally specified theory of translation. The theory involves correlating the syntactic categories of two languages L and L', where $L=(L, R)$ and $L'=(L', R')$, in such a way as to generate a homomorphism (a certain type of mathematical function) from the free algebra underlying L to the free algebra underlying L'. Besides translating well-formed expressions of L into well-formed expressions of L',

such a homomorphism also induces a Fregean interpretation (i.e. a certain model-theoretic structure) for *L* in terms of a Fregean interpretation for *L*. Thus, by constructing a translation function from a (fragment of a) natural language such as English into his Fregean intensional logic, Montague is able to correlate the model-theoretic structures (Fregean interpretations) defined for the latter with model-theoretic structures for the former.

'The principal use of translations', according to Montague, 'is the semantical one of inducing interpretations' ([2.29], 232). Such an interpretation is really just a set-theoretic structure and does not provide the kind of perspicuous interpretation (by means of logical forms) that a translation into Montague's Fregean intensional logic does. Indeed, even Montague, who had at one time maintained that all philosophical analyses were to be carried out as definitional extensions of set theory (cf. [2.29], 154), did not remain satisfied with the idea of set theory as a *lingua philosophica,* and it was for that reason that he went on to construct his different intensional logics. Thus, according to Montague, 'philosophy is always capable of enlarging itself; that is, by metamathematical or model-theoretic means—means available within set theory—one can "justify" a language or theory that transcends set theory, and then proceed to transact a new branch of philosophy within the new language. It is now time to take such a step and to lay the foundations of intensional languages' (ibid., 155). In constructing and applying his Fregean intensional logic, Montague showed how—through a translation (which really amounts to a precise logical analysis) of English into an applied form of that intensional logic—a variety of constructions in English, including especially quantifier phrases and intensional verbs, can be given an intuitively satisfying and natural representation/interpretation in terms of that intensional language.

SPEECH-ACT THEORY AND THE RETURN TO PRAGMATICS

The formal approach to the philosophy of language has been criticized, we have noted, by so-called ordinary-language philosophers. This criticism has been described in terms of a conflict between a speech-act (or communication-intention) theory of meaning and the formal truth-conditional theory of meaning, such as is given in Montague grammar (cf. Strawson [2.41], chapter 9). The meaning of a sentence is not in general the same as its truth-conditions, it is maintained, even when the latter is relativized to contexts of use; for, in addition to declarative sentences there are also imperatives, optatives, interrogatives, exclamatories, etc., which may have compliance- or fulfilment- conditions instead of, or in addition to, truth-conditions. The fundamental concept in the theory of meaning, on this view, is not the concept of truth but the concept of a speaker's meaning something by an audience-directed speech act (cp. Grice [2.23], chapter 5).

In performing a speech act (in a context of use), a speaker performs a number of distinguishable acts, including in particular what is called an illocutionary act, which in the simple case can be described as an act of the form *F(P)* consisting of an *illocutionary force F* and of a prepositional content *P*. The illocutionary force of a speech act determines how it is to be taken—e.g. as a statement, a question, a promise, an apology, an order, a declaration, an offer, a refusal, each of which is a different kind of illocutionary act (cp. Searle [2.38], chapter 1). Which illocutionary act is being performed in a context of use depends upon such illocutionary force-markers as verb mood, word order, punctuation signs and intonation. English and most other natural languages also have *performative verbs,* such as 'state', 'promise' 'ask', 'order', 'apologize', 'vow', that stand for different illocutionary forces. A performative sentence is a declarative sentence in which a performative verb occurs in such a way that a literal utterance of that sentence constitutes the performance by the speaker of the illocutionary act that the performative verb stands for.

Because performative sentences are in the indicative mood, some philosophers of language have thought that a semantic analysis of illocutionary acts could be given in terms of the truth-conditional semantics (relativized to contexts of use) of the performative sentences that could be correlated with those acts, and that, therefore, the logical forms of a Fregean intensional logic such as Montague's might suffice for the representation of such acts after all. Such an approach, however, gives no account of how non-declarative sentences are used to perform illocutionary acts, and in that regard it would fail to explain the relation of illocutionary entailment between performative and non-declarative sentences (such as between 'I ask if it is raining' and 'Is it raining?'). Indeed, in general, the attempt to reduce the meaning of all the different kinds of sentences that can be used in speech acts to an analysis based upon a logic only of sense and denotation (or intension and extension), or even just to a logic of extensions (as some philosophers of language insist), has failed to explain a variety of cases of truth-conditional and illocutionary entailments between sentences, and in that regard it has also failed to provide adequate identity criteria for the different kinds of speech acts that could be performed in a given context of use.

This does not mean that we must give up the project of an ideal language by which to perspicuously represent the logical forms of the different sentences that we can utter in a context of use, i.e. an ideal language by which we can represent and explain our linguistic competence in the use and understanding of language. Rather, what needs to be done is to develop intensional logic into a framework that contains an illocutionary logic as well, such as can be obtained by extending Montague's Fregean logic of sense and denotation by adding to it both new syncategorematic expressions to represent illocutionary forces and certain new values (e.g. a value of success and its failure, which can be called 'insuccess') to represent the successful performance or non-performance of speech acts in different possible contexts of use (cp. Vanderveken [2.44] and [2.45]). On this view, instead of identifying linguistic competence with the speaker's ability to understand the truth conditions of sentences, we should identify it with the speaker's ability to understand the illocutionary acts that can be performed by sentences taken literally in different contexts of use. That is, instead of representing the meaning of a sentence by a function from possible contexts of use to truth-values, the meaning is to be represented by a function from possible contexts of use to the illocutionary acts that can be performed by a literal utterance of that sentence in those contexts. Also, in addition to the syncategorematic signs for the logical constants (by which the truth-conditions of complex sentences are determined), the logical forms of the sentences in such an enlarged ideal language will now contain syncategorematic counterparts to those syntactic features of the sentences of natural language that determine which types of illocutionary acts can be performed by literal utterances of those sentences in different contexts of use.

One of the principles of such an enlarged framework is that an illocutionary act of the form *F(P),* where *F* is an illocutionary act and *P* is a prepositional content, has conditions of success as well as conditions of satisfaction. By the conditions of success of such an act is meant the conditions that must obtain in a context of use in order for the speaker to succeed in performing that act in that context, and by the conditions of satisfaction is meant the conditions that must obtain in the world of a context of use in order for that act to be satisfied in that context. This notion of satisfaction is broader than the notion of a truth condition. Thus, for example, although an assertion is satisfied if, and only if, it is *true,* an order is satisfied if, and only if, it is *obeyed;* and, similarly, a promise is satisfied if, and only if, it is *kept,* and a request is satisfied if, and only if, it is *granted*—and so on for each of the other illocutionary forces.

The conditions of success and satisfaction of an illocutionary act are determined, on this analysis, by certain components of the illocutionary force of that act—such as the *illocutionary point* of the force (which is the assertive point, the commissive point, the directive point, the declarative point or the expressive point), the *mode of achievement* (which determines how the point must be achieved), the *propositional*

content (which determines the states of affairs that must obtain or come about for an act with that force to be successful), the *preparatory and sincerity conditions* (which determine the propositions presupposed by a speaker performing an act with that force, or which express the psychological states or modes of prepositional attitudes of the speaker), and the degree of strength of the psychological states that enter into the sincerity conditions. These components of an illocutionary force are represented as parts of the logical form of that force, and the set of all possible illocutionary forces is recursively definable in terms of these components and five of the simplest types of illocutionary force that are taken as primitives of the framework (cp. Searle and Vanderveken [2.39]).

In addition to a recursive characterization of the class of illocutionary forces, the new expanded framework, which some call *general semantics,* allows for a variety of new semantic notions not realizable in intensional logic alone. In addition to *truth-conditional consistency,* for example, there is also the notion of a sentence being *illocutionarily consistent,* and, in addition to a sentence being *analytically satisfied* or *analytically unsatisfied* (such as 'I exist' and 'I do not exist', respectively), there is the notion of a sentence being *analytically successful* or *analytically unsuccessful* (such as 'I am speaking now' and 'I am not speaking now'). Also, at least eight different logical types of entailment between sentences can be characterized in the enlarged framework, such as truth-conditional and illocutionary entailments, truth-conditional entailments of success and satisfaction (cp. Vanderveken [2.45]). This enlarged framework is not at odds with Montague's intensional logic, it should be emphasized, but is really a conservative extension of the latter that simply adds a recursive theory of success and satisfaction to Montague's theory of truth. Of course, one important consequence of such an addition is that the primary units of meaning and communication are not isolated propositions but illocutionary acts of the form *F(P),* which means that many illocutionary acts with strictly equivalent prepositional contents have different conditions of success and therefore are not identical.

General semantics, on this interpretation, deals with the logical structure of all possible sentence and utterance meanings of all possible natural and scientific languages. The ideal language constructed in such a framework is intended to represent the *universals of language use,* i.e. both the formal and material universal features of both natural and scientific language. As governing the success conditions for the performance of illocutionary acts, the universal laws of this ideal language are viewed as reflecting *a priori* laws of thought, and as governing the satisfaction conditions of those acts, these same laws are viewed as reflecting *a priori* laws regarding the logical structure of the world (Vanderveken [2.44], 58ff.). Clearly, such a view brings us back to something like the *characteristica universalis* originally envisaged by Leibniz.

General semantics includes pragmatics in that it contains the notion of a possible context of use of language as an essential part. But general semantics deals with speech acts taken only literally. That is, general semantics reduces speaker meaning to sentence meaning by assuming that a speaker who utters a sentence in a context of use means to perform the illocutionary act literally expressed by that sentence in that context—when that illocutionary act, taken literally, can be performed. A speaker may intend his speech act not to be taken literally, however, as in the case of metaphor, irony and certain indirect speech acts. Also, given a conversational background, a speaker may mean to perform a secondary non-literal illocutionary act in addition to his primary illocutionary act taken literally, but one that is not in fact entailed by the primary illocutionary act in any of the senses of entailment of general semantics. These kinds of secondary illocutionary acts are called *conversational implicatures* (cp. Grice [2.23], Part I). A professor, for example, in a context in which he is asked by a student what he thinks of the latter's outline for a proposed research project, does not literally imply his disapproval when he answers 'It is typed very nicely'—but such disapproval may be conversationally implied in the context in question. The analysis and interpretation of these kinds of 'implicatures', and the development of a general theory of speaker meaning capable of

interpreting non-literal utterances, remains today a proper part of the task of pragmatics (cp. Vanderveken [2.44], 71).

Pragmatics, as the study of non-literal speaker meaning, remains then an essential part of semiotics, because 'the competence speakers have to perform and to understand non-literal illocutionary acts and conversational implicatures is part of their competence to use language and communicate' (ibid.). In this regard, pragmatics imposes an additional condition on the adequacy of a framework such as general semantics and requires a development of its own in terms, for example, of the notions of what Grice calls *conversational maxims* (or directives) and *conversational background*. Whether—and, if so, to what extent — pragmatics in the sense of the rules of conversation can be given a formal analysis and incorporated into an ideal language remains yet to be determined. In any case, the notion of a *lingua philosophica* as an ideal language containing both an intensional and illocutionary logic is no longer merely a programme but has already in many respects been realized.

CHAPTER 3
Metaphysics I (1900–45)

William James DeAngelis

INTRODUCTORY REMARKS

The first half of the twentieth century marks a change in philosophical attitudes towards metaphysics which is as sharp and dramatic as any in the history of philosophy in the English-speaking world. For the preceding three centuries, metaphysics had been a central concern of European philosophers. The central assumption of these metaphysical philosophers—that the human intellect is capable of uncovering important aspects of the nature of reality which the sciences and common sense cannot—was widespread from the time of Descartes until the present century. The bolder metaphysical systems associated with continental rationalism held that many of the most important truths about reality are of this type. Further, it cannot be denied that the work of their leading British counterparts—even those associated with the more cautious empiricist tradition—included striking metaphysical claims and rested upon deep metaphysical assumptions.

To be sure, Hume and Kant, the acknowledged philosophical giants of the late eighteenth century, offered explicit warnings about the central assumptions and the doctrines of these metaphysical philosophers. These, however, were neither heeded nor, it seems, well understood by philosophers of their own or closely subsequent generations. Later, in the nineteenth century, currents of principled anti-metaphysical thought became more common and influential in Europe and the United States. Even so, metaphysical philosophy continued to flourish on the European continent, and, in Britain and the United States, it is fair to say that it flourished as never before. As the twentieth century neared, traditional metaphysics, in its most ambitious and systematic form, was alive and well in the English-speaking world.

All this was about to change dramatically and, it would certainly now appear, irrevocably. To be sure, many prominent English-speaking philosophers of the early twentieth century and even beyond continued to engage in philosophical activities that were more or less continuous with traditional metaphysics. Nonetheless, far more powerful philosophical movements developed during this period which were destined both to threaten the very existence of metaphysics and to change its nature profoundly. These dominant tendencies of thought, when not avowedly anti-metaphysical, sought—at the very least—to place strict limitations upon both the methods and the domain of metaphysics. This essay concerns itself with these philosophical movements, their principled opposition to traditional metaphysics, and their dramatic effects on the conception, the scope, and the practice of metaphysics in Britain and the United States during this century. As such, it reflects its author's conviction that these movements are of such surpassing importance, that they alone constitute the proper focus of this effort.

ABSOLUTE IDEALISM: NEO-HEGELIANISM IN BRITAIN AND THE UNITED STATES

At the beginning of the twentieth century, neo-Hegelian philosophy was well represented by important philosophical figures in England and the United States. Doctrines inspired by Hegel were a major, if not *the* major, focus of philosophical interest and discussion. This was especially true in metaphysics. In the late nineteenth century and in the early years of the twentieth, F.H.Bradley (1846–1924) and Bernard Bosanquet (1848–1923) of Oxford, J.E.McTaggart (1866–1925) of Cambridge, and Josiah Royce (1855–1916) at Harvard were among the most prominent English-speaking philosophers. All of them held Hegelian metaphysical views. While their philosophical motives and styles varied, and they certainly differed on matters of substance, their most basic metaphysical beliefs were remarkably similar. Speaking generally it can be said that each represented, in his own way, a school of thought which was still in its ascendancy at this time and shortly thereafter. This ambitiously metaphysical school of thought came to be known as absolute idealism.

The views of this school were remarkable in many respects. For one thing they included metaphysical doctrines that were strikingly at odds with fundamental beliefs of common sense and—perhaps historically and culturally even more significant—with those of modern science. Its methods and conclusions were dramatically contrary to the traditional—and more cautious—empiricist tradition in British philosophy. This latter feature was one which its British advocates saw in a most positive light as a long overdue development. It was felt that Bradley, who was regarded as the leading figure of this movement, had brought British philosophy at last into the mainstream of European thought. For a decade or two, it even seemed that this development would prove to be permanent.

It was true enough that absolute idealism had almost nothing in common with the empirical doctrines and methods of Locke, Berkeley, Hume and Mill—arguably the most influential British philosophers of the preceding centuries. Its influence, however, was not to prove permanent in the English-speaking world. As we shall see, its prominence constituted only a brief break with long-standing traditions in British philosophy. Indeed, the most noteworthy early twentieth-century metaphysical thought in Britain can be seen to have been, in both its motives and content, a self-conscious and energetic reaction against absolute idealism, its doctrines, methods and spirit. This is most notably true of the early work of G.E.Moore and Bertrand Russell, who would prove to play a major role in discrediting the movement. Once they had rejected neo-Hegelian metaphysics, neither of the two ever wavered in his fierce opposition to it. Indeed each spent a good part of his philosophical career, in effect, constructing what he hoped would be a successful alternative. Significantly, these alternatives fell very clearly within the longer-standing traditions of British philosophy with which Bradley and the others had broken. It has been observed that Hume and Berkeley would have been sadly puzzled by the pages of Bradley or Hegel, but that either might have conversed quite naturally with Moore, and even with Russell in his less technical moments.

The work of Ludwig Wittgenstein, who, as a young philosopher, was himself influenced by Russell and, to a lesser degree, by Moore, deserves mention in this context too. While Wittgenstein never concerned himself specifically with Hegel, Bradley or their followers, his philosophical work consistently emphasized that writings like theirs amounted quite literally to *nonsense*. His remarkable statement of this view in *Tractatus Logico-Philosophicus* indeed helped inspire a prominent school of philosophy, logical positivism, which sought, as we shall see, to undermine *all* metaphysics.

The influence of Moore, Russell, Wittgenstein and the logical positivists was scarcely less dramatic in the United States than in Britain. In addition, the powerfully influential American pragmatists, notably C.S.Peirce, William James and John Dewey, were also dissatisfied with neo-Hegelian thought and sought to construct a philosophy which went right where they believed it had gone wrong. More generally, the

philosophical perspective of these influential pragmatists was openly hostile to metaphysics in its traditional forms. While Peirce and James, like Russell, held some hope that metaphysics, through great effort and radical change, could be reformed, the notion that metaphysics was a species of nonsense came to have as much currency in the United States as it did in Britain, with similar long-term results.

Certainly, absolute idealism has ceased to be taken seriously in Britain and the United States. The school, so influential at the turn of the century, when it was defended by philosophers who were highly regarded and —in some cases—very much in their prime, is barely mentioned less than one century later. Still, it is important to get some sense of what Bradley and the others believed in order to understand the vehement reaction against it which galvanized much early twentieth-century thought in England and America.

For one thing, absolute idealism was an ambitiously metaphysical school of thought. It sought to establish unassailable truths about the universe taken as a whole. This metaphysical concern with the *whole* of reality was especially insisted upon. It was contrasted with the approaches of non-philosophical disciplines which, it was believed, were necessarily partial and fragmentary. The absolute idealists insisted too, that the truths that they had uncovered were of a different sort from those established in other disciplines: they were presumed to be absolutely necessary, ultimate and essential to the very nature of reality.

Perhaps most important, Bradley insisted that reality constituted an *indissoluble unity*. To explain this, consider that we all believe as a natural matter of course that the universe contains a very large number and variety of objects that are often independent of one another, having various different properties and interrelations. Galaxies, stars, planets, people, rocking chairs, pumpkins and earthworms exist, have very different properties and can arrange themselves in different ways with respect to one another. Seemingly nothing could be more commonplace. Yet this is exactly what absolute idealism denied. Against this common mode of thought, it was urged that the universe was intrinsically an unsegmented and undifferentiable whole. The sciences and common sense, which deal with this or that *object,* with this or that *portion* of reality, were thought to involve a necessary element of distortion or falsification. Reality was essentially one—any intimation that it consisted of independent parts was condemned as necessarily false.

Hegel's British disciples never merely assumed this. Bradley set the philosophical tone by arguing for this view in a remarkable book, published in 1893, called *Appearance and Reality* [3.6]. He believed that the universe, reality or, to use his own term, 'the Absolute', did not consist of parts and that any notion that it did was, in the final analysis, incoherent. His arguments for this perhaps owed more to Zeno than to Hegel. One of his most basic premises became a subject of controversy and a special target for criticism. The view, which he regarded as a necessary truth, is known as the doctrine of internal relations.

According to it, any relational fact about an object—for example, that it is below another object—is really a fact about the intrinsic nature of the object in question. In effect, Bradley refused to take relations as ultimate and unreducible: they are not real and are better thought of as intrinsic properties of objects. The unreality of relations —itself a striking view—had, for Bradley, even more remarkable consequences. He thought it follows from this principle that whenever two things are related, each can be said to 'enter into the nature of the other'. When x is below y, then being below y is part of the nature of x and being above x is part of the nature of y, so that y is part of the nature of x and x is part of the nature of y. Now since everything presumably bears some relation to everything else, it follows that everything else enters into the nature of any given thing. Using some auxiliary principles, Bradley arrived at the remarkable conclusion that there is no 'other thing' relative to any given thing—and this, in turn, meant that the only thing that exists is one all-consuming entity. This line of thought was characteristic of Bradley who often directed *reductio ad absurdum* arguments against common modes of thought that divide reality into independent objects with relations. His intent was to show that this mode collapses, and leaves his own metaphysical view of reality as the only viable alternative. The doctrine of internal relations, which holds that relations

between presumably different objects are unreal and reduced to intrinsic properties, is a crucial step in his central argument.

It is helpful to draw some of the further consequences of this striking metaphysical claim. Since Bradley believed that reality does not consist of parts and is not (to use his own phrase of contempt) 'a bare conjunction' of objects, he boldly drew the conclusion that it was not physical. If reality were physical, then it would be segmentable and this is just what he insisted was not the case. So reality was claimed to be spiritual. Bradley was an idealist and, so, a monist too. Unlike Berkeley—British philosophy's other great idealist—who embraced idealism in part because he believed it was the only metaphysical view compatible with common sense, Bradley endorsed it for very different reasons. He saw in it the *benefit* of being antithetical to common sense, which he completely rejected.

Bradley's rejection of any segmentation in reality is connected to his remarkable conclusion that space and time—conceptually segmentable themselves—are also unreal. McTaggart attempted to supplement Bradley's case with ingenious *reductio ad absurdum* arguments designed to show that the concepts of space and time are incoherent. Far from soft-pedalling these nearly incredible claims, Bradley and McTaggart insisted on them explicitly. Far from being vexed by *any* of his surprising conclusions, Bradley and virtually all his followers were very much *attracted* to them. Their striking rejection of common sense and their recognition of only a unitary spiritual reality, jibed well with their shared sense—one that could fairly be characterized as religious or mystical—that the apparent defects of the world are somehow unreal and that, in some ultimate sense, everything is all right.

All this invites a number of very basic questions. How could the beliefs of science and common life which are so basic and which, after all, seem to serve us all pretty well, be false? Bradley acknowledged this question and insisted that such beliefs concern only *appearances,* whereas his metaphysical concept of the absolute was the only correct accounting of the reality which contrasts with those appearances. Bradley's metaphysics of the absolute was, he believed, the real truth about reality—a truth the magnitude of which only philosophy could establish.

C.S.PEIRCE: EARLY ANTI-METAPHYSICAL STIRRINGS

Charles Sanders Peirce (1839–1914) is now acknowledged as the originator of the pragmatic school of philosophy in the United States and often as its most profound practitioner. His work and thought—some of which was published as early as the 1870s—was largely unnoticed during his lifetime. While he inspired and greatly influenced the early leaders of the pragmatist school in personal discussions, his own writings remained almost entirely unpublished and did not themselves have much influence until they were compiled and published posthumously, beginning in 1931, as *The Collected Writings of Charles Sanders Peirce* [3.18]. The son of a Harvard University mathematician, he was given a rigorous home education. He had a great talent for logic, mathematics and the sciences, and he took an undergraduate degree in chemistry. Eventually he turned to philosophy. He lectured on philosophy briefly at Harvard, and then again at Johns Hopkins; he was not, however, well suited to the life of a university professor. He was a frighteningly perceptive intellectual critic who did not spare his own thoughts. He was rarely, if ever, satisfied with his own written work. His only long-term professional position was as a surveyor for the US Coast and Geodetic Service.

Peirce, like many other twentieth-century philosophers with mathematical and scientific training, was convinced that the state of philosophy could only be improved by instilling in philosophers the discipline and rigour characteristic of those enterprises. He believed that much of philosophy-as-practised failed to meet such standards. Quite early in his intellectual development, he came to the conclusion that

metaphysical thought was especially lacking in this respect; so much so, he characterized the arguments of metaphysicians as 'moon-shine'—American slang for illegally home-distilled whisky. Less colourfully, he used the term 'nonsense' to characterize metaphysical doctrines. While he did not use the latter term in nearly so technical a manner as Wittgenstein and the logical positivists would decades later, there is no doubt that there are important connections between Peirce's early view of metaphysics and their far more formally developed views. In addition, it should be noted that Peirce explicitly credited his reading of Kant's *Critique of Pure Reason* not only as an early source of his dissatisfaction with traditional metaphysics, but as an inspiration for some of his own thoughts on the subject. It is to these ideas that we now turn.

Two of Peirce's earliest writings are, 'The Fixation of Belief' and 'How to Make Our Ideas Clear', which appeared in *Popular Science Monthly* in 1877 and 1878 respectively. Although he continued for decades to develop the ideas expressed in them, they have come to stand as classic statements of his views. In them, he spelled out, albeit informally, ideas which anticipated some of the important pragmatic and positivist criticisms of metaphysical thought. His main concern was to offer a full-blown theory of inquiry. While he took an anthropological interest in actual modes of human inquiry, he was far more concerned to develop *normative* or *prescriptive* canons of inquiry. Towards this end, one of his chief concerns was the 'clarification' of theoretical terms. His main contention on this subject was elegant in its simplicity: we cannot be clear about the meaning of a theoretical term unless we are clear in advance on the practical *consequences* that are to be encountered under specifiable circumstances in virtue of which the term can be said to apply. In effect, Peirce was insisting on *practical criteria* for the application of a theoretical term. To take his own example; for the term 'hard' to have a clear meaning, we should be able to say with clarity just what we should expect—in practical terms —under specifiable conditions from an object to which the term applies. His actual suggestion, in this case, is that a hard object should scratch most other objects and should not be scratched by many other objects. His implicit claim is that a term for which there are no such practical, condition-related consequences connected to its proper application, would be a term with no meaning at all.

By extension, Peirce came to similar conclusions about propositions. He insisted that we cannot be clear about the meaning of a proposition unless we can be clear in advance about what practical consequences are, in given situations, to count in favour of its truth; if there is no clear accounting of such consequences, the proposition in question is so unclear as to have no meaning at all. It is extremely important to notice that Peirce's insistence on *practical* consequences in these contexts virtually rules out the sorts of claims made by traditional metaphysicians. Indeed, from the point of view of a metaphysician like Bradley, Peirce's practicality requirement might seem question-begging, since it insists that the meaning of every metaphysical term be linked to what Bradley believed to be mere appearances. Peirce's rejoinder, in effect, was that what Bradley called 'appearances' are better thought of as 'reality'; that if there are to be *any* criteria for the use of theoretical terms, or the truth of theoretical propositions, they can only reside within the realm of the practical. Pure metaphysics is so far removed from practical human life as to be meaningless. He stated explicitly that the propositions of ontological metaphysics, reaching no practical terminus, were 'theoretically meaningless'—amounting to nothing more than 'gibberish' (which is presumably no better than 'moonshine').

Interestingly, Peirce did believe that something deserving the name 'metaphysics' might be fruitfully pursued. Indeed, Peirce thought that some form of metaphysics might be practically testable and, at least to that extent, continuous with the sciences. It was never exactly clear what he had in mind. Although he made some modest attempts at proper metaphysical research, none of these have received much attention and they appear to be tangents to his major line of philosophical inquiry. While it is clear that he thought that

metaphysics must be testable and confirmable, he noted too that its confirming experiences would involve the most common, pervasive facts of experience rather than the specialized sorts of observations that are characteristic of the exact sciences. It is also significant that Peirce insisted that legitimate metaphysics must, by its nature, be a co-operative or social inquiry made by many investigators.

What is most important here, however, is what Peirce *rejects* and why. There are powerful principles at work: science is the paradigm for intellectual inquiry; theoretical concepts have meaning only when there are practical tests for their proper application; theoretical propositions have meaning only when there are practical tests for their truth or falsity; purported concepts and propositions for which no such practical tests exist are meaningless; finally, philosophical researches must somehow meet standards of practical testability to be legitimate. These are ideas which the American pragmatic philosophers took seriously and developed in characteristic ways throughout the twentieth century. There is much in Peirce, as we shall see, that anticipates the doctrines of the logical positivists as well. Finally, his sense that traditional metaphysics had gone wrong by completely isolating itself from practical life, while deriving from elements in Kant's thought, resonates interestingly with the philosophical perspective of G.E. Moore—to whom we now turn.

G.E.MOORE: AN APOSTLE OF COMMON SENSE

Against the philosophical background of absolute idealism, G.E.Moore (1873–1958) came to Cambridge University to study classics. As a matter of course he read philosophy and, after very briefly acquiescing to the doctrines of absolute idealism (to some degree, as expounded in his discussions with McTaggart), he rebelled against them. In so doing, he became increasingly absorbed in philosophy. He excelled in philosophical discussion and made a great impression at Cambridge. Gradually his initial intention to become a classicist weakened. By degrees, and somewhat to his surprise, he became a philosopher. It was not long before he dedicated himself almost completely to combating the influence of absolute idealism. Years later he doubted whether the world or the sciences would ever have suggested to him any philosophical problems. Rather, he believed, philosophical problems had engaged him only as a result of his hearing and reading the strange things that other philosophers espoused. Moore's early philosophical motives were so tied up with undermining the strange metaphysical claims of absolute idealism, he would probably never have become a philosopher had he not encountered them.

Moore was a unique thinker. He had a vivid and forceful personality which his philosophical peers could not help but take seriously. There was nothing flamboyant about Moore. To the contrary, his strength lay in his directness, his uncompromising honesty, and his firm independence of mind. Moore was neither quick-witted, nor particularly imaginative, but his clarity of thought and relentless commitment to truth were truly remarkable. He was never a systematic philosopher, but his approach to philosophy was fresh and original. He displayed both a strong determination and a rare ability to achieve *clarity* on philosophical problems. For him, this meant posing them, as well as expressing his views on them, with exact precision, making all necessary distinctions, leaving nothing out and leaving nothing obscure or vague. In this, he succeeded, perhaps better than anyone of his time.

Moore's most influential work pertaining to metaphysics can be divided into two categories. First, he wrote some early essays critical of the claims of, and arguments for, idealism. This work was influential and demonstrates both Moore's characteristic insistence upon clarity and his talent for making fine distinctions. Moore's early essay, 'The Refutation of Idealism' (1903), is concerned chiefly to undermine the arguments that idealist philosophers have offered in support of their position [in 3.14]. Moore tried to show that idealist thought is a web of confusions, incomplete thoughts and unjustified claims. Acknowledging that idealism (which he first, quite characteristically, took great pains to clarify with sufficient precision) might

be true, he concludes that there is no good reason to believe that it is. He takes special pains to refute Berkeley's *esse es percipi* principle. In 'External and Internal Relations', an earlier, less influential piece, he criticizes Bradley's principle of internal relations, attempting to show that the doctrine involves a major confusion [in 3.14]. These essays are essentially critical.

It was, however, much later work of Moore in which he boldly defended what he called 'the Common Sense View of the World' and rejected any metaphysical view incompatible with it, for which he is justifiably best known. That work represents thoughts that are dramatically characteristic of its author. The 'Defence of Common Sense' (1925), perhaps Moore's best-known essay, is a remarkable work which employs a strategy that is both elegant and deceptively simple [3.16]. He begins by offering a list of propositions which he calls 'truisms'. He divides these into three categories. First he asserts some commonplace propositions such as that he has a body, that he was born a number of years ago, that he has lived his whole life on or near the surface of the earth, which itself has existed for many years prior to his birth, and upon which many other human beings have lived and do live. A second category of propositions concerns experiences. Moore states that he has often perceived his own body and other things in its environment including other human bodies, and that he has often observed facts about these things. He gives some examples of these facts. They include quite particular and familiar observations about his immediate environment, recollections about the past, and facts about his own present and past beliefs, feelings and expectations. The third and final category consists of a single proposition which states that with regard to many other human beings who resemble Moore, that each of them frequently knows propositions which correspond to those Moore listed for himself in the first two categories. He insists that all of these propositions are wholly true and that he knows with certainty that each is true. He goes on to say that the meaning of each proposition is clear. Moore refers to the propositions he enumerates collectively as 'the Common Sense View of the World'.

One might wonder why Moore bothered to state all this—much less strive to state it with his characteristic clarity, completeness and care. The answer, as he insists in the article, is that many philosophers have asserted things that conflict with these very basic truths of common sense. He thought it immensely important to point out this idiosyncratic feature of such assertions. Bradley and McTaggart, for example, actually held that material objects are unreal, and that space and time are unreal. But, of course, if they really knew that they had bodies, that their bodies were near the Earth, and that their bodies had existed for many years, then that would mean that they knew things incompatible with their philosophical pronouncements. In effect, Moore was responding to such philosophers in this work as he had so many times in discussion. To the claim that time is unreal, Moore might say, 'You mean I ought not believe that I had my breakfast today *before* I had my lunch? But I know with certainty that I did!' The power of Moore's article (and of such a direct argumentative ploy) is that it places extremely plausible constraints upon metaphysical claims. It urges that everyone, including philosophers, forbear from saying things that are clearly in conflict with what he or she knows with certainty to be true. Moore thought it important to note just how far afield many metaphysical philosophers had strayed.

This strategy was bold in its conception. Whereas Moore's earlier work sought to show mistakes in the reasonings of idealist metaphysicians, the 'Defence of Common Sense' by-passed such efforts. His stance had changed dramatically, implying, as it did, that no satisfactory argument could possibly establish conclusions contrary to what each of us knows with certainty to be true. In effect, Moore was saying, 'I don't care what your argument is, if your conclusion is inconsistent with common sense, then your argument is certainly faulty because its conclusion is certainly false!'

Moore's 'Proof of an External World' is similarly bold. First given as a lecture to the British Academy in 1939 and later published posthumously in his *Philosophical Papers* [3.16], it begins with a detailing of

some of Kant's thoughts about scepticism with respect to 'things outside us'. There is a characteristically detailed discussion of the latter expression, and a detailing of what sorts of things it might refer to. He suggests dogs, planets, stars, shadows and hands as clear exemplars. The climax of Moore's presentation came when he, gesturing appropriately with his right hand, said, 'Here is one hand', and then, gesturing with his left, 'Here is another.' Thus, he concluded that there certainly *are* things outside us, adding that his premises are certainly true and that his conclusion certainly follows from those premises. So, once again, Moore rejected any notion which runs counter to what is straightforwardly and non-problematically known to all of us.

It is worth noting here that Moore never used a derisive or disrespectful tone in any of these works. He never suggested that any of the philosophers he criticized for holding views incompatible with common sense were stupid or ridiculous for doing so, although he certainly thought they were wrong. His feeling, rather, was that they had lost their way—that they had somehow lost sight of the simple but elusive fact that philosophical work has *a standing in real life* and that when its content conflicts with the most evident features of real life, then it has gone wrong.

This leaves open an important question. If Moore is correct that the beliefs of common sense are unassailable and that no philosophical views that conflict with them are acceptable, what, if anything, is left for metaphysical philosophers to do? Moore's absolute refusal to contradict the common sense view of the world, or to accept the views of other philosophers which do, might seem like a final resting place. Remembering especially that Moore's initial motive for philosophizing was to combat the strange metaphysical views of the absolute idealists, it might seem as if he had at last found a response to such views that he could accept as definitive, enduring and final. In fact, he pretty much had. Nonetheless, he did not think that his defence of common sense was the end of all such matters.

Drawing the interesting and proper distinction between understanding the meaning of a proposition and explicating or analysing that meaning, Moore insisted that it is a legitimate, even necessary, philosophical function to analyse some of his common sense propositions. As this programme developed, Moore became convinced that there was much philosophical work still to do in this area. All this work, he thought, fell under the category of analysing propositions which are known with certainty to be wholly true. Thus philosophical analysis, so conceived, would offer no major surprises and could only elaborate upon—never undermine—common sense.

What exactly did Moore mean by 'analysis'? For one thing, he recognized that it was perfectly possible to understand the meaning of a proposition without being able to state or explain its meaning. This latter endeavour required analysis. Beyond this, it is fair to say that he never developed a satisfactory general account of what an analysis of a proposition is. He admitted as much, and this may well have been his greatest philosophical frustration. One may gain some understanding of what he intended by taking a concrete example. As mentioned, Moore argued for the existence of things outside us in part by holding up a hand and saying, 'This is a hand'—a proposition he considered to be wholly true, in no way doubtful, and perfectly clear. He believed however that the proposition could be analysed, and he undertook to do so. In 'A Defence of Common Sense', he stated that such a proposition, upon analysis, is ultimately about some *sense datum*—some object of immediate awareness which is the subject of the fully analysed proposition or judgement. Beyond this, he was not clear. For one thing, he did not think that the proposition, 'This is a hand', ultimately attributed to a sense datum the property of being a hand. This leaves open the question of just what else the relationship between the sense datum and the hand in question might be. While Moore thought that the proper analysis of the proposition in question would illuminate that relationship, he never felt that he had succeeded in arriving at the proper analysis. One of the most creative approaches to this problem was formulated by Bertrand Russell.

BERTRAND RUSSELL

Old metaphysics and the new logic

Russell was a very different intellectual type from Moore. He was an accomplished mathematician who, as is well known, did much work of historical importance in logic and in the foundations of mathematics. The publication, between 1910 and 1913, of the three volumes that comprised *Principia, Mathematica*—which Russell co-authored with A.N.Whitehead—was an important event in the history of ideas. As we shall see, that work influenced his metaphysical views. Russell was an astonishingly clever man, imaginative, quick-witted and articulate. He was also a man of wide-ranging interests who was intellectually ambitious. No doubt greatly emboldened by his successes in logic, he was, for quite some time, optimistic about the prospects for employing some of the strategies which served him so well there with similar success in other areas of philosophy.

Russell always had a philosophical temperament. A contemporary of Moore at Cambridge, he too was first intrigued with, and later rebelled against, the neo-Hegelian metaphysics of the absolute idealists. His assessment of, and opposition to, absolute idealism was dispositionally different from Moore's. For one thing, Russell thought in more sweeping and systematic terms than Moore; for another, he was far less shy about impugning what he took to be the motives of the neo-Hegelians.

Some of Russell's initial opposition to absolute idealism stemmed from the suspicions he held regarding the philosophical motives of its proponents. At times he felt that their motives were not entirely rational, and, perhaps, even dishonest. This should not be under-estimated. The proponents of absolute idealism were the objects of some of his most scornful criticism. He came to regard Hegel, Bradley and many of their followers as 'paradox peddlers' who, he believed, were less motivated to understand the world than they were to convict it of unreality in the interests of a supra-sensible absolute.

Russell made his objections of substance clear as well. Significantly, they were quite different in focus from Moore's. Whereas Moore's criticisms were quite specifically aimed at this or that proposition or argument, Russell's focus was far more systematic. More or less independently of his dislike of the metaphysical conclusions of Hegel and Bradley, he came to think (in fairness, with justification) that their thoughts about logic, which played an important role in their metaphysics, were unsophisticated and antiquated.

This came out in a number of ways. Russell, in his work in logic and the foundations of mathematics, was determined—though this was by no means his only concern—to revolutionize and systematize the discipline of logic. If his ambitions were high, so were the standards of rigour he employed. Not only did his work bring together many dramatic innovations—both his own and those of other important thinkers—into the discipline, but it also helped direct public attention to these improvements. In the end, his work played a major role in building a new consensus among philosophers and mathematicians of the twentieth century concerning logic. Needless to say, philosophers rarely achieve such successes.

When Russell first read Hegel and Bradley, his work in logic was only beginning. Yet, he detected, even then, elements in their thought which, he felt, were utterly at odds with a correct sense of what logic should be. He wrote of these misgivings, expressing in a tone of undisguised scorn, his assessment of Hegel's *Greater Logic,* as 'muddle-headed nonsense'. Later on, he gained greater clarity about these matters. In the preface to *Principia Mathematica,* written quite a few years after Russell's dramatic break with monistic, idealist metaphysics, he explains

> The logic, which I shall advocate is atomistic, as opposed to the monistic logic of the people who more or less follow Hegel. When I say that my logic is atomistic, I mean that I share the commonsense belief that there are many separate things; I do not regard the apparent multiplicity of the world as consisting merely in phases and unreal division of a single indivisible reality.
>
> [3.22, I:vii]

This almost makes it look as if Russell built his metaphysical presumptions into his logic, but the impression is misleading. As it turned out, Russell's reasons for advocating an 'atomistic' logic were, to a great extent, unrelated to his metaphysical predispositions. He, and other logicians on the cutting edge—many of whom were not at all interested in metaphysics—were mostly concerned with the development of a logic with strong deductive and expressive power. Those were the main criteria for judging success. It was by such standards, and not quirks of metaphysical temperament, that an atomistic logic developed.

How did absolute idealism conflict with what have come to be accepted as correct logical procedures in the twentieth century? It is possible to give a synoptic view of some of the connections. For one thing, Bradley's doctrine of internal relations conflicted with a very basic feature of modern logic as developed in *Principia Mathematica*. That doctrine, as we have seen, held that what we think of as relations between supposedly separate objects are actually illusory. Connected with this, it held that relational terms can be dispensed with and replaced by terms designating properties of individuals. This not only conflicted with Russell's intuitions, but he soon was able to show on logical grounds that some relational terms—most notably those associated with asymmetric properties such as 'north of', 'older than', 'higher than', and 'below'—cannot plausibly be reduced to individual predicates in this way. For these and other technical considerations, modern logic allows relational statements as basic and irreducible, and presumes that they are capable of being true. To this extent, it can be said that twentieth-century logic has repudiated, if it has not refuted, late nineteenth-century neo-Hegelian metaphysics.

Logical constructionism

Russell's own metaphysical views changed considerably during his life. After rejecting idealism, he embraced an extreme form of realism which he was soon to abandon as hopelessly confused. In *The Problems of Philosophy,* published in 1912, he embraced a version of the causal-representative theory of perception of Locke and Descartes. Shortly thereafter, Russell's metaphysical thinking changed dramatically. He conceived, employed and, for quite some time, remained committed to a genuinely innovative approach to metaphysical problems. It was connected to a strategy which he had used successfully in his work on the logical foundations of mathematics. He called it 'logical constructionism'. When employing it in the context of metaphysics he stated it in this way: 'Wherever possible, logical constructions are to be substituted for inferred entities' [3.24, 155].

What did this mean and how did this apply to metaphysics? For centuries after the time of Descartes, modern philosophers have tended to believe that physical objects are not directly perceived. The view, while no longer pervasive, persists to this day. To this is added the conviction that what we are directly aware of in perception is something accessible only to the individual perceiver which is caused by, but not identical to the object of perception. This element of direct awareness can be thought of as an inner experience which is an end point in the process of sensation and which represents the physical object being perceived. The experience of an object represents and is caused by the object; they are not the same. So, on this view it is theoretically possible to have qualitatively exactly the experiences that would normally result from perceiving, say, a pumpkin without their being caused by a pumpkin—and such things do seem to

occur in dreams and hallucinations. Even worse, if all one ever experiences directly are inner experiences or immediate sense data, then how could one ever know that these represent independent physical objects? On the view in question, there could, in principle, be no direct check of this: since experiences are all one can ultimately examine, one could never confirm whether they are caused by extra-experiential objects. In short, if such a view of perception were true, then one could not know it. The problem here is, in large measure epistemological: How could one know on the basis of inner sense data that there are physical objects? Russell took this problem seriously. His response to it was to employ logical constructionism. Its ramifications were significant for metaphysics as well as epistemology.

His strategy was to analyse troublesome entities in terms of more familiar or less troublesome ones. For example, the problem at hand is how to justify a belief in physical objects given that we are directly aware only of sense data. There seems, in the final analysis, to be no way of *inferring* the objects from the immediate sense data. Russell's innovative alternative was this: treat the physical object not as a distinct entity to be inferred from sense data, but as what he would call *a logical construction out of sense data*. What does this mean? Russell's suggestion was, in effect, to treat physical objects not as *independent of* sense data but rather as *analysable in terms of* sense data. This meant, in effect, treating physical objects as metaphysically non-basic and sense data as the more fundamental category of being.

This suggestion was to be carried out by showing that all propositions about physical objects can be, in principle, analysed in terms of propositions about sense data. If successful, this procedure would, Russell thought, solve the philosophical problem about physical objects which proceeds on the assumption that propositions about sense data and propositions about physical objects are logically independent. He explored this possibility in *Our Knowledge of the External World* which was published in 1914 [3.19]. Two papers, 'The Relations of Sense-Data to Physics' and 'The Ultimate Constituents of Matter', which were published in 1914 and 1915 respectively (and reprinted in his *Mysticism and Logic and other Essays* in 1917 [3.20]), employed the same strategy. Russell adapted the technique of logical constructionism to mental phenomena in *The Analysis of Mind,* published in 1921 [3.21]. Only in *The Analysis of Matter,* published in 1927 [3.23], did Russell begin to abandon this strategy, but, by then, it had already exerted a powerful influence upon a generation of philosophers.

Logical atomism

It is important to recognize that this creative metaphysical strategy was ultimately viewed by Russell as one feature of a larger, more ambitious and systematic philosophical programme. This was explained in 'The Philosophy of Logical Atomism', a remarkable work published in two instalments in 1918 and 1919, which established—in overall terms, if not in final detail—what was to be Russell's more global approach to metaphysics for much of the period during which he did his most respected work in the area [3.25]. His implementation of the programme led to different results at different times. He never was able to satisfy himself that he had employed it so as to achieve a final or definitive result. It seems clear, however, that during his most productive years, he did not seriously doubt the underlying assumptions of the programme itself.

Russell wanted to use the new logic to establish something enduring in philosophy. The philosophical system he envisaged was certainly metaphysical in nature. His idea proceeded from his assumption, often stated in many of his writings, that the new logic of *Principia Mathematica* represented the formal structure or syntax of a 'logically perfect language'. What it lacked, of course, was a vocabulary. Russell's metaphysical programme was, in effect, to decide upon that vocabulary which, when added to the syntax provided by the new logic, would complete the search for a logically perfect language.

Russell felt that common language tended often to confound the search for truth. For one thing, as he showed wonderfully well in his work on logic (especially in his landmark essay, 'On Denoting', 1905), the surface forms of a natural language like English often obscure the logical form of a proposition or of an argument [3.25]. One of the most striking successes of modern logic is that it provides a language carefully constructed to lay bare the logical structure of propositions and arguments. In a similar way, Russell thought, the logically perfect language he sought would not only lay bare the logical structure of its propositions, but would—when the details of its application to the world were clarified—also lay bare the logical structure of reality. Satisfied that he had gone a long way towards laying bare the *syntactics* of a logically perfect language, he proceeded to set his sights on *semantics*.

How did Russell think he could arrive at a vocabulary for such a language? Here, he made a number of assumptions he regarded as unassailable. First, he held that all the propositions in such a language would either be basic—'atomic' propositions he called them—or else analysable into basic propositions. He held that the non-basic or 'molecular' propositions would be truth-functions of the atomic propositions—that is, the truth or falsity of any molecular proposition would be a function of the truth or falsity of the atomic propositions out of which it is constructed. Second, he believed that atomic propositions served to state facts—the basic or atomic *facts* in the world. The atomic propositions of a logically perfect language were said to be *logical* atoms and the facts which they corresponded to were taken to be *metaphysical* atoms. His programme, then, amounted in large measure to arriving at a satisfactory account of what an atomic fact is and what its constituent elements are.

This issue fascinated and vexed Russell, but he was never able to resolve it. He had two powerful philosophical intuitions regarding the matter. First, he was strongly inclined to believe that atomic propositions were about *particulars* to which they referred. Atomic facts, he thought, should have particular constituents. Second, he was greatly attracted to the view that these particulars are *objects of immediate awareness*. For some time he wanted to identify the constituents of atomic facts with sense data—an assumption which perfectly jibed with his logical constructionist programme. Indeed, it constituted his purest empiricist intuition—amounting, as it did, to the opinion that all meaningful propositions ultimately refer to immediate experiences. Though he struggled to do so, Russell could never fully accommodate a fully articulated account of atomic facts with either of these two assumptions, and he found difficulties, too, with reconciling the assumptions with one another.

These difficulties notwithstanding, Russell never completely abandoned the hope that metaphysical clarity might be achieved. Ironically the metaphysical thoughts of his logical constructionist/logical atomist period were to stimulate his friend and collaborator Ludwig Wittgenstein to thoughts of his own, which would soon inspire him to write one of the most influential, vivid, and radically *anti-metaphysical* philosophical works of the twentieth century.

WILLIAM JAMES: PRAGMATISM, METAPHYSICS AND NEUTRAL MONISM

William James was the first great public exponent of pragmatism. Like so many of the figures discussed here, he was trained in science and approached philosophy with the attitude of a reformer. Specializing in medicine and psychology, he taught at the Harvard Medical School for some years before he joined its philosophy faculty. Inspired by Peirce, James sought to expand pragmatic principles and apply them to the major problems of philosophy. He was confident that pragmatism was essentially correct and destined to have a revolutionary effect upon philosophical thought. Of the philosophers treated here he was certainly the least careful about details. While his ideas were novel and sweeping in their consequences and his written expressions of them were remarkably vivid and engaging, his most powerful thoughts were

frequently not completed. Nonetheless his writings had a great influence in both the United States and Britain. There was, in James, a strongly empiricistic element of thought. Indeed, he described himself as a 'radical empiricist'. To that extent, he was a principled opponent of traditional metaphysics in general, and absolute idealism in particular. There was also, in James, a great respect for religion. He strove, in much of his work, to justify religion on pragmatic grounds, without compromising the empiricistic, pro-science, underpinnings of his thought. Whether he ultimately succeeded in this is an interesting, and very much open, question. It is, however, beyond the scope of this essay which will not address James's views on religion, but, rather, concentrate on the underpinnings of his thought.

James explicitly acknowledged a great philosophical indebtedness to Peirce. He was greatly impressed with Peirce's insistence that theoretical propositions should directly connect with practical consequences and shared Peirce's conviction that the propositions of traditional metaphysics characteristically failed to so connect. As such, James expressed a similar hostility to most metaphysics. His development of Peirce's main contentions placed special importance on the failure of metaphysical propositions to have *experiential* consequences. In his last work, the posthumously published *Some Problems of Philosophy,* he wrote:

> The pragmatic rule is that the meaning of a concept may always be found, if not in some particular which it directly designates, then in some particular difference in the course of human experience which its being true will make.
>
> ([3.9], 60)

James believed that many familiar metaphysical doctrines were not meaningful, precisely because they imply nothing relating to the course of human experience; more specifically, such views are consistent with *any experiences whatsoever*. James regarded this as a fatal defect in any purported view. A colourful writer, James often expressed the point metaphorically by writing that such metaphysical views have no 'cash value'.

Nonetheless, James, like Peirce and Russell, did not want to end metaphysics altogether; rather, he wished to make it intellectually respectable. He believed that meaningful metaphysical discourse is possible, going so far as to suggest that metaphysical philosophers occasionally make valuable suggestions —legitimate observations with genuine 'cash value'. For example, in *Pragmatism,* published in 1907, James distinguished between two forms of materialism [3.10]. The first is the traditional doctrine of material substrate which postulates unperceivable entities in which the perceivable qualities of objects inhere. This view, of course, he regarded as empty or meaningless, since it had no 'cash-value' link to any experiential consequences. Significantly, he commends Berkeley, at least, for pointing out this defect in the view, describing Berkeley's objections as 'absolutely pragmatistic'.

Against this empty version of materialism, James urged what he thought was a legitimate form. He suggested that one might deny material substrate as vehemently as Berkeley did and still be a materialist 'in the wider sense, of explaining higher phenomena by…laws of physical nature' ([3.10], 93). This meaningful version of materialism holds that the various phenomena in the world that we naturally judge to involve intelligence, purpose, consciousness or intent can all, in principle, be accounted for in terms of the laws of physical science. While not specifically advocating this view, he took it to be, at least, meaningful. His thought would seem to have been that the view does have links to possible, observable consequences: roughly, it will stand or fall according to whether or not certain kinds of explanations for certain kinds of phenomena are discovered. This is no matter of *simple* observations, but it would appear at least to meet James's rough pragmatic requirement that a conception have some implications that make a difference

relative to the course of human experience. Here, then, is meaningful metaphysics. It is testable and continuous with science.

James made a similar distinction with respect to the notion of personal identity. He regarded Descartes's analysis of the notion as pragmatically meaningless. Locke's account, on the other hand, he took seriously as a worthy contribution to philosophy. Briefly, Descartes believed that the sensations, thoughts, affections, memories, dreams and fantasies of a given individual belong to that individual in virtue of being contents or modes of the same underlying spiritual substance or soul. Descartes explicitly distinguished this spiritual substance itself from its contents, and acknowledged that it is never itself experienced; still, he urged that the unity of a person consists in the unity of this underlying mental substance. James offered a spirited pragmatic criticism of this view. This conception of mental substance, he argued, is entirely empty, since its purported existence cannot in any way register in real experience. There would be no way, in experience, to distinguish its presumed presence from its absence—and no way to detect a situation where one enduring unchanging mental substance is suddenly replaced by another. These would be, in James's parlance, 'distinctions without a difference'.

Against this, he commended Locke's quite similar criticism of spiritual substance as well as Locke's alternative analysis of personal identity which he praised for reducing this notion to its pragmatic value in terms of experience—namely, the fact that at one moment in life we remember other moments, and feel them all as parts of one and the same personal history. James never explicated Locke's view with care nor did he explain exactly why he so approved of it. He evidently thought that by citing consciousness as the locus of a person, and memory as (in some way) its principle of unity or identity, Locke had succeeded at least in reducing personal identity to the right sorts of terms—namely features of experience. A continuing person is a continuing stream of consciousness; and what unifies individual experiences into a continuing stream has to do with the possibility of certain kinds of memory interrelations among these experiences.

These remarks anticipated and, in part, influenced some of Russell's metaphysics. There is a deep suspicion of most old-style metaphysics, a hopeful sense that metaphysics can be reformed, and a strong conviction that a correct metaphysics would have to use terms and propositions whose ultimate content is experiential. Like Russell, James was an empiricist-minded metaphysical reformer. It is worth noting that his overall view of metaphysics inspired one of Russell's most radical strategies—a subject to which we now turn.

James was drawn to phenomenalism, the view—of which Russell's logical constructionism was an instance—that physical objects can somehow be identified or reduced to experiences. There was nothing terribly radical in phenomenalism *per se,* and James, characteristically, did not try to work out the details of such a view with nearly the same care as did Russell. He did conceive however, of a quite innovative extension of this view from physical objects to minds or consciousness. James first explained this conception in an essay published in 1903, 'Does Consciousness Exist?' [3.12]. Believing that physical objects can be identified as suitably interrelated sets of experiences, he further suggested—perhaps following Locke's hint—that minds or streams of consciousness could be analysed using the same general strategy. Such a view, he reasoned, was not only plausible, but involved a wonderful sort of conceptual economy: specifically, only one ultimate category of existence—namely experience—needed to be postulated. In effect, he was suggesting a new form of monism in which the ultimate 'stuff' of the universe was neither mind nor matter, but pure experience.

James very much liked an interesting consequence of this view: namely, that one and the same experience can be part of a set of experiences that constitutes a physical object *and also* part of a set of experiences that constitutes a stream of consciousness or a conscious mind. This observation was, he thought, liberating in that it undermined deep Cartesian assumptions about the radical separateness of mind and body from which

flowed seemingly endless metaphysical puzzles. This non-idealist, non-materialist form of monism became known as neutral monism.

Russell, influenced by James, embraced neutral monism for some time. His book, *The Analysis of Mind,* published in 1921, constitutes a remarkable attempt to develop a metaphysics along neutral monist lines [3.21]. As it turned out, the view was not to prove influential. In the long term, subsequent generations of philosophers were to uncover deep problems with phenomenalism, an essential component of the view. More immediately, the viability of metaphysics of any sort was about to come under the severest scrutiny.

LUDWIG WITTGENSTEIN: METAPHYSICS OVERTHROWN

It is not entirely clear whether or not Ludwig Wittgenstein (1889–1951) should be included in an essay restricted to English and American philosophers. He was born and raised in Vienna. He wrote philosophy in German, his first language. Dispositionally, he was, in many ways, Viennese. Yet, his professional career in philosophy was pursued entirely at Cambridge and he eventually became a citizen of the United Kingdom. Many of his closest friends and most of the relatively few individuals with whom he had serious philosophical discussions were British. His influence in the English-speaking world is extensive. Finally, there is a great deal of precedent for treating Wittgenstein's views in works on British philosophy.

Wittgenstein was a difficult, enigmatic individual and his writings are extremely daunting. Regarding their ultimate value, it is significant that many contemporary philosophers—including quite a few who do not share his conclusions—regard him as a philosopher of the highest historical importance. He wrote only two books for publication. One, *Tractatus Logico-Philosophicus* (1921), is said to represent 'the early Wittgenstein'; the other, *Philosophical Investigations* (1953), 'the late Wittgenstein'. It is the early work and thought of Wittgenstein and its influence that was to impact upon the first half of this century.

Wittgenstein was trained as an engineer, became interested in problems in the foundations of mathematics and went to Cambridge to study with Russell, who quickly came to regard him as a philosophical equal. Wittgenstein took a keen interest in Russell's philosophical work and, although the two never co-authored a work in philosophy, it is proper to say that they were collaborators for an extended period of time before World War I. In 'The Philosophy of Logical Atomism' Russell explicitly cites Wittgenstein's major role in shaping his ideas. Wittgenstein, in the *Tractatus,* cites Russell's ideas as an important stimulus. The two works share many central themes—but their differences are significant too.

Perhaps the most striking feature of the *Tractatus* is its explicit rejection of metaphysical philosophy. This rejection was of the most radical sort. Wittgenstein did not claim, as Moore did, that metaphysical propositions are often *false*. He did not hold, with Russell or Peirce, that metaphysical philosophy as traditionally practised was logically sloppy and needed to employ rigorous new techniques in order to become a worthy subject of study. Instead, he stressed that metaphysical philosophy by its very nature was *meaningless*. The writings of traditional metaphysicians, he insisted, fail even to present propositions that are capable of being either true or false. They quite simply fail to make sense at all.

The *Tractatus* is a difficult book. It is a very short, but extremely concentrated work. Its style is oracular. It consists of short entries that are systematically numbered. Most are terse or aphoristic. They concern language, logic, thought, the world and, most important, the interrelations among them. Its views about these subjects are strikingly original, but certainly not commonsensical. The reader is offered almost nothing in the way of guidance. Many difficult points are never clarified. Central contentions are barely supported. The author says nothing in the main text about the development and evolution of his philosophical conclusions. For decades the book was not well understood— and there is still much disagreement about many points of its interpretation.

Wittgenstein explains in a short preface that the *Tractatus* seeks to show that there is a limit upon 'what can be said'—by which he means, of course, on what can be said *meaningfully*. Employing the metaphor of a limit, he writes, 'on the other side of the limit will be simply nonsense'. In outline, at least, his overall strategy emerges fairly clearly: in showing the limits upon what can be meaningfully expressed in language, it will become clear that metaphysics (as well as ethics, aesthetics and religion) lies on 'the other side'—in the realm of 'simply nonsense'. Wittgenstein intended nothing less than to show that philosophers who tried to write metaphysical, ethical, aesthetic or religious works necessarily succeeded in producing only nonsense. In Wittgenstein's view, they quite straightforwardly had nothing to say because *there was* nothing to say. Unsurprisingly, this idea proved to be provocative in the extreme. While it inspired a prominent and vigorous school of philosophy—the logical positivism advocated by members of the Vienna Circle and their followers—it also elicited passionate criticism. Wittgenstein characteristically wanted almost nothing to do with either his self-professed followers or his critics. Believing he had definitively answered the most important questions of philosophy, he behaved with admirable consistency and gave the subject up entirely. He trained as a schoolteacher, taught in rural Austrian elementary schools, worked as a gardener, designed and built a house for his sister —but for about a decade after completing the *Tractatus,* Wittgenstein did no work in philosophy. Only when he began to doubt his Tractarian views did he return.

Wittgenstein's rejection of metaphysics in the *Tractatus* was a consequence of that work's novel view of language. Unlike Russell, who thought of a logically perfect language as an ideal alternative to ordinary language, the early Wittgenstein believed that such an ideal lay hidden beneath the surface forms of ordinary language. Indeed, he appears to have thought that something like Russell's ideal had to underlie common language in order for it to work at all. He believed that ordinary language required, and possessed, an elaborate logical understructure. That difference aside, borrowing from Russell, he believed that all meaningful propositions are truth-functions of atomic propositions. To this, he added a strikingly new idea: atomic propositions were *pictures* of atomic facts. The details of this claim are intricate and difficult, but he was explicitly clear on one consequence of it: the truth or falsity of an atomic proposition can never be established *a priori*. Each is a picture, and so, its truth or falsity is a matter of whether it correctly or incorrectly pictures the world. Ascertaining the truth or falsity of an atomic proposition requires comparing the proposition with the world. Its truth or falsity, then, is evidently an empirical matter. An atomic proposition is true if and only if the world contains the fact pictured in the proposition.

Wittgenstein believed that all propositions are either atomic or else truth-functions of atomic propositions, which he, following Russell, called 'molecular'. He took great care to explicate the notion of a *tautology*—that is, a molecular proposition which is true no matter what the truth or falsity of its components. For example, suppose *P* is an atomic proposition and consider the proposition 'Either *P* or not-*P*'. This very simple molecular proposition will be true whether its single atomic component, *P,* is true or false. It is a *logical* truth. Its truth is a matter of its logical structure and is compatible with any factual situation in the world. It is certainly true, but it is an empty or trivial truth which really gives us no direct factual information about the world. He recognized, of course, that there are logical falsehoods ('Both *P* and not-*P*' might serve as an example) which are false in virtue of their logical form alone, which—like tautologies—convey no factual content.

Wittgenstein made the powerful claim that tautologies constitute the only species of *necessary,* or *a priori* truth. All other truths depend upon the factual nature of the world. First, atomic propositions either correctly picture the world or they don't. Their truth depends upon nothing more than what the world is like. Those molecular propositions which are not tautologies (and not logical falsehoods) will turn out to be true only on *some* patterns of truth or falsity among their atomic components. So their truth or falsity will

always depend on which of their atomic components are true and which false, which, in turn, is inevitably a mere matter of fact.

In overview, Wittgenstein held that there are just two sorts of truths. Tautologies are *a priori,* necessary truths—but they are devoid of factual content. All other truths require, in effect, that the world be a certain way—which is a contingent and *a posteriori* matter. He was clear and explicit that this left no room for metaphysical truths, which purport to be both necessary and also to transcend mere facts in their significance. For him all necessary truths are empty and all truths of substance are merely factual. There can be no significant truths which go beyond empirical facts, while traditional metaphysics claimed to establish such trans-empirical truths. Wittgenstein's scheme, then, leaves no room for traditional metaphysics. It was these details of Wittgenstein's rejection of metaphysics that so appealed to the logical positivists and shaped their opposition to metaphysics.

WITTGENSTEIN AND THE LOGICAL POSITIVISTS

Shared beliefs

During the 1920s, a remarkable group of like-minded philosophers formed in the city of Vienna. The group, known as the Vienna Circle, came together under the leadership of Moritz Schlick (1882–1936). They were philosophers who were, as a group, remarkably well schooled in mathematics and the sciences as well as in philosophy. Its leading members included Otto Neurath, Freidrich Waismann, Hans Hahn, Rudolf Carnap, Gustav Bergmann, Herbert Feigl and Olga Hahn-Neurath. Karl Popper was more loosely associated with the Circle. They were to exert a profound impact on philosophical thought in this century.

As with Wittgenstein, it is not easy to decide whether to include these thinkers in an account of philosophy in Britain and America. None of them was born in either country. None was a native speaker of English. However, some of them would emigrate to English-speaking countries in the 1930s or 1940s. Carnap and Feigl were to establish themselves in the community of philosophers in the United States during their later years. Their views were as influential in the English-speaking world as anywhere. They were themselves influenced by the early work of Russell and Wittgenstein—indeed, Schlick explicitly stated that the *Tractatus* had brought modern philosophy to a 'decisive turning point'. At his urging, a number of the Circle's members engaged in a collective, systematic reading of the *Tractatus*. They admired the work, found much in it to agree with and were inspired by it. Schlick prevailed upon Wittgenstein to hold discussions with some members of the Circle when the latter returned to Vienna during the late 1920s. Later, two younger philosophers—W.V.Quine, an American, and A.J.Ayer, an Engishman—were to establish contacts with the Circle. The former became one of the most brilliant and important American philosophers of this century; the latter, the leading exponent of the Circle's views in the English-speaking world and a master of clear, lively philosophical prose. While it is not credible to think of the original formation of the Circle as an event in the history of British or American philosophy, the group as a whole certainly exerted an influence in those histories—nowhere more than with respect to metaphysics. A brief account of their overall view of the subject— especially as it relates to that of Wittgenstein—is certainly appropriate.

The members of the Vienna Circle self-consciously thought of themselves as exponents of a philosophical movement. In many respects they behaved like members of a political movement. They held congresses, published philosophical journals for the dissemination of their views and even issued a joint manifesto, 'The Scientific World-View: The Vienna Circle' (1929). For more than a decade they were a major force in European philosophy and, as mentioned, their ideas had a dramatic impact in the English-speaking world.

While they disagreed on some important points of philosophical substance, they were in remarkable agreement in their overall view of many philosophical matters. Their shared view was called 'logical positivism' or 'logical empiricism'. While their interests included the philosophy of science, the foundations of mathematics, epistemology, the philosophy of language and ethics—it was, perhaps, their view of metaphysics that inspired the most interest and controversy.

In this respect, at least, the views of the positivists were virtually identical to those expressed by Wittgenstein in the *Tractatus*. They accepted the view of Wittgenstein (indeed, Schlick appears to have arrived at much the same view independently) that all meaningful propositions are either tautologies or else factual and *a posteriori* in nature. They sympathized with Russell and Wittgenstein's notion that every meaningful factual proposition is a truth-function of basic propositions. As such, they agreed that each such factual proposition has a specific set of truth-conditions, and that the question of whether or not those conditions obtain is empirical. Although they did not accept Wittgenstein's picture theory of meaning, they took his insistence that the basic propositions of language must be compared with the world to establish their truth or falsity to be a clear signal that he had *verification by observation* in mind. Attributing even greater importance to the notion of verification by observation than Wittgenstein had, they linked it to a shared principle around which they rallied. This they called the verification principle.

The rough idea behind this principle (the members of the Circle never settled upon a *precise* definition) was this: it is a mark of a meaningful non-tautological proposition that there be, in principle, a method of verifying it empirically. Conversely, if there is, in principle, no way to verify a purported non-logical proposition, then it is not a meaningful proposition—it is what the positivists called a 'pseudo-proposition'. They believed all the supposed 'propositions' of traditional metaphysicians to be pseudo-propositions which wrongly presumed to describe a transcendent reality necessarily outside the realm of any possible observational verification. Thus, while its underpinnings were slightly different for the positivists, they shared with Wittgenstein the view that the writings of traditional metaphysicians are factually and theoretically meaningless.

Shared problems

If Wittgenstein and the positivists shared basic beliefs about language and the impossibility of metaphysics, they also came to see a number of difficulties with their view of these matters. First, there was a problem with their overall views on language and metaphysics which was both fundamental and almost embarrassingly ironic. Upon examination, it appeared that their shared view of language—which ruled out metaphysics as meaningless—had exactly the same effect when applied to itself; that is, by the tenets of their position, the position was itself meaningless! This, of course, suggested that there was something fundamentally wrong with their shared position.

The problem is perhaps easiest to explain with respect to the verification principle of the positivists. That principle, in effect, allows that, tautologies aside, only verifiable, empirical propositions can count as meaningful truths. But what of the principle itself? It certainly did not appear to be an empty tautology—indeed, the positivists trumpeted it as if it had the same sort of significance as did the law of gravity. They certainly were disinclined to view it as empty. However, the principle itself did not appear to be empirically verifiable either—after all, the positivists' acceptance of it was not the result of any scientific observations or experiments, nor did it seem that any such observations could serve to confirm it. This problem vexed some members of the Vienna Circle for some time and they were never to agree upon a resolution. Thus, the Circle—which endorsed the verification principle by consensus—not only could not agree upon a proper formulation of it, they were also at pains to show how it could be rescued from itself.

This problem was no isolated paradox. The positivists, by restricting meaningful truths to tautologies and empirical propositions, were similarly at pains to show how any of their philosophical pronouncements could count as meaningful. After all, the members of the Circle wrote books on philosophy which were certainly works neither in science nor in logic, however much they admired those disciplines. How, then, could their own words count as meaningful? Further, this seemed to lead to a dilemma: with this problem still unresolved, the positivists could not condemn metaphysics without condemning their own condemnation of it; and, if they opted to ignore this and continue writing their books, it was hard to see how they could, with consistency, condemn metaphysicians who did the same.

Similar difficulties were even more dramatically interwoven into the fabric of Wittgenstein's *Tractatus*. Its author, ever reflective, was explicitly well aware of them. Specifically, he recognized that the sentences of that book were neither tautologies nor empirical propositions and so, on Tractarian grounds, must be counted as nonsense. Far from trying to avoid this conclusion, Wittgenstein embraced it—and did so in a spirit that approached triumph. Towards the end of the *Tractatus,* Wittgenstein wrote the following:

> 6.54 My propositions serve as elucidations in the following way: anyone who understands me eventually recognizes them as nonsensical, when he has used them—as steps—to climb up beyond them. (He must, so to speak, throw away the ladder after he has climbed up it.)
>
> He must transcend these propositions, and then he will see the world aright.

Wittgenstein, then, flatly admitted that the sentences of the *Tractatus* amounted to nonsense—but, he urged, it was helpful nonsense that showed or pointed to or elucidated something important that cannot, strictly, be said. Granting this, however, it might be asked whether a metaphysician might make the same, or similar, plea on behalf of his or her own 'transcendent' views. Presumably, Wittgenstein would have resisted such a plea on behalf of metaphysics, somehow insisting on a difference between the 'elucidary' nonsense of the *Tractatus* and the misleading nonsense of metaphysics.

For Wittgenstein, there was another parodoxical aspect to his rejection of metaphysics. The *Tractatus,* for all its anti-metaphysical conviction, itself contains sentences that look for all the world to be as traditionally metaphysical as any pronouncement of, say, Plato, Leibniz or Bradley. Readers of the *Tractatus*—including most members of the Vienna Circle—did not pay much attention to the very earliest or the very latest passages of that book. This is hardly surprising. Those passages contain extremely difficult paragraphs that seem jarringly discontinuous with the rest of the book which, relatively speaking, and, at least in outline, is easier to understand. In the opening passages, for example, Wittgenstein engages the same subject that had so troubled Russell—namely the nature of atomic propositions, atomic facts, and their constituents. While Wittgenstein never gives an example of an atomic proposition and appears to have thought that they lay deeply obscured beneath the surface phenomena of language, he does offer a number of remarks on the subject. He holds that atomic propositions are concatenations of elemental names; that the propositions picture atomic facts; and that the names refer to the basic constituents of those facts which he calls 'simple objects'. These simple objects are, in the Tractarian scheme of things, nothing less than the ultimate referents of language, and so the ultimate furniture, so to speak, of the world.

His characterizations of these simples are most remarkable. He insists upon their absolute simplicity, indivisibility, indestructibility and timelessness; indeed, his words suggest entities no less remarkable and extraordinary than Platonic forms, Leibnizian monads or perhaps even Bradley's absolute. Further, while allowing that these simples are capable of relating to one another in various ways, he states that the set of possible variations—of possible facts—is fixed as a matter of *necessity,* that it is timeless and unchangeable, established, as it were, once and for all. Taking him at his word, it would appear that this

necessity is nothing less than a *metaphysical* necessity, which determines the possibilities for the world independent of language or thought. He uses the expression 'the form of the world' to elucidate this set of possible arrangements of the simples into facts—a set which, he adds, determines and fixes the set of possible propositions about the world. This would appear to be traditional metaphysics with a vengeance. And it points to another paradox in the *Tractatus*. Not only do its sentences condemn themselves to meaninglessness; its radically anti-metaphysical doctrines rest on a view of language which evidently has deeply metaphysical underpinnings.

While none of this concerned Wittgenstein much when he wrote the *Tractatus,* his later thoughts—largely products of work done in the 1930s and 1940s after his return to philosophy—explicitly reject these features of his early work. Specifically, his definitive later work, the *Philosophical Investigations,* takes care to show that its remarks on language, far from undermining themselves, apply straightforwardly to its own sentences. It exposes the metaphysical underpinnings of the *Tractatus* and rejects them as pathology of thought. While still insisting that metaphysics is senseless, the *Investigations* takes a somewhat more sympathetic view. It denies that metaphysical pronouncements, which seem to capture deep features of reality itself, actually succeed in doing so; but it allows that such statements, stripped of such pretensions, and seen in the right light, can succeed in calling attention to important features *of language*. Wittgenstein believed that the metaphysician was deceived by language itself and confused truths about words —'grammatical truths' in his terminology—with truths about the world. Wittgenstein devotes a great deal of effort to making these claims.

It is interesting that Carnap, perhaps the Vienna Circle's most enduring figure, working independently of Wittgenstein, developed a similar view of metaphysics in his more mature work. He argues, in *Logical Syntax of Language* published in 1937, that a major source of metaphysical pseudo-statements concerns a tendency to express syntactical distinctions in what he called 'the material mode of speech' rather than the more appropriate 'formal mode' [3.7]. Where for Wittgenstein, metaphysics was misconstrued 'grammar'; for Carnap, it was misconstrued syntax. The two views are closely aligned. Both philosophers emphasized that truths about words were confused with truths about the world and both tried to identify the source of such confusion in language. Their views, while sharing continuities with those of the *Tractatus* and the early positivist tracts, show greater sophistication. They are expressed in works that are more attentive to the origins of metaphysics in details of linguistic confusion, more willing to grant to metaphysicians a measure of insight, albeit confused, more self-reflectively constrained and more attuned to connections among logic, meaning and context. It might be said that the work of some leading philosophers of the second half of the century who have allowed themselves to discuss issues relating to ontology, modality, realism and essentialism—Quine, Ayer, Goodman, Strawson, Kripke, Dummett, Putnam and others—is carried out in a recognizably similar spirit.

As such, metaphysics has re-emerged in some measure, but in a form that recognizes, as a matter of course, constraints that would have been anathema to Hegel, Bradley or McTaggart. These constraints can be viewed as the legacy of the great philosophical figures discussed in this essay. The most notable of these connects with a new philosophical consensus concerning the relationship between philosophy and science. The absolute idealists, less than one hundred years ago, were willing to express metaphysical views clearly incompatible with the most basic views of modern science. Those philosophers of today still willing to engage in metaphysics, do so, almost unanimously, while rejecting any notion that it can produce substantive results that can add to—much less supersede—those of the sciences. This attitude, perhaps, reflects a more global cultural shift: one in which the approved methods for finding substantive truths about the world, its structure and its components simply are those of the sciences. Metaphysics, on such an assumption, can add

nothing to this; it must be satisfied with a meaningful but secondary role of interpretation, clarification or proper conceptualization.

CHAPTER 4
Metaphysics II (1945 to the present)

Bernard Linsky

THE REDISCOVERY OF METAPHYSICS

Metaphysics in the analytic tradition since 1945 has been a sustained reaction to the anti-metaphysical position of logical positivism. In his *Logical Syntax of Language* (1937), Rudolf Carnap lists a number of philosophical problems and notions that arise from mistaking puzzling features of language for substantive questions about reality. The traditional theories of truth, realism, universals, essential properties, time, causation, and so on, the subject matter of metaphysics since Aristotle, are, he charges, all due to confusion of language in its ordinary use, in the 'material mode' and language that really is about language, the 'formal mode' of speech. They confuse trivial, or meaningless assertions about language with substantive claims about the world. Though positivism denied the meaningfulness of most traditional issues, in the very linguistic approach of that denial one can see a somewhat traditional nominalist position emerging. What followed in the 1930s and 1940s were developments in logic and the philosophy of science that vindicated some aspects of the traditional problems of truth and the nature of necessity, causality, space and time. Since 1945 there has been a steady process by which problems have come to be seen as meaningful (although perhaps primarily logical or empirical in nature) and then become subject to many of the sorts of theories that had been presented at various other times in the history of metaphysics. The story, then, is of the re-emergence of metaphysics, primarily a certain Aristotelian tradition in metaphysics. The role of modal notions of necessity and essence clearly indicate that origin. For the most part there has also been a relative lack of interest in the metaphysical questions of the Kantian tradition. Discussions of free will versus determinism, the nature and place of the self and of God in the natural world, have not been central. Rather, the emphasis has been on questions of ontology and the most general features of the natural world, time, space and matter. One Kantian issue that has come to the centre of discussion again is the problem of realism versus idealism, now formulated as realism versus 'anti-realism'.

This survey traces what seems to have been the main line of development of metaphysics in the English-speaking world, namely the mainstream of the analytic tradition. Metaphysics, more so than other fields of philosophy in this century, has been a field in which schools of thought have clearly distinguished themselves from that main stream. Pursuing metaphysics as an independent subject has been a rallying point for those opposed to analytic philosophy, seeing it as the heir to the anti-metaphysical stance of logical positivism. Inevitably, then, this survey will miss what many may well see as the centre of the real metaphysics done in this period. Peripheral or not, all these groups maintained their version of the classical issues in metaphysics and, during this period since 1945, have, to varying extents, contributed to the rediscovery of metaphysics.

Thomism, the philosophy of Saint Thomas Aquinas, has been a persisting and central part of philosophy as taught in Catholic institutions of higher education throughout the English-speaking world. The *Review of Metaphysics,* edited at the Catholic University of America (founded in 1947), has served to maintain what might be seen as the broader tradition in metaphysics, publishing essays in the Thomistic tradition, as well as papers on topics from the whole history of metaphysics, discussions of metaphysics in the continental tradition, as well as several classics of analytic metaphysics. The position of maintaining a minority tradition in metaphysics is also that of the students of 'process philosophy' following Charles Hartshorne and Paul Weiss in his inspiration by the later work of Alfred North Whitehead. Closer to the mainstream, but still a self-identified minority position has been that of Gustav Bergmann's students, who have maintained discussions of metaphysics in the realist tradition of Bertrand Russell's logical atomism from before World War I. They maintained an interest in classical issues of realism about universals and the nature of particulars which re-entered the centre of discussion with the revival of interest in universals in the late 1970s. Bergmann insisted that logical positivism had not destroyed metaphysics as a subject, but had rather contributed a method for the study of traditional issues. And, he claimed, it had come to traditional positions, nominalism, materialism or phenomenalism in different hands. These views are becoming the accepted view. Accompanying the re-emergence of metaphysics has been a growing self-conciousness, an awareness that many apparently 'semantic' issues in logic and philosophy of language had import for metaphysics and embodied traditional metaphysical positions.

NOMINALISM

Nelson Goodman's *The Structure of Appearance* appeared in 1951 although the Harvard doctoral thesis on which it is based was completed in 1940. It was essentially an analysis of and improvement on Carnap's *The Logical Structure of the World*. The project was to 'construct' the world of space, time and material objects from the basic experiences or *qualia* presented in sense. The underlying ontology is that of phenomenalism. Material objects are just collections of appearances. The subject matter of the theory is experience, conceived as composed of individual items with sensory qualities, units of perception of colour and sound, etc. For Goodman the goal of a constructionist project is only to produce a reconstruction of a notion which is *extensionally isomorphic* to the pre-theoretic original. Isomorphism requires only the sameness of structure as represented in extensional logic, objects and relations which mimic the original. These constructions were to be effected with only the apparatus of *mereology* the 'calculus of individuals' originally developed by the Polish logician Lesniewski in the 1920s. That calculus is axiomatized by Goodman using only the one primitive first-order relation of 'overlap'. The *mereological sum* of individuals is another individual, importantly of the same logical type as its parts. For Goodman the characterizing feature of nominalism is that it does not involve commitment to any abstract objects such as sets or intensional entities, just objects and their sums. Logical type is the test of ontological category for Goodman.

While metaphysicians in this period have been reluctant to accept other categories of objects, in particular resisting any abstract entities other than sets, a generous ontology of particulars (assumed to be material, or at least physical) has been a general starting point. Every collection of objects and parts of objects forms a sum which has as its parts precisely those objects. Thus there is an object consisting of my hand, that book and the city of London. It has been seen as a problem to be solved, just what it is that distinguishes what we think of ordinarily as objects. Are they just those mereological sums that are of importance or interest to us? The problem of how and why we 'individuate' objects as we do, immediately comes to the fore, not as in earlier times as an epistemological question of our identifying and perhaps synthesizing objects from a stream of experience, but rather a question of explaining which of the many

existing mereological sums are in fact those that are important to us. The 'construction' of the Carnap-Goodman project does not create objects, rather it reconstructs our conceptual scheme and those objects that are important to us from a few primitive psychological notions, such as perceived similarity, thus explaining what it is that we select for our interests from the huge pre-existing ontology of the 'external' world of phenomena. The division of the world into objects and those in turn into kinds based on shared properties is all seen as in some way arbitrary, not 'real'. This form of nominalism, is, then, allied to anti-realism.

Goodman's account of qualities, or universals, illustrates the central role which mereology plays in his constructive project. Carnap had followed the nominalist strategy of constructing qualities as classes of individuals similar in the right way to each other. Roughly, a quality like blue is just a class of things similar to each other, the class of all blue things. Membership is determined not by possession of the same universal colour, but rather by greater similarity with other members of the class than with things outside the class. The class is the only general object, the one having many members as its 'instances'. This led, however, to the problem of 'imperfect community'. It is not possible to define a property as a class of objects more similar to each other than to anything outside the class as, for example, a red rubber ball, a blue wooden ball and a red wooden cube might resemble each other more closely than other objects such as some other red or wooden things, or balls, without sharing any real property in common. Goodman's solution is this: by treating mereological sums as individuals, they become possible candidates for the similarity relation. It is the mereological sum of individuals, not the individuals separately, which another must resemble to have the quality they share. Thus while taken pairwise the objects in the group may resemble each other strongly, the mereological sum of the group does not have the uniformity necessary to be similar to other objects whether red, wooden or balls.

Another feature of Goodman's nominalism which became more important in his later thought is the emphasis on predicates as the only general or universal entities. Thus 'green' is as good a predicate, and hence as good a property as his famous invented predicate, 'grue' (being observed before 2000 AD and green, otherwise blue). This leads to problems in epistemology when it is asked why inductions on actual emeralds, all of which are both green and grue, can lead to opposite predictions about emeralds inspected after the year 2000? Still later this nominalism leads to Goodman's version of anti-realism. To use his example, if predicates such as 'stereo system' are human contrivances, carving up the world according to our human interests and so mind-dependent, then so is 'star', and hence stars are every bit as much mind-dependent.

Goodman's nominalism influenced both his senior colleague Quine and the whole generation of metaphysicians trained at Harvard University, even if it was principally by contrast with the austere ontology of their teacher that positions were defined.

IDENTITY AND INDIVIDUATION

The 'ordinary-language philosophy' centred at Oxford and flourishing after 1945 and through the 1950s, tried to find in the study of ordinary language the resolution of traditional philosophical problems by diagnosing and eliminating some confusion underlying them. In practice it continued the hostility of logical positivism towards metaphysics. Thus David Pears' article, 'Universals' (1951), proposed an almost psychoanalytic account of the search for universals to underpin or explain the use of predicates [4.16]. Universals are shadows of predicates and the search is for an explanation where none is to be found. What do all red things have in common? Well, they are red. What more could be needed or provided as an explanation? We can explain what particular things have in common in different ways, but not what is common to all cases of similar objects. The problem of universals is not to give an account of some sort of

entity which performs a certain theoretical function, but rather to provide a cure for the desire to find such entities. While Renford Bambrough's 'Universals and Family Resemblances' (1960) ostensibly grants that there is a problem of universals, it finds the solution to the problem in Wittgenstein's notion of family resemblance, a solution that in effect denies the assumption of the problem that there is some one thing in common to the instances of a general term for which we need an account.

Not all discussions of metaphysical topics were so dismissive of the purported problems. Max Black's article 'The Identity of Indiscernibles' (1952) presented the thesis that no two objects could have all the same properties as quite clearly meaningful, but just as clearly false [4.5]. He suggested that one could easily imagine a universe consisting of two metal indiscernible metal spheres, and nothing else. Black introduced the approach of the ordinary-language school in analysing attempts to argue against his counter-example. Repeatedly it appears that we cannot insist that certain words have meaning, that we can, for example, succeed in referring to one sphere rather than another, just by having certain thoughts. We must show that such thoughts are not just pictures that lead us astray. We must remember the public and objective nature of the referring process in language by which things get their names. For example, we cannot name the spheres in the story, since, by hypothesis, no one exists in the universe to give them names. Black's article raised issues of the connection between the particularity of objects and of the preconditions for identifying and naming objects that was central to the metaphysical discussions of the next years, including in the work of Strawson.

Peter F.Strawson, with *Individuals; An Essay in Descriptive Metaphysics* (1959), moved away from the the anti-metaphysical tradition of the logical positivists as it had been continued by the ordinary-language movement [4.23]. Strawson called his project 'descriptive metaphysics'. His goal was to unearth the metaphysical scheme of our ordinary, non-scientific view of the world, to be found embedded in our ordinary language. Thus moving from the basic speech acts of referring and describing which correspond with the subject-predicate structure of our language, Strawson attributed a basic conceptual scheme composed of objects located in space and time with their qualities. The ability to use names requires 'identifying' and then 're-identifying' their referents at another time and thus the presupposition of a framework of enduring spatial objects within which such identification could proceed. Questions of ontological dependence are replaced by issues of conceptual priority. We do not ask whether space is absolute, or whether spatial relations depend on objects. Rather the question becomes whether a spatial framework is necessary for re-identifying objects. That may be so, if indeed we can only re-identify objects by tracing them through space from one time to another. Strawson devotes a chapter to investigating the intelligibility of a 'sound world' in which we only perceive sounds of different pitches in a temporal sequence.

Strawson's view of universals is a combination of conceptualist and nominalist elements. The concept of universal or property results from considering predication to 'introduce' an entity much as reference does. The entity is identified by the concept which we associate with the predicate. Strawson's interest was not with the ontological status of what is introduced by predicates as much as in the asymmetry between referring and predicating. He was concerned with the difference in category between objects and predicates. Objects can only be introduced by referring expressions, whereas predicated entities can also be referred to. Strawson argued that the asymmetry of logical role is not due to a difference in kinds of entities involved, but rather our talk of kinds of entities is a reflection of the prior differences in logical role. The difference between particulars and universals reflects the difference between referring and predicating. Strawson was also concerned with the conceptual relations between general qualities and particulars. What is the process of 'individuation' by which talk of a property being instantiated is replaced by talk of individuals? Here Strawson disagreed with Quine who considers the very same problem. Strawson argued that a language that

merely 'places' features at various locations, saying that there is snow or water in such and such a place, can only be an artificial one, and must depend on a prior conceptual scheme in which places are identified by objects that occupy them and features are the properties of those objects. Our ordinary scheme of objects with their properties located in space and time is conceptually prior to others that might be proposed as scientific or less ontologically laden.

In addition to material particulars, Strawson presented persons as an equally fundamental ontological category. The traditional problem of relating the mind to the body is resolved by seeing persons as a fundamental conceptual and hence ontological category, to which we attribute both mental and physical predicates. It is the person which both thinks and has material properties. This view has come to be known as 'property' dualism, as it avoids the familiar dualism of substance and is a forerunner of contemporary functionalism in the philosophy of mind.

Strawson's influence continued with David Wiggins who introduced versions of Aristotelian notions of natural kind and essential property using the Strawsonian framework of notions of identification and conceptual dependence. Those properties that we rely on to make sense of claims of identity through time, to 're-identify' the same object later, are candidates for essential properties, those properties an object could not but have had. This leads to a conceptualist account of modal notions. Properties are essential to objects because they underlie our conceptual framework. We could not have useful concepts for certain objects unless we attribute to them, that is, see them as having, certain essential properties. This move to attributing ontological significance to the preconditions of reference or use of language had led to a dispute over the notion of 'relative identity'. It has been argued that we only make sense of claims that one thing is the same as another relative to a category; something is the same statue or the same lump of bronze, not merely the same 'thing'. The view that we can always supply a 'sortal' term to supplement identity claims and that they seem incomplete otherwise has led some to the thesis that the relation of identity itself is relativized to such sortals. This in turn has led to an investigation of the nature of personal identity, those conditions under which we would say that one is the same person as someone before.

Contemporary treatment of the problem of identity started with examples from Locke of the same soul animating different bodies over time and went on to discuss science fiction scenarios involving such things as brain duplication and matter transfer. Work on these puzzles led to a widespread interest in the self and an awakening to the importance of the concept of personal identity. If one argues that the present self is not strictly identical with the later one, what is the rationality of self-interested actions now when the later person will benefit? What happens to the notion of moral responsibility as well? The topic of 'personal identity' has also led to discussion of the seemingly perspectival nature of certain concepts. The very notions of self-interest, or self-knowledge, require that there is a difference between objects that from a third person, or detached point of view are the same. Aside from the fact that so-and-so has certain properties, what more is added to the belief or knowledge that *I* am so-and-so? It is by this route that metaphysical problems of the self and our place in the world have emerged out of the original interest in the simple relation of identity.

Willard van Orman Quine has developed a metaphysical theory as a part of his coherent philosophy of language and science, replacing Strawson's 'ordinary' conceptual scheme with the metaphysics of science. Like Strawson, his approach to metaphysics is to investigate the metaphysical view imputed by a certain conceptual or linguistic scheme, only in this case the scheme is that of science broadly construed, rather than that of ordinary language. At the beginning of his *Word and Object* we find: 'Entification begins at arm's length; the points of condensation in the primordial conceptual scheme are things glimpsed, not glimpses' ([4.20], 1). Objects are the result of 'entification', as much our doing as really there. Quine openly sees ontology as something that is imputed by a theory which can at the same time be seen as chosen for various

seemingly subjective reasons. We select the simplest theory, the one which requires minimum revision to our previous theory, and so on, fully realizing that this may not be leading us to how things 'really are'. That he sees as a remnant of the 'transcendental' metaphysics that logical positivism overthrew.

Quine assumes the ontology of science, which he sees as that of a single, four-dimensional distribution of matter across points of space-time, and the language of science, the language of first-order logic enriched with predicates for both theoretical and observational terms. Quine's commitment to the language of first-order logic as a starting point in metaphysics has various consequences. One is Quine's test for the ontological commitment of a theory. A theory is committed to those objects that are quantified over in its statements. In his influential article 'On What There Is' [4.19], Quine criticizes Meinong's theory of objects which holds that even Pegasus must have some sort of being in order to be an object of thought. Quine responds that this is a mistake, based on that fallacious assumption that names must refer to something in order to be meaningful. The meaning of names, like that of definite descriptions, such as 'the tallest mountain', are given by expressions of logic that do not depend for their meaning on having a referent. One can meaningfully deny 'The winged horse exists' without there having to be a winged horse. That is because the sentence only involves predicates and quantifiers. It says, roughly, that there is some winged horse (and at most one winged horse). That sentence is simply false. True sentences with names or descriptions in them only commit one to the objects that the resulting quantifiers and their variables range over. Statements such as 'Some quarks have up spin', when regimented as 'There exists an x such that x is a quark and x has up spin', is seen clearly to commit us to quarks. This results from the view that variables are the genuinely referring devices in a language, names being eliminable in terms of definite descriptions and those in turn eliminable via Russell's theory of descriptions. Bound variables, such as the x above are said to 'range over' certain objects, and the commitment of the theory to them is determined by that quantification alone. Quine's slogan is: 'To be is to be the value of a bound variable'.

There are several immediate consequences of this simple doctrine. Any such notion as Meinong's distinction between entities with being as objects of thought, and those that exist, is ruled out. 'Everything exists' is a simple theorem of logic when read as 'Everything is identical with something', yet it has ontological consequences. There is no realm of non-existent or merely possible beings. Second, no other part of language besides bound variables will produce any ontological commitment. Quantification is the only way a theory commits one to objects. The use of predicates does not commit one to the existence of universals. Quine is quite openly nominalistic about predication. A predicate is simply 'true of' its many instances. They do not have to have any *thing* in common, any universal. To be a man, Quine says, is just to be such that one's name with the predicate 'is a man' produces a true sentence. It is that which all men have in common. As the thesis that what is general is only a general term, this is a classic statement of nominalism. Quine himself followed Goodman's slightly different definition by which any acceptance of abstract entities, even particulars such as sets, is a move away from nominalism and towards Platonism. The seemingly unavoidable use of mathematics, and thus of the set theory to which it is reduced, within science led Quine to take the variables of set theory at face value as ranging over sets, objects differing from the individuals of Goodman's mereology.

Quine's criterion for deciding to make an ontological commitment is the pragmatic test of the needs of 'science' for the proposed entities. Does the simplest, most comprehensive theory of the phenomena quantify over entities? If so, then adopt the theory and accept the accompanying ontological commitment. Simplicity and fruitfulness are pragmatic criteria. It is easy to see why one might make use of such theories, but it is not obvious, to a realist, why they make a theory more likely to be true. Quine's philosophy is thus following in the Harvard pragmatist tradition of James and Peirce. Truth is to be explained, or at least judged on pragmatic grounds. For making an ontological commitment Quine defers to science, but in

practice he argued against certain entities on more *a priori* grounds. Science, and common sense, require that theoretical entities be well defined. Quine's primary test for recognizing entities, came to be the easy statement of 'identity conditions'. The model answers are provided for material objects, which are the same if they occupy the same spatio-temporal locations, and sets; sets x and y are the same if and only if the members of x are exactly the members of y. This condition does not define identity for the objects in question, since it takes the notion of identity as primitive, nor does it describe how to 'identify' entities, as in Strawson's notion. It is simply a thesis of the theory of sets, one which gives necessary and sufficient conditions for the identity of sets. The lack of such identity conditions was used by Quine as a complaint about universals and other 'intensional' entities such as propositions and possible objects. 'No entity without identity' is the slogan for this aspect of Quine's metaphysics. Between the quantifiers and identity we have all of the conceptual apparatus that Quine needs. Where Strawson was concerned about the dependency of our notion of object on a framework of space and time, Quine speculates about the emergence of the notion of individual when mass terms such as 'water' get supplemented with the use of identity to produce individuals. Thus at some point a child's notion of 'mama around' is replaced by the notion of a persisting object, her mother, that is distinct from others. Time is not a framework in which objects are identified and re-identified, but rather a dimension along which the temporal parts of objects can be located. For an object to be red at one time and green (thus not red) at another, requires that the object have distinct parts, one of which is located 'at' the first time and is red, and the other of which is 'at' the second and which is green. The relation between the two is not identity, rather they are parts of a particular mereological sum which is identified as an object.

That the language of science is the guide to ontology has consequences when Quine considers that the truth-conditions for sentences and the range of quantifiers are only stated in a background metalanguage. This leads to the doctrine of ontological relativity: the thesis that one can only specify the ontological commitment of a theory in the terminology of another theory and that different such accounts can be equally justified. Indeed very distinct background theories and assignments can agree on the truth of all sentences in the object theory. Quine gives this example: an account of a language which interprets the term *gavagai* as true of rabbits which is as empirically adequate as one that interprets the term as true of undetached rabbit parts. There is thus a slack that can be taken up in different ways, producing incompatible accounts of ontological commitment, and giving an ineliminable relativity to claims about ontology. There is not a fact of the matter about our ontological commitment, except as it is revealed by a particular choice of meta-language and theory. When we are studying our own ontology this meta-language is an extension of our own object language. While 'There are quarks with up spin' commits us to quarks, there is no theory-neutral way to explain what that commitment amounts to. Quine presents this as an aspect of the pragmatist element in his thinking. We work inside a conceptual scheme, or theory, trying to improve it as we go, but, in the image he takes from Otto Neurath, like sailors in a ship who must rebuild at sea. We make the best of the theory we have and do not strive for some external, God's-eye view from which to assess our knowledge. This doctrine of ontological relativity and the accompanying view of our attitude towards our own ontology was later taken up by anti-realists.

Donald Davidson proposed the study of the ontological commitments of a meta-language as a method for metaphysics. Davidson argued that a theory of truth, in the form proposed by Tarski, is not only an approach to an account of meaning for a language, but also a guide to its ontology. Following Quine, he agreed that the ontological commitment of a theory is determined by the range of its quantifiers, but then went on to suggest that quantification could be found in contexts where it is not on the surface. Thus Davidson argued for the recognition of *events* in our ontology on the grounds that a proper account of inferences of certain sentences about actions requires them to be treated as quantifying over events. A

theory of truth must account for logical inferences in a language and so one may go from knowledge of inferences to a theory of truth that would justify them and that may reveal hidden ontological commitments. Thus, one may infer from 'Jones buttered the toast in the bathroom with a knife at midnight' that 'Jones buttered the toast in the bathroom with a knife', 'Jones buttered the toast in the bathroom', 'Jones buttered the toast', and more. The ordinary formulation of such sentences in first-order logic, using a relational expression '*x* buttered *y* in *z* with *w* at *t*', will not permit such inferences. Only a formulation with explicit quantification over events will capture those inferences, he argued. One must treat the original as of the form 'There is an event *e* and *e* is a buttering and *e* is of the toast and *e* is by Jones and *e* is in the bathroom and *e* is at midnight' which permits the inference to the other sentences, easily, once they are seen to be of the forms 'there is an event *e* and is a buttering and *e* is of the toast' for example. Putting sentences into a logical form in first-order logic, because it is necessary for giving a theory of truth for a language, becomes in turn a method in metaphysics, the 'method of truth in metaphysics'.

Quine had identified events simply as classes of points in space-time, thus seeing ordinary objects as simply enduring events (those oriented along the time axis in space-time). Davidson felt required to postulate them as *sui generis* entities, since it appears that two distinct events can occupy the same space at the same time. He suggested the example of a sphere slowly rotating and growing warm at the same time. It seems that there are two events occurring together, the rotating of the sphere and its warming. If not spatio-temporal location, then what are the identity conditions for events? Several rival accounts have been proposed, usually involving reducing events further to some other category, usually to combinations of objects and properties. Perhaps the two events are distinguished by the different properties they involve, growing warm and moving around an axis. Davidson, with the same nominalist inclinations as Quine, would have none of that. Rather, he suggested, events are to be identified by their causes and effects, same causes and effects, same event, to mimic Quine's criterion for sets, same members same set. The criterion has struck most as quite different from Quine's and not as successful. The ensuing discussion of events was most fruitful for the theory of action, as well as reviving interest in events and related notions such as that of facts which had been absent from metaphysical discussions since the time of logical atomism.

Davidson's discussion of events was driven by the need to formulate event sentences in first-order logic. His and Quine's philosophy is deeply committed to the validity of first-order logic and its extensional nature as the proper language of science. Quine's purely technical objections to the logic of necessity (quantified modal logic) were accompanied, however, by the conviction that making sense of that logic would lead to unsavoury metaphysical involvements, the 'jungle of Aristotelian essentialism'. His opposition to modal logic was met as a challenge, by some of his own students, and so was perhaps the leading cause of a revival of the very Aristotelian metaphysics that he dreaded.

MODAL METAPHYSICS

Saul Kripke introduced a new era of metaphysical theorizing with his possible-world semantics in the early 1960s and particularly his lectures 'Naming and Necessity' given in 1970 at Princeton University. As part of his qualms about intensional notions, Quine had charged that quantifiers could not always be intelligibly combined with sentence operators such as 'It is necessary that'. Quine held that one might try to make sense of 'It is necessary that there exists some *x* such that *x* is *F*', what is called *de dicto* necessity, as some disguised claim about the sentence 'There exists an *x* such that *x* is *F*', perhaps one which claims it is an analytic truth or an axiom. This account is true to the etymology of 'dictum' as 'what is said'. The other combination, or relative scope for the quantifier and operator, as in 'There is an *x* such that it is necessary that *x* is *F*', leads to an assertion of *de re* necessity (necessity in the thing, *res*). Here it is at least one thing *x*

which is claimed to have a necessary property. This cannot be easily interpreted as an attribution of necessity to something that is said. Quine thought that interpreting such sentences would require a forced and arbitrary distinction between the properties of an object, those it has merely in virtue of how it is described and those it has of necessity, or essentially. To use the example which Quine favoured, a bicycling mathematician seems to be essentially two-legged when described as bicycling, and rational when described as a mathematician, but does not have one property more essentially than the other. Discriminating properties on such a subjective basis leads, Quine feared, to the hopeless confusions, or 'jungle' of Aristotelian essentialism, the logical positivist's equivalent of the early modern philosopher's horror of scholasticism.

Kripke's possible-world semantics provided a way of modelling such distinctions. A sentence is to be interpreted in terms of a class of possible worlds in addition to a distinguished *actual* world. For a sentence asserting necessarily p to be (simply) true (that is, true at the actual world), p must be true at all possible worlds. *De re* necessity is represented by seeing the worlds as each having a domains consisting of the objects existing at that world, domains which can overlap in membership. An object x is essentially F if it is F at every world in which it exists. The *de dicto* assertion above is taken as true if there is some object or other in each world which is F. For example (to modify one of Quine's famous examples) the *de dicto* claim 'Necessarily there is a shortest spy' is true because in each world some spy is shorter than all others. For the *de re* assertion to be true there must be one object that is F at all worlds in which it exists. Thus the clearly false *de re* claim 'Some spy is necessarily the shortest spy' requires that there be some one individual spy who is shorter than all other spies in all the worlds in which that spy exists. Much of recent modal metaphysics can be seen as an attempt to explore the metaphysical commitments and assumptions of this possible-world semantics.

With a way of making sense of *de re* necessity in hand, Kripke went on to make several claims about particular examples of *de re* necessary truths. One which has had a great impact in the philosophy of language has been the claim of the necessity of identity. One consequence of Kripke semantics is that for any x and y, if $x=y$ then necessarily $x=y$. This is compatible with the failure of substitutivity in modal contexts, the intensionality which is a defining characteristic of this logic. It may be that both a *de dicto* truth that:

It is not necessary that nine=the number of the planets

and a *de re* truth that:

Of the number of the planets (i.e. nine) and nine, it is necessarily the case that the former=the latter.

While definite descriptions do not pick out the same object in each world, and hence lead to apparently contingent identity claims, 'rigid designators' which do pick out the same object across worlds will appear in necessary identity statements. Thus, claimed Kripke, if 'Hesperus' and 'Phosphorus' are both names (for Venus) and hence rigid designators, then 'Hesperus=Phosphorus' is a necessary truth. Kripke presented this as an example of a necessary truth which is knowable only *a posteriori,* which runs against the traditional identification of the necessary with the *a priori*. While this abandonment of the traditional epistemology of necessity had a liberating effect on metaphysical speculation it has not been replaced by an agreed-upon alternative epistemological account.

Kripke's extension of his notion of rigid designator to natural-kind terms produced another class of candidate *de re* necessary truths. If general terms such as 'water', 'tiger' and 'H_2O' pick out natural kinds

rigidly, i.e. across possible worlds, then such claims as 'Water= H_2O' and 'Tigers are animals' may express necessary truths of the new class, *a posteriori, de re* necessities. A large debate has developed surrounding the essential properties of natural kinds and whether, in fact, such considerations from the philosophy of language about designation can have such substantive metaphysical consequences.

A second kind of *de re* necessity which Kripke explored was the essentiality of origin. He asserted that it is essential to an object to have the particular origin that it does. Origin is essential for artifacts as well as natural objects, thus a particular wooden lectern was necessarily originally composed of the particular wood from which it was in fact made, although it might later come to be made of different wood over time. (A modal version of the ship of Theseus was soon presented as a challenge to this. Suppose a material object could have been made of slightly different material from that which actually makes it up, say that a wooden ship could have had three or four planks different from those in actuality. But if that differently composed ship would still be the same ship then that different collection of planks could have varied even more, and so on, until, it seems, the ship could have been made of any collection of planks. As with identity through time, identifying objects 'across' worlds seems to be subject to puzzles.) Kripke's thesis also holds for natural objects, in particular people. If so, then a human being, such as Queen Elizabeth, essentially came from the particular egg and sperm from which she did arise. Other offspring of the same person would not have been Elizabeth, and a person even atom for atom like Elizabeth now, but having arisen from a different origin, would not have been the same person.

These theses about the essential properties of individuals and natural kinds have produced much contemporary debate as well as inspiring investigation of those figures in the history of philosophy who investigated modal notions, in particular the Aristotelian tradition. An immediate consequence was various attempts to apply Kripke's notion of natural kinds and essential properties to one prominent example of natural kinds, biological species. The 'species problem' in the philosophy of biology entered the mainstream of metaphysics and soon led to the rival thesis more in keeping with current evolutionary thinking that species are just classes of objects related to each by ancestry, or even best seen as single individuals, mereological sums of the ordinary organisms that belong to them.

Another consequence of Kripke's semantics has been a resurgence of interest in the ontological argument, and other theological issues such as the problem of divine foreknowledge. Alvin Plantinga has defended a modal version of the ontological argument. It is a simple axiom or theorem of modal logic that what is possibly necessary is in fact true. If it is part of God's nature to exist necessarily, from the mere possibility of God's existence we can infer His actual existence. This in turn has led him and many others to look at the epistemological status of modal claims of necessity and possibility, as they do appear as premises of many traditional arguments. Plantinga is one of a number of prominent modal metaphysicians who are also believers. Long thought by its religious detractors to be a part of the atheistic world-view of twentieth-century science, analytic metaphysics has now emerged as a tool for traditional theological speculation and philosophers have moved from the main technical questions of metaphysics to investigations of their own faith with relative ease. Traditional theological notions such as omnipotence, omniscience, atemporal existence, and predestination are all readily explained in modal terms with possible world semantics.

The interpretation of possibility and necessity using possible worlds has also led to a revival of interest in the notions of freedom and determinism. The model of the world as having a fixed, single past, but a branching structure of possible futures has liberated many from the seemingly deterministic metaphysics of natural science with its single space-time extending from past to future. This natural model of an indeterministic world has revived interest in the problem of free will, trying to reconcile the assumption of our freedom to act with the deeply entrenched belief that the world is governed by natural laws that have some sort of modal force. While the Quinean scientific world-view that dominated post-1945 analytic metaphysics gave

no special ontological status to natural laws, laws just being universal generalizations arrived at in the right way and with the appropriate epistemological status, it was still felt that being subject to laws was an appropriate analysis of the notion of determinism. To the extent that determinism had content, it was felt to be true. The introduction of possible-world semantics for talk of necessity changed that attitude. The problem of free will has re-emerged in full force.

Developing out of his alternative to Kripke's version of possible-world semantics, David Lewis has developed a complete metaphysical scheme culminating in his *On the Plurality of Worlds* [4.14]. Kripke's semantics makes sense of *de re* necessity by saying that an object *x* has a property *F* necessarily, just in case *x* has *F* at every possible world *w* at which *x* exists. Lewis's alternative counterpart theory holds that each object exists in only one world. When we say that *x* has *F* necessarily we mean that in each world *w,* the *counterpart* of *x* at *w* has the property *F*. Lewis has a surprisingly Quinean view about the reality of counterparts and the possible worlds that contain them. For Lewis possible worlds are spatio-temporally extended objects containing their members as mereological parts. The actual world is just 'me and my surroundings', the universe. Other possible worlds are just like this world, composed of material objects that exist every bit as much as the objects in the actual world. They are separated from this world only by lacking any spatial or temporal relations to objects in this world. Lewis's possible worlds look very much like the world on Quine's view, except there are many of them. Thus it is possible for him to identify properties with sets of objects, although objects drawn from many possible worlds. The property of redness, then, is the set of all red objects, including both the actual and all possible red objects. Using only Quine's physical objects and sets, Lewis is able to distinguish entities that Quine must identify. Lewis also shares Quine's view of the world as composed of objects extended in four dimensions, thus as with Quine, change is explained by different temporal parts of objects having different properties.

The seemingly small addition of what look like many additional versions of Quine's universe of course has far-ranging consequences. Many of the modal notions banned from Quine's ontology are re-introduced by this simple expedient. In addition to the background notion of metaphysical necessity explained as truth at all possible worlds, Lewis is also able to account for more relative or restricted notions of necessity as in causal laws and counter-factual claims about what would have happened under certain circumstances. The basic notion underlying these analyses is Lewis's account of counter-factual conditionals. To say that 'if the match had been struck, it would have lighted' is to say that while the match may not have been struck in the actual world, in those worlds sufficiently similar to this world, but differing by having the match struck, the match also lights. The notion of similarity of possible worlds is taken by Lewis as a primitive for the analysis of a range of other notions. With an account of counter-factual conditionals in hand Lewis then analyses particular causal statements, as in 'the striking of the match caused it to light' in counter-factual terms. The match was struck and lighted, and if it had not been struck, it would not have lighted. Causal laws are then generalizations over actual and possible causal connections. With these analyses in hand, Lewis has ventured into some of the topics not common to recent metaphysics. Thus he can give an account of the traditional 'compatibilist' account of freedom of the will. It is possible for Lewis to give some detail to the account by which actions can be simultaneously caused and subject to natural law, and free in so far as they are caused by our desires and will. An action, however law-governed, is free in so far as had we chosen otherwise, we would have done otherwise. These analyses have also allowed Lewis to speculate more meaningfully about the notion of time-travel with its accompanying puzzles about causation and determination.

What of Quine's criterion of ontological commitment and his rejection of the Meinongian notion of objects that do not exist, but merely have being? Lewis fully accepts Quine's criterion of ontological commitment; all objects one quantifies over in a theory are commitments of the theory. Thus Lewis allows that talk of 'all

donkeys' ranges over not only the actual donkeys, but also the possible talking donkeys we are committed to by saying that possibly (i.e. in some possible world) there are talking donkeys. Unlike a Meinongian object, possible entities *(possibilia)* do not have a special status such as being which is distinct from, and somehow inferior to, existence. They exist every bit as much as real entities. But surely, it will be said, then Lewis believes that talking donkeys exist, but donkeys don't talk! Here Lewis replies that there are indeed talking donkeys, but no *actual* talking donkeys. That, however, does not mark a distinction of ontological category, for, according to Lewis, the term 'actual' is an indexical term like 'I' or 'here', meaning something like 'in the same world as the speaker' and so does not mark out a special category of thing any more than other indexicals do.

Lewis's counterpart theory, in particular the view that every object exists in only one world, is essential for this 'indexical' theory of actuality, and to his view that every world is just as real as the actual world: what has been dubbed his (extreme) modal realism. Worlds could not be Quinean universes if they contained ordinary objects having properties they do not actually have. Lewis argues for his counterpart theory, indeed, by finding it incoherent for an object to have different properties at different worlds. He formulates this as the 'problem of accidental intrinsics'. Consider, he says, some internal or non-relational property of an object which is not essential to it. It is hence accidental and intrinsic. Thus a person Hubert, who actually has five fingers on his hand, might have had six. Suppose we analyse this by saying that while Hubert has five fingers at the actual world *w** he, Hubert, has six fingers at some other world *w'*. But having a certain number of fingers is intrinsic to Hubert. What object has six fingers at *w'*? Hubert, who has five fingers. How can something which has five fingers have six? The reply that the notion of having a property at one world and not at another is primitive to modal metaphysics does not move Lewis. He finds that primitive notion incoherent. Lewis's view is in the minority. The more common view is that objects can exist in different possible worlds. One version of this is sometimes called *haecceitism* (echoing medieval discussions) to indicate that objects have a haecceity or 'thisness' which is independent of any properties they may have, and thus makes sense of existing in a world independent of the properties that are had at the world. Haecceitism is not the only view that supports cross-world entities. An alternative view is that objects can only exist across worlds in virtue of an 'individual essence' (echoing the older 'quiddity' or 'suchness') which provides their identity despite differing (perhaps intrinsic) properties in different worlds.

Both Lewis's notion of actuality and the debate over counterpart theory have led to a growing interest in medieval views of notions of existence, identity and individual essences among modal metaphysicians.

MEINONGIANISM

Consideration of the notions of actuality and of the status of *possibilia* has led to new interest in the object theory of Alexius Meinong and his students which was so intertwined with Russell's theory of descriptions and the rise of analytic philosophy. Although developed originally as a logical theory making sense of non-referring names like 'Pegasus' and the contradictions surrounding postulating 'round squares', some developments of Meinongianism are more explicitly metaphysical. All accept the distinction between being and existence. There is a wide domain of entities with being, such as round squares and golden mountains, only some of which have the property of existence. Terence Parsons in *Nonexistent Objects* [4.15] distinguishes ordinary nuclear properties such as colour and physical properties from special extra-nuclear properties such as existence and other categorical properties such as being an object, and so on. This distinction allows him to reconcile the Meinongian drive to postulate as many entities with being as possible, without engendering contradiction. We cannot define into existence the 'existent golden mountain' because existence is extra-nuclear. Still, 'the golden mountain' will have being. Parsons'

Meinongian metaphysics is directed primarily at providing an ontology for the semantics of natural languages, where reference to the non-existent is ubiquitous. Parsons counts fictional objects, characters in fiction such as Sherlock Holmes and Hamlet among his non-existent entities. They are typical incomplete Meinongian objects; while Sherlock Holmes had an address and a famous costume, he neither had nor lacked a mole on the heel of his left foot. Fictional characters only have the properties attributed to them in the story, or which follow closely from those attributed. Parsons' work, and related work on what is known as the 'logic of fiction' has drawn considerable interest within literary theory, and is a point at which the disciplinary isolation of much of recent analytic philosophy is breaking down.

Edward Zalta's *Abstract Objects* [4.26] is more explicitly metaphysical, developing a theory of objects in which other metaphysical notions of possible world, monad, universal and more can be modelled. His basic notion, derived from Ernst Mally, a student of Meinong, is to distinguish two modes of predications, inherence and encoding. While ordinary properties inhere in concrete objects, abstract objects, both more traditional ones such as sets and universals, and the new Meinongian round squares, rather encode those properties. While explicitly metaphysical in nature, Zalta's system lends itself to formalization and promises what he terms 'axiomatic metaphysics', allowing the derivations of theories of objects such as possible worlds and intentional objects from a small list of basic axioms. As with the modal metaphysics of Kripke and Lewis, Meinongianism began as a theory of interest to logic and formal semantics, but is taking on a life of its own as a metaphysical programme.

NATURALISM

The orientation of logical positivism towards natural science, and in particular physics as the model of a science, combined with the positivist doctrine of the 'unity of the sciences', has led to a strong tradition of naturalism in recent metaphysics. In the work of Quine, for example, it is clear that the methods and theories of science are continuous with respect to those of common sense, but refined and self-conscious, and therefore to be given a privileged status. The doctrine of the unity of the sciences and the principle of the reducibility of all sciences ultimately to physics give the ontology of physics a privileged position for Quine. That ontology is composed of points of space-time bearing familiar physical, material, properties of mass and energy states, and so on. For Quine, the needs and current theories of physics are the arbiters of ontological commitment. Hartry Field and others have found Quine's commitment to sets as out of keeping with the physicalism of the ontology of science and thus see as a fundamental project that of clearing science of any apparent commitment to such abstract objects.

David M.Armstrong, and a school of Australian philosophers influenced by him, have found that a commitment to universals is compatible with that overriding physicalism. Armstrong's *Universals and Scientific Realism* (1978) has led to a wide-ranging discussion of realism about universals in connection with natural laws, induction and causation within the philosophy of science, as well as in metaphysics. He characterizes his own 'world-hypothesis' with the following three theses '(1) The world contains nothing but particulars having properties and related to one another (2) The world is nothing but a single spatio-temporal system and (3) The world is completely described in terms of (completed) physics' ([4.1], 126) He argues that universals are not to be postulated to explain the appearances of language, in particular the nature of predication, but rather to be introduced on the purely scientific basis of being theoretical entities required to explain the observed phenomena. In the case of universals the phenomenon is exact similarity. This is best explained as the result of an identity. The very same universal is present in the various exactly similar instances. Armstrong's realism avoids what he sees as the major non-physicalist feature of Platonic realism by arguing that universals are spatio-temporally located in their instances and not in some Platonic

realm. This 'immanent' realism which Armstrong cites as Aristotelian in tradition rather than Platonic, has the result that universals can exist only when instantiated. By individuating universals via their connection with causal powers, Armstrong also has reason to question the existence of higher-order universals, properties of properties. Only objects subject to causal influences can possess the properties that explain that causation.

Universals are central to Armstrong's account of natural laws. Breaking with the long-standing empiricist tradition of holding a regularity theory of laws, Armstrong holds that laws are due to relations between universals. While there may be all sorts of constant regularities in the world, what makes most 'accidental' is that they are not due to a relation between the universals involved, rather just their co-extensiveness. It is this primitive relation of necessitating that is what is added to that mere coincidence when one really has a law. This marks a quite dramatic change from all the metaphysicians of this period. Quine certainly subscribes to a regularity theory of law, finding what distinguishes laws from mere accidental regularities in the special role of statements of law in our theories. Even Lewis reduces necessity, causal or otherwise, to a regularity over all possible, or all physically possible worlds.

Causal relations play a central role in other parts of Armstrong's systematic philosophy, including his accounts of epistemological notions such as perception and knowledge. Armstrong defends an 'externalist' account of epistemic justification by which the evidential properties of sensory experience, for example, derive from their being reliably related to certain external evidence via systematic causal relations. Armstrong's physicalism has also been influential in the philosophy of mind via his *A Materialist Theory of Mind* (1968) which advocated what has come to be known as 'reductive materialism' [4.2]. That position holds that mental states such as pain, belief, self-consciousness are all identical with certain states of the brain or central nervous system. Just as science has identified lightning with the discharge of electricity, or water with H_2O, it is the chore of science to find the right physical states with which to identify mental states. The model of ontological commitment for Armstrong, as for all physicalists, has been the reductions and identifications provided by the natural sciences.

Wilfred Sellars' distinction between the *manifest* and *scientific images,* the world of macroscopic, continuous, coloured, etc., objects, and the world of sub-atomic particles and no secondary qualities, has inspired a range of attitudes towards naturalism in response. The eliminative materialism of the philosophy of mind, which dismisses the manifest image as 'folk psychology' on a par with talk of phlogiston and witches, advocates revising our ordinary notions and adopting the scientific image of the world as our ordinary conception. Those notions that do not fit in well with naturalism, then, those that resist reduction, are simply to be abandoned. This extreme naturalism is charged with being an overvaluing of science, a scientism. It also leads to certain forms of anti-realism.

ANTI-REALISM

The various forms of naturalism and physicalism discussed above all shared in reaction to classical logical positivism a realism about the theoretical objects of science. That realism was extended to a general realism by Hilary Putnam in conjunction with the theory of natural-kind terms developing with the causal theory of reference. The idea was that all terms, including theoretical terms that were once to be given operationalist or empirical meanings, in fact get their reference by causal connection with an object or kind or property in the world.

In two addresses in 1976 and 1977, Putnam quite dramatically announced his abandonment of realism, soon to be followed by a number of other prominent philosophers. The 'anti-realism' that is to replace realism takes different forms, but uniting them all is an abandonment of the simple picture of reference and

of realism about theoretical terms that went with it. Putnam relied originally on semantic arguments, familiar facts from logic about the possibility of many alternative models or interpretations of a given theory. Realism, Putnam charged, relies on there being one distinguished interpretation which stands out from the others. But any theory of what that relationship is is just that, 'more theory' itself subject to radically different interpretations. That one may well have a notion of reference 'within' a theory, as a causal, or other ordinary relation between words and things in the world, Putnam allows, as long as this is an 'internal' realism. Thus, for example, the realism of science towards its own entities may be seen as a legitimate scientific hypothesis and understandable as an internal, or theory-dependent sort of realism. But if one tries to assert that science as a whole, or our language as a whole, is true because of correspondence with an independent reality, then one has entered into the incoherent 'metaphysical' realism that his arguments attack. This realism is thus not a view about the existence of particular entities, but rather a global view about the nature of truth. Putnam characterizes metaphysical realism by the view that truth is radically non-epistemic, that all our justified beliefs could turn out to be false. He has introduced the vivid 'brain in a vat' hypothesis (to echo Descartes's 'evil genius') to make this position clear. Might we just be brains kept alive in a vat of nutrient solution by a mad scientist? Thus all our ordinary beliefs about ourselves and our bodies would be false, however well justified by the carefully designed sensory input we are given. No, Putnam says, the very notions of belief and reference do not allow for such a possibility. We cannot so separate out the content of our beliefs and their objects. Nor can we make sense of a notion of truth so divorced from our beliefs. Instead, Putnam has advocated a more pragmatic notion of truth, one tied more to our epistemological practices and standards. He has argued that abandoning the realist picture allows a reconciliation of the dichotomies of fact and value, natural and interpretive social science, that have plagued western culture.

Michael Dummett had argued since the 1950s for the application of notions from intuitionistic mathematics more generally in philosophy, in particular the intuitionist notion of truth as similar to the notion of proof or of what has been verified. That attitude, which makes it possible for statements to be neither true (verified) nor false (shown false), and the consequent truth-value gaps, he termed 'anti-realism'. This version of anti-realism can be seen as coming close to a return to the sort of verificationism with which positivism began. As with Putnam, Dummett's anti-realism centres on the notion of truth. Dummett's emphasis, however, is on the theory of meaning that might allow for a realist theory of truth. Basing his arguments on the views of Wittgenstein about the public nature of meaning, Dummett has argued that meaning must be such that grasping of meaning can be publicly demonstrated and verified. But how, he asks, could anyone demonstrate a grasp of truth-conditions if these are independent of verification? We can either grasp the meanings of terms directly in terms of the conditions for verifying sentences in which they occur, or indirectly via their connections with terms that can be so understood. There is no way to give meaning to terms that run beyond possible verification. As a result, claims about domains which are 'verification-transcendent' are neither true nor false. Intuitionists argue that while many elementary claims about numbers can be verified, others, including many that involve quantification over all numbers, are not verifiable. The famous intuitionist example is the claim that there is a series of seven consecutive sevens in the decimal expansion of . The assertion that such a statement nevertheless has a definite truth-value presupposes a 'God's-eye view' of the infinite series of digits in the expansion, something that runs beyond any human capacity and hence is not true or false. Dummett extends these notions throughout our language by comparing the class of decidable sentences about numbers with those verifiable claims about objects about which we are 'realists' in contrast with those realms where verification is impossible and about which we must be 'anti-realist'. The telltale logical distinction is that we accept the law of the excluded middle for statements about ordinary physical objects and others about which we are realists, but are not entitled to that

when we go outside that realm, talking of the past which is no longer accessible to verification, or to use another example, when we speak of dispositional character traits, such as bravery, of those who are gone, and no longer able to manifest such traits. This anti-realism could be limited to certain realms and aspects of our discourse or of the world it is taken to describe, although recently followers of Dummett have argued for a more global anti-realism, arguing that no class of statements is conclusively decidable. Dummett's emphasis on the theory of meaning and his reliance on Wittgensteinian arguments to ground his anti-realism has meant that fewer connections have been drawn between it and traditional issues in metaphysics, in particular the traditions of German idealism and American pragmatism.

Other sorts of anti-realism are less verificationist. Bas van Fraassen in his *The Scientific Image* (1980) advocates an anti-realist view in science that allows full meaningfulness to statements about theoretical entities that range beyond what is established by the empirical evidence [4.24]. While fully meaningful, van Fraassen claims, the truth of such statements is simply not a concern of science. Science aims at empirical adequacy, theories aim only at being able to predict observations correctly, and that they can do even if it is only as if they were true. (Van Fraassen consciously echoes Vaihinger's 'philosophy of as if', in contrast with the positivism of the late nineteenth century when presenting his views.) Science can be agnostic about the truth of sentences about theoretical entities while granting that those assertions do have a truth-value. This is a much less global anti-realism than those of Putnam and Dummett. In fact, some identify it as a 'scientific' anti-realism, or identify it by van Fraassen's term 'constructive empiricism' and see it as independent of the issue of 'metaphysical' realism. It does, for example, contrast the status of theoretical entities such as electrons with that of the instruments and apparatus with which they are studied. In addition, the classical correspondence notion of truth (explained in terms of logicians' 'models') is held to make sense, but just not to be the object or goal of science. While van Fraassen is primarily considered a philosopher of science, it is unclear, however, why his view should not be taken as a stand on the nature of 'metaphysical' realism, much as Vaihinger's philosophy was. It is in the nineteenth-century positivist tradition that verifiable human knowledge (in science, but what other sort is there for heirs of logical positivism?) must be limited to the phenomena. Like Vaihinger, van Fraassen holds that statements of 'metaphysics', which go beyond the phenomena are meaningful, and can be accepted on other grounds, such as revelation or faith. The echoes here are of the Kantian distinction between the phenomenal and noumenal realms and it certainly seems to be an approach to the 'metaphysical' problem of realism.

Richard Rorty [4.22] challenges the metaphor of the mind as a mirror of nature which underlies these concerns about the truth of theoretical statements in contrast to the evidence that we have for them. This characterization of realism identifies it closely with the correspondence theory of truth, as earlier idealist critics of realism had also done. The 'problem of truth' has returned from the field of semantics to metaphysics where it was discussed in the nineteenth century. Rorty claims that the problem of realism will dissolve when we see that it is based on a faulty metaphor of the mind as a medium which reflects a world to which it does not belong. Only with this image in place are we able to ask questions about what represents the world and what is represented and whether there is a 'real' world 'behind' those representations. While rejecting the very notion of a world going beyond the evidence which is adopted by other anti-realists, he still finds his position to be more akin to the anti-realists than the realists. As with Putnam he argues that practices of justification are all that can be studied and that the further question of whether they lead to truth, must be abandoned. This, therefore, undermines the attempt to ground epistemological practices or to place philosophy in the role of an adjudicator of genuine knowledge. Instead of placing itself beyond other epistemological traditions philosophy is to mediate instead in a 'conversation' between distinct traditions. Unlike Putnam, who sees his antirealism as a step forward, at least for the analytic philosophers who had abandoned the continental tradition in metaphysics, Rorty sees his anti-

realism as part of an 'end' of philosophy. The metaphysical picture of realism, and with it the epistemological project that accompanies it, and which has defined modern philosophy, must give way to a post-modern abandonment of that traditional project.

Anti-realism thus takes various forms, though generally adopting a semantic thesis concerning the meaning of terms that go beyond experience. There is also an epistemological aspect to anti-realism in the common denial of a great gap between justified belief and truth, of the world as 'found' and as somehow 'constructed' by humans. Many anti-realists, as well, are finding a renewed interest in post-Kantian German philosophy as a way of articulating their views. Anti-realism as a philosophical phenomenon invites speculation about the course of analytic philosophy as beginning with the rejection of idealism by Moore and Russell, and ending with a return to it. Anti-realism is also often associated with the more general cultural phenomenon of 'post-modernism' and is seen not as a return to an earlier idealism but rather as marking the 'end of philosophy'.

CHAPTER 5
Ethics I (1900–45)

Michael Stingl

Early twentieth-century philosophy was largely, in Ian Hacking's neat phrase, the heyday of meanings. This is not to say, as Hacking stresses in his book *Why does Language matter to Philosophy*? [5.22], that the point of the philosophy of this period was to study meaning: the point of studying meaning was to do better philosophy. The general focus of the period was on the words or phrases used in asking or attempting to answer the questions of traditional concern to philosophy, and in particular, how, or even if, these terms were meaningful. Its philosophical conceit was that once meaning was clarified, philosophical truths could easily be distinguished from philosophical confusions. But by the end of the period even this had become unclear; by then, the central question of philosophy was whether there were, in fact, any truths of the kind that philosophers had traditionally supposed themselves to be after. The worry was that once their meaning was clarified, traditional philosophical questions would show themselves to be literally meaningless.

The focus of the moral philosophy of the period was on meta-ethics, and more specifically, the question of whether, once the meaning of terms like 'good' and 'right' had been clarified, a science of ethics might be possible. For while science, and in particular physics, seemed to be logging in one stunning success after another, ethics seemed no closer at the beginning of the twentieth century to anything that might count as moral knowledge than it had been at the time of the early Greeks. Or so things seemed to G.E.Moore, who set out in 1903 to clarify once and for all the meaning of 'good', and in so doing clear the way for a genuine science of ethics, one which might justifiably pretend to give us definitive knowledge of right and wrong.

MOORE'S *PRINCIPIA ETHICA*

My 1971 paperback copy of *Principia Ethica* bears this advertisement:

> What is GOOD?
>
> To answer this question, G.E.Moore wrote one of the most influential books of this century—*Principia Ethica*
>
> [5.44]

Cover advertisements being what they are, it is not surprising to find this one standing distinctly at odds with what might be called the received view of Moore's book among philosophers more contemporary with the particular edition it adorns. A representative example of this view is furnished by Alasdair MacIntyre's *A Short History of Ethics:*

> [Moore] says that if we consider *good* and, let us say, *pleasant,* or any other notion with which we might be tempted to confuse *good,* we can see that we 'have two different notions before our minds'. This technique of holding one's concepts up to the light, as it were, is reinforced by Moore's method of calm assertion. More unwarranted and unwarrantable assertions are perhaps made in *Principia Ethica* than in any other single book of moral philosophy, but they are made with such well-mannered, although slightly browbeating certitude, that it seems almost gross to disagree. But what, then, *is* Moore's case?
>
> ([5.35], 250)

Not much, MacIntyre goes on to suggest. And generally speaking, this is the received view of Moore's book among philosophers in the second half of the century: a Pandora's box filled to overflowing with singularly unpersuasive arguments, many of them directed at wildly mistaken readings of the earlier moral philosophers against whom Moore took himself to be providing definitive criticism.

One of Moore's main targets was John Stuart Mill. Like Moore, Mill was a utilitarian. And like all utilitarians, Mill advanced two linked moral theories, a theory of the good and a theory of the right. The general idea behind the utilitarian combination of these two sorts of theories is that one can't really say what kinds of actions are right until one is able to say what sorts of outcomes are good. Simply put, right actions are those which produce good consequences. What one needs, then, at the very foundation of any moral theory is an account of what kinds of things are intrinsically valuable: things worth pursuing not merely as means to some other thing, but in and of themselves. Some utilitarians, Mill arguably among them, offer a purely subjective theory of the good, one that takes particular states of consciousness, such as pleasure or happiness, as being the only things that are intrinsically valuable, good in and of themselves. Other utilitarians, like Moore, offer a more objective theory of the good: some things are intrinsically valuable, such as knowledge or friendship, whether they happen to make human beings happy or not.

Moore's chief criticism of Mill was not so much that he had proposed a mistaken theory of the good, but that he had made a deeper, meta-ethical mistake, one which had then led him to misidentify the sorts of things that might properly be said to be good.

To understand the point of this criticism, we need to start with the passages in Mill's *Utilitarianism* against which it is targeted. In his first chapter, Mill claims that

> [q]uestions of ultimate ends are not amenable to direct proof. Whatever can be proved to be good must be so by being shown to be a means to something admitted to be good without proof.
>
> ([5.37], 4)

Later, in chapter IV, entitled 'Of What Son of Proof the Principle of Utility is Susceptible', Mill repeats his assertion that questions of ultimate ends, questions, that is, about what things are good in and of themselves, do not admit of strict proof. He goes on to say the following:

> Questions about ends are, in other words, questions [about] what things are desirable. The utilitarian doctrine is that happiness is desirable, as an end; all other things being only desirable as means to that end.
>
> The only proof capable of being given that an object is seen is that people actually see it. The only proof that a sound is audible is that people hear it; and so of the other sources of our experience. In like manner, I apprehend, the sole evidence it is possible to produce that anything is desirable is that people do actually desire it.

([5.37], 34)

That these last two 'passages have become as well known as they have is due, in no small part, to their almost equally well-known rejoinder in *Principia Ethica:*

> There, that is enough. That is my first point. Mill has made as naive and artless a use of the naturalistic fallacy as anybody could desire. 'Good', he tells us, means 'desirable', and you can only find out what is desirable by seeking to find out what actually is desired.
>
> The important step for ethics is…the step which pretends to prove that 'good' means 'desired'…. Well, the fallacy in this step is so obvious, it is quite wonderful how Mill failed to see it.
>
> ([5.44], 66–7)

His discovery of the 'naturalistic fallacy' was for Moore the centrepiece of *Principia Ethica*. On the one hand, it turned out to be ubiquitous, 'to be met with in almost every book on Ethics'. On the other hand, the failure to understand it for what it was blocked all progress in ethics, for to commit the fallacy was to misunderstand the very nature of goodness. If we don't understand what goodness is, we are hardly in any position to say what sorts of things are good, much less what kinds of actions are right. So what then was this alleged fallacy, the discovery of which was so propitious? According to Moore, it was simply the most prevalent form of what we might call, following the subsequent discussion of William Frankena's 'The Naturalistic Fallacy' [5.20], the definist fallacy: the fallacy of supposing that the property of goodness can be defined in terms of some other property or set of properties.

In the naturalistic version of the fallacy, the other property in terms of which goodness is defined is a natural one. In Mill's case, for example, 'good' is said to be defined as 'desired'. Now whether or not a desire exists is a question of human, or perhaps animal, psychology; in any case, it is a question that can be answered by empirical investigation. It is a question, that is, about some state of the natural world, in this case the actual psychological state of some creature or another. On this view, then, to see what's good in and of itself, we simply check to see what, in point of actual fact, people desire in and of itself. And here Mill's answer would seem to be short and to the point: happiness.

Against Mill, Moore thought that any move to define goodness in terms of some other property, natural or not, could be conclusively shown to be fallacious by an appeal to what has come to be called the open question argument. An open question is one whose answer is not immediately obvious, but instead requires further thought or investigation. Moore's point is that for any proposed definition of goodness, we can raise an open question of the form 'but is this good?' Regarding Mill's view, for example, we can raise the question, 'but is happiness good?' That this question is an open one proves that goodness can't be defined as happiness, for then we should only be asking 'but is happiness happiness', a question which certainly isn't open. Because it can be applied to any proposed definition of goodness, the open question argument appears to be a powerful one: if it works, it shows that goodness is undefinable.

This, in fact, was Moore's conclusion: the property of goodness is a simple, undefinable, non-natural object of thought. Like *'yellow',* there may be some other property that all good things possess; but 'good', like *'yellow',* denotes something else, a property that we know by direct acquaintance. With regard to yellow, we know it when we see it. Now it may of course be that all things that are yellow turn out to reflect light in a particular sort of way, but to be able to meaningfully claim that this is so, we cannot mean the same thing by 'yellow' and 'reflects light in such and such a way'. Rather, we know what yellow is by direct perceptual acquaintance with yellow things, and we go on to find out what physical property all yellow things possess by studying the reflective properties of light. Similarly, we know what goodness is by some

sort of direct cognitive acquaintance with it when we contemplate good things, and it is then up to the science of ethics to tell us whether there is some other property, or set of properties, that can be linked to goodness.

It is in this sense that Moore can be called an intuitionist, although he himself rejected the label. There is a property of goodness of which we can be directly cognitively aware, but since this awareness is obviously not perceptual, it must be of some other, purely intellectual kind, perhaps something like our awareness of mathematical objects. In any event, since we are not aware of goodness perceptually, and it is not definable in terms of other perceptual properties, it follows that it must be a non-natural property.

This raises three important philosophical problems. First, there is the metaphysical question of just what sort of property this 'nonnatural' property might be. Second, there is the related epistemological question of how knowledge of it would actually be possible. Lastly and perhaps most importantly for ethics, there is the question of how goodness so understood might be connected to the human motivational system. How could knowledge of a non-natural property of the world be motivationally effective? How could it, that is, give us a reason, much less an obligation, to act?

These were not problems that Moore concerned himself with in *Principia Ethica;* the point of the book was simply to clarify the meaning of 'good', and then to begin pursuing what Moore took to be the chief task of the science of ethics, attempting to identify the class of things that actually did possess the simple, non-natural property of goodness. The good, as something distinct from goodness, was thus something that Moore thought it might be possible to define, and indeed, this is precisely what he thought ethics should try to do: define precisely that class of things that were, in fact, good. His fundamental point was that the question about the good was parasitic on the logically prior question about the definition of goodness; ethics couldn't begin to address the former without an answer to the latter. This, in short, was Mill's mistake. Having confused the two questions, he had turned a plausible but incorrect answer to the question of what sorts of things might be good into an utterly fallacious answer to the question of what goodness itself might be.

As indicated earlier, history has not been kind to Moore. Ironically, later philosophers have been as abrupt with him as he was with Mill. In 'The "Proof" of Utility in Bentham and Mill', Even Hall argues that Mill is guilty of no fallacy. He begins his vindication of Mill with this critical barb:

> I can only account for this flagrant reading into Mill of the definist fallacy by supposing that Moore could not grasp any other sense to Mill's argument and so thought that Mill *must* have committed this fallacy. But *there is* another and obvious sense to any interpreter not debauched with verbal casuistry.
>
> ([5.23], 150)

This other, obvious interpretation calls attention to the fact that Mill begins the passage that is the focus of Moore's attack with the caveat that no proof of his theory of the good is possible. His point is that even if strict proof is impossible, there may still be other, less rigorous tests to which proposed theories of the good might be held accountable. According to Hall, then, what Mill is doing in the passage in question is suggesting just such a test: whatever a theory says is good had better be the sort of thing that actually motivates people to act. So in arguing that people actually desire happiness, Mill is not offering a definition of goodness, but attempting to show that his proposed theory of the good passes an important empirical test, a test of motivational efficacy. According to the doctrine of psychological hedonism, people are ultimately motivated, in fact, by what they think will make them happy. Hall's point is that, although this psychological doctrine is deeply problematic, Mill's appeal to it in the context of trying to justify his theory of the good commits no logical mistake.

Moore undoubtedly got Mill wrong. Yet *Principia Ethica* was influential, and its influence was not inconsiderable. To see why, we must place the book and its arguments in their original context. We must ask why Moore would have been so absolutely convinced that whatever Mill himself might have thought that he was doing, part of what he was doing, if he was doing anything at all, was offering a definition of goodness. In particular, we must ask why Moore would have found the open-question argument such a thoroughly damning criticism against any attempt to define goodness.

Moore's is a case where language very clearly mattered to philosophy. Unless his concern with ethics as a science is placed in the context of the referential theory of meaning which he and Bertrand Russell were beginning to develop in the early decades of the century, the main moral arguments of *Principia Ethica* can only appear as they have to many of Moore's critics: as pompous as they are misguided.

On the referential theory of meaning, powerfully developed by Russell in 'On Denoting', *The Principles of Mathematics, Principia Mathematica* and *The Problems of Philosophy,* and less powerfully developed by Moore himself in the opening pages of *Principia Ethica,* the meaning of a term was just what it referred to. According to the earliest versions of this theory, some terms, like 'Socrates', referred to particular individuals; others, like 'yellow', to universals, in this case the property universally shared by all yellow things. To know what a sentence meant, one needed to know the meanings, or referents, of its terms. So to say what sorts of things were good, at least in a philosophically informative sort of way, Mill would have had to have been clear about what it was that 'good' referred to. And on this point, it would seem, Mill does not disappoint: he seems to say quite clearly that 'good' is what people desire, and what people desire is happiness. But in the context of Moore's referential theory of meaning, this is just as clearly absurd; as the open question argument conclusively shows, whatever 'good' refers to, it cannot refer to happiness. Thus the point of the Bishop Butler quote which prefaces *Principia Ethica:* everything is what it is, and not another thing. Whatever goodness is, it is not happiness.

Now someone who held the referential theory of meaning to be true might try to defend Mill by saying that what he was trying to do in the contested passage was to argue, in an admittedly misguided way, that 'good' and 'desired', like 'yellow' and 'reflects light in such-and-such a way', are extensionally equivalent: all and only all those objects are good which are also desired. Mill didn't, then, suppose that 'good' referred to what people desire, happiness, but he did think that the properties of intrinsic goodness and happiness were shared by exactly the same class of objects. Moore's second line of defence, however, would once again be tied to his own understanding of the referential theory of meaning: if Mill had had any understanding at all that 'good' referred to goodness itself and nothing else, he would not have gone on to propose the obviously mistaken doctrine that happiness was the sole good. Moore thought it obvious, that is, that once anyone grasped the idea of goodness as an independent object of thought, he or she would see that goodness attached itself to things like friendship and knowledge, as well as happiness. To reach the conclusion that he did, Mill must have been, to some significant degree, confusing goodness with happiness.

But if locating *Principia Ethica* within the context of a particular theory of language and meaning displays the true mettle of its arguments, it also makes clear their ultimate infirmity: they are only as good as the theory of meaning they presuppose. And while the referential theory of meaning was only to reach its final flourish in the 1921 publication of Ludwig Wittgenstein's *Tractatus,* the quickness of its subsequent demise was surpassed only by the finality of its eventual rejection. Still, not unlike certain of the doctrines of the *Tractatus* which continue to fascinate the philosophical mind long after it has categorically rejected them, the arguments of *Principia Ethica* have continued to haunt philosophical thinking about ethics. Moore showed that language could not be ignored when doing ethics, and that unless moral philosophers could give some indication of what words like 'right' and 'good' meant, no progress in the purely philosophical

pursuit of ethics was possible. Moreover, the philosophical problems posed by Moore's objective theory of the good have become important puzzles to be solved by any successful approach to ethics: whatever moral value turns out to be, how is knowledge of it possible, and how does it function to motivate human beings to act? Attempts to answer these questions are at the heart of the naturalism of Perry and Dewey, the emotivism of Ayer and Stevenson, and the contractarian moral and political philosophy of the current day.

INTUITIONISM

They are also at the heart of intuitionism, although its answer to them is ultimately no more cogent than Moore's.

The impetus for intuitionism was H.A.Pritchard's 1912 *Mind* article, 'Does Moral Philosophy Rest on a Mistake?' [5.49]. The question, as one might suppose, was rhetorical. According to Pritchard, the problem with all earlier moral philosophy was that it failed to give a convincing account of moral obligation: it failed to give a satisfying answer to the question of why one *ought* to do the right thing. The mistake behind all such failures was to suppose that this question could be answered by some sort of proof. Once one saw that it could not, one was free to see that no proof is in fact necessary: that one ought to do the right thing is part of one's direct apprehension of the act in question as being right.

One might, like Moore, attempt to ground the obligatoriness of right acts in the fact that they lead to good outcomes. But this, as Pritchard says, 'presuppose[s]…that what is good ought to be', which is false. Certain states of the world, such as an end to human suffering, may indeed be very good things; but the fact that an end to human suffering is good does not entail, by itself, that I or anyone else possesses an obligation to bring it about. Nor does the alternative of supposing that right acts are themselves good fare any better, for good acts, according to Pritchard, are simply right acts done for the right reasons. That an act is a good one, that is, has completely to do with its motive, which for Pritchard has nothing to do with its rightness; doing *what* we ought to do, says Pritchard, is completely divorced from doing it *as* we ought. The underlying idea here is that if rightness cannot be derived from goodness, then neither can moral obligation.

Towards the end of his paper Pritchard briefly develops a more general argument that our obligation to do the right thing admits of no philosophical proof. To prove that we know anything, Descartes thought that we had to prove that we know that we know it. But this, says Pritchard, is impossible: it leads epistemology into an infinite regress. The parallel with ethics is this. Just as in the face of past mistaken beliefs we are led to wonder how we know what we think we know, in the face of conflicting inclinations we are led to wonder why we ought to do what we think is right. But if we suppose that to answer the question of why we ought to do what we think is right we must find some sort of proof that we are so obliged, we make the task of ethics impossible. In looking for such a proof, we would be looking for something that would oblige us to be obliged to act in a certain way; something, in other words, which would threaten the same sort of regress that makes the Cartesian epistemological project an impossible one. If I can only be obliged to do the right thing by being obliged to be so obliged, it is not clear why this same problem about obligation doesn't simply reassert itself one level down.

Pritchard's rejection of the task of traditional epistemology is an interesting precursor to the current rejection of the philosophical search for necessary and sufficient conditions for '*s* knows that *p*' in favour of the empirical study of the cognitive processes that actually produce what we would otherwise be willing to think of as knowledge. But strangely enough, despite his insight that the question of why we ought to do what we ought expresses a similarly misconceived demand for absolute certainty, Pritchard's own account of moral obligation is quixotically Cartesian: we know it when we see it. If someone doesn't feel obliged to

perform a right act, he or she has merely failed to concentrate fully enough on what it is that makes the act right. To apprehend the act as right is to apprehend it as obligatory.

This, then, is the leading idea of intuitionism: the question of what it is right to do is wholly independent of any arguments regarding what is good, and indeed, what it is right to do is not something for which *any* argument can be given, whether it appeals to the good or not. That an act is right is something that must be directly apprehended.

This idea of direct apprehension is to some extent further developed by W.D.Ross in *The Right and The Good* [5.52] and *Foundations of Ethics* [5.53], and by E.F.Carritt in *The Theory of Morals* [5.7]. According to Ross, what we apprehend in apprehending rightness is something about *types* of acts. It is because we see, for example, that an act is the keeping of a promise, that we are able to intuit that it is right. The recognition that certain types of acts, such as keeping promises, telling the truth, and repaying one's benefactors, are right is for Ross the basis of his theory of *prima facie* duties: types of acts that are *prima facie* right. Duties so understood are *prima facie* right rather than actually right, since in certain situations they may come into conflict with one another; in such situations, only one *prima facie* duty can be one's actual duty. As we shall see below when we examine this theory in more detail under the heading of 'Substantive Ethics', what our actual duty is is not something that we can directly intuit.

This point is explicitly denied by Carritt, who is in many ways a precursor of what is today called situational ethics. On Carritt's view moral intuition applies itself directly to particular situations, in their full particularity. What we intuit is that *this* act, in *this* situation, is right. We may later realize that our intuitions fall into certain general types, perhaps according to Ross's list of *prima facie* duties; but these types are not a part of what we directly intuit. In a deep sense, no theory of ethics is possible. Thus Carritt:

> You cannot prove to a man that he has duties, or should do his duty, or that justice is a duty, or that this act is just. All you can do is give him fuller information of the consequences and antecedents of what he is doing and then ask him to agree with you that it is right or wrong. If he knows the situation and consequences as well as you do and still differs, one of you must be wrong. All you can do is get him to imagine the situation again and repeat the act of moral thinking with greater attention.
>
> ([5.7], 72)

A modest view of ethics, perhaps, but in the end one which is no less extravagant than Moore's account of goodness. To say that we know 'by intuition' what things are right does nothing to tell us how we are epistemologically connected to the moral value at issue, much less what that connection might have to do with the actual structure of the human motivational system. It is a curious feature of the human intellect that explaining something mysterious by appealing to something even more mysterious has the attraction that it does. Still, the deeper mystery can remain intellectually satisfying only as long as there are no other explanations on the field which possess what it does not, some real explanatory power. This is why it has proved historically necessary, where the deeper mystery has been emotionally and politically satisfying, to have at one's disposal the stake, along with the various other unpleasant instruments of non-rational persuasion: instruments unavailable to the intuitionists, as the despairing quote from Carritt makes only too clear. If some poor soul cannot see that what is plainly right is plainly right, we must attempt to open his or her eyes, over and over again, until one of us tires and gives in or up.

NATURALISM

By defining moral values primarily in terms of human interests, the naturalists were able to offer what the intuitionists were not: a straightforward answer to the question of how moral knowledge was possible, as well as to the deeper question of how such knowledge could be motivationally effective.

For both Moore and the other British intuitionists, morality was objective in the sense that moral values, like goodness, were to be found among the qualities of objects as these existed independently of any and all subjective experience. For the naturalists, this idea of moral objectivity was absurd. In *The Winds of Doctrine,* the American philosopher George Santayana offered the following argument:

> For the human system whisky is truly more intoxicating than coffee, and the contrary opinion would be an error; but what a strange way of vindicating this real, though relative, distinction, to insist that whisky is more intoxicating in itself, without reference to any animal; that it is pervaded, as it were, by an inherent intoxication, and stands dead drunk in its bottle!
>
> ([5.60], 267)

According to Santayana, that whisky is intoxicating is a relational fact about the world, a fact, that is, which involves not only the chemical properties of alcohol, but the physiological properties of the human constitution. So too for moral facts: that something is morally good is a relational fact involving creatures with certain interests and capacities for purposeful action, and an environment in which it is possible for them to act so that more rather than fewer of their interests are satisfied.

The idea of an ethics thus naturalized was further developed by two other American philosophers, Ralph Barton Perry and John Dewey, both of whom tried to give more exact definitions of what moral goodness might amount to on such an approach.

In his *General Theory of Value* [5.47] and its sequel, *Realms of Value* [5.48], Perry suggested that we should say that something possessed value if and only if it was the object of an interest, and that it was morally good if and only if it was the object of an interest which was itself a member of a set of interests harmoniously arranged. By the term ‘interest’ Perry meant to include any attitude of a subject towards an object which was favourable or disfavourable; his examples of such attitudes are liking and disliking, hoping and fearing, and desiring and avoiding. In so far as animals could feel dislike or aversion, they too had interests, and although they themselves could not be active participants in the harmonious arranging of interests, their negative interests, at least, had to be taken into account under any such arrangement. On the naturalistic view developed by Perry, this was because unsatisfied interests were, objectively speaking, bad.

By ‘interests harmoniously arranged’, Perry seemed to have in mind something similar to an idea developed more recently by John Rawls in his *A Theory of Justice* [5.50], the ideal of a well-ordered society. And while this idea is also to be found in John Dewey’s *Theory of the Moral Life* [5.15], neither he nor Perry ever developed it fully. At its most general, the idea is this: interests cruelly conflict; some interests are more significant than others; human beings flourish only in social environments; the best set of interests, both within and across lives, is therefore a set of interests which are mutually reinforcing. Our lives are best structured, then, when the satisfaction of my interests is part of the satisfaction of yours, and vice versa. It is in this sense, in a well-ordered society, that the interests of each become the interests of all.

All this, of course, claims to be doing exactly what Moore said could not be done: providing a definition of moral goodness. In partial agreement with Moore, Perry did think it impossible to replace the concept of goodness, or more generally, value, with some alternative set of concepts which would mean the same thing, but express that meaning in a more readily comprehensible fashion. Perry did, however, think it entirely po sible to replace our actual concept of value, the contours of which were at best vague and at worst

ambiguous and confusing, with a more precise alternative, the merit of which was to be assessed in terms of how well it enabled us to carry out our reflections about value, moral or otherwise. Given the nature of this sort of reforming definition, the significance of the open question argument for Perry was simply to voice the demand that for any reform proposed, acceptance should be conditional on its proving to be more interesting and fruitful than its rivals; then and only then could that sort of thing, whatever it turned out to be, be said to be good by 'definition'.

Like Santayana, Perry was not a moral objectivist in the sense intended by Moore. He was greatly concerned, however, to establish a distinction between having an interest in something and making a judgement about that interest, so that a thing's value would not, in the end, consist in the mere fact that it was judged to possess value. That things are valuable only because they are judged to be so is the characteristic mark of moral subjectivism, a view vigorously disavowed by the naturalists.

Dewey's effort to avoid subjectivism was in some respects more subtle than Perry's, in others less. Instead of trying to finesse his way around the great metaphysical divide of subject and object assumed by Moore's notion of moral objectivity by arguing for some sort of secondary epistemological divide, such as that between interest and judgement, Dewey argued that the widely shared metaphysical assumption was itself a mistake. The upshot of his argument is compactly stated in chapter VIII of *The Quest for Certainty:*

> If we see that knowing is not the act of an outside spectator but of a participator inside the natural and social scene, then the true object of knowledge resides in the consequences of directed action.
>
> ([5.14], 196)

If an experimental interaction between us and the world yields the result we expected, to that extent we have gained objective knowledge of the world. The experiment may be one of physics or it may be one of morality: in either case the general method is the same, and what it tells or fails to tell us is no more objective in the one instance than the other.

In short, moral knowledge is generated, according to Dewey, through the general scientific method of hypothesis and experiment. In contrast to Moore's idea of what a science of ethics might look like, this sharing of a single methodology was, for Dewey, the only way in which ethics might be genuinely scientific. To take an example from the first edition of Dewey's and James Tuft's *Ethics* (1908), the moral ideal of individualism that served to legitimate the excesses of the robber-barons of early twentieth-century North America was a hypothesis that was in the process of being shown to be dramatically mistaken. The moral expectation in which the hypothesis was grounded was that a social order so inspired and arranged would be more stable and productive than one based, say, on principles of a more socialist bent. The social upheaval of the times made it clear, according to Dewey and Tufts, that this was not so. The failed experiment of unrestrained capitalism showed that a purely individualistic moral ideal was incapable of producing a set of social interests harmoniously arranged.

In addition to offering a coherent account of moral knowledge, Dewey's naturalism offered a coherent account of moral motivation. If the experimental method promised to show us how our interests might be best arranged into complex social wholes, education promised to produce individuals with the right sorts of interests. That we should restructure the basic institutions of our society to produce such individuals was first to be grasped by intelligence, and second, to be pursued out of self-interest and sympathy. Once our intelligence showed us that our own particular good was essentially tied to the good of those around us, self-interest and sympathy would push us to pursue the greater good of interests harmoniously arranged. The most direct way of doing this, of course, was to start with individuals whose interests were not yet formed, and educate them in such a way that the interests they did form were of the appropriate sort.

Whatever other worries it might raise, this quick sketch of Dewey's account of the human motivational system leads us to the deepest meta-ethical objection that later philosophers have had to ethical naturalism, the objection that while human motivation is one thing, moral obligation would seem to be quite another. Put another way, how does what naturally *is* get us to conclusions about what morally *ought to be*? This worry, sometimes called the is/ought dilemma, has been taken by at least some later philosophers to be the real point of the open question argument, whether Moore realized it or not. On this view, the naturalistic fallacy is the unadorned move from the claim that something is naturally good for us, perhaps because of the kind of creatures we are, to the further claim that this natural fact gives us an obligation to pursue that thing. Interests harmoniously arranged might, as a point of natural fact, be good for us; but how does this create an obligation, on anyone's part, to pursue such an arrangement?

In his *Theory of the Moral Life* [5.15] and *Human Nature and Conduct* [5.13], Dewey offers a response to such worries. At its briefest, his argument is that the moral obligation to arrange our interests harmoniously is derived from the human necessity of a social existence:

> social pressure is involved in our…lives, as much so as the air we breathe and the ground we walk on. If we had desires, judgements, plans, in short a mind, apart from social connections, then the latter would be external and their action might be regarded as a nonmoral force. But we live mentally and physically only *in* and *because* of our environment. Social pressure is but a name for the interactions that are always going on and in which we participate, living so far as we partake and dying so far as we do not.
>
> ([5.13], 327)

Beyond the bare desire to lead a human life, there is for Dewey no deeper answer possible to the question of why we ought to do what it is good for us to do.

LOGICAL POSITIVISM

Whatever their philosophical merits or shortcomings might have been, ethical naturalism and moral intuitionism were both swept away by the rising tide of logical positivism.

Logical positivism was a general approach to problems of language and meaning. As a movement, its genesis and early growth was within the Vienna Circle, a group of scientists and philosophers who met, in Vienna, from the early 1920s to the mid-1930s. Two of the more important figures in the Circle were Moritz Schlick and Rudolf Carnap, and although Ludwig Wittgenstein was never actually part of it, his *Tractatus Logico-Philosophicus* and some of his subsequent ideas greatly influenced the Circle's discussions and views. Among English-speaking philosophers, A.J.Ayer was briefly associated with the Circle; in 1936, he published its chief polemical text, *Language, Truth, and Logic*. At the centre of this book was the principle of verification:

> We say that a sentence is factually significant to any given person, if, and only if, he knows how to verify the proposition it purports to express—that is, if he knows what observations would lead him, under certain conditions, to accept the proposition as being true, or reject it as being false.
>
> ([5.2], 35)

According to the positivists, sentences expressing scientific propositions obeyed this principle. Because they could be observationally tested, they were meaningful. According to all the positivists except Schlick, the

sentences of ethics did not; because moral claims could not be observationally tested, they were literally meaningless. On this view of science and ethics, then, no science of ethics was possible.

Three qualifications are important here. First, there is the problem of naturalism; if Dewey, for example, was right in his claim that moral judgements were best understood as hypotheses about how interests might be best arranged, then it would seem that moral claims could be tested by observation. Against this, Ayer sided with Pritchard's point that claims about the good could not tell us anything about moral obligation. This point has been echoed by a number of philosophers in the positivist tradition, starting with Wittgenstein's remark (6.41) in the *Tractatus* that if values were part of the world, they would be in an important sense 'accidental'. The general idea was that although goodness naturally defined might tell us important psychological or social truths about human beings, truths that were contingent on the way the world turned out to be structured, it could not tell us any truths about what ought to be. In Ayer's terminology, naturalistic accounts of moral language missed the point of the normative use of terms like 'good' and 'right', which was to goad us into action.

This point leads us to a second qualification: to say that moral claims were literally meaningless was not to say that they had no meaning at all. Some claims, like those of science, were only meaningful in so far as they described, truly or falsely, the world disclosed to us by observation. Other claims, however, might be meaningful because of the ways in which they allowed us to express our feelings. Such a view of moral claims, embraced by all the positivists except Schlick, who was an ethical naturalist, came to be known as emotivism. In the English-speaking world, an emotivist account of the meaning of moral terms was first articulated in 1923 by C.K.Ogden and I.A.Richards in *The Meaning of Meaning:*

> 'good' is alleged to stand for a unique, unanalysable concept. This concept, it is said, is the subject-matter of Ethics. This peculiar ethical use of 'good' is, we suggest, a purely emotive use. When so used, the word stands for nothing whatever…it serves only as an emotive sign expressing our attitude… and perhaps evoking similar attitudes in other persons, or inciting them to actions of one kind or another.
>
> ([5.46], 125)

In discussing this view in 'Is "Goodness" the Name of a Simple, Non-natural Quality?' [5.5], C.D.Broad aptly characterized it as the 'Hurrah-Boo' theory of moral language. For according to emotivism, when I say, for example, that stealing is wrong, all that I really mean is, 'Boo on stealing!' This makes it hard, of course, to see how such a theory might ever begin to make sense of moral argumentation, a worry raised by G.E.Moore in 'The Nature of Moral Philosophy'. If I say 'Boo' to something to which you say 'Hurrah', there is no claim to the truth of which we disagree about; I merely express my feelings about the thing, and you yours.

Ayer's response to this worry was to meet it head on, and to deny that moral disputes were, in fact, possible. Ayer claimed that in a 'moral' disagreement with someone we might argue over facts relevant to the case, or even over questions of whether those facts fell within the purview of this moral principle or that; what we could not argue over was why someone should accept one moral principle as opposed to another. That we are able to get along as well as we are, as often as we are, was for Ayer a simple artifact of our having been brought up within particular societies, defined by certain shared values.

But this view of moral disputes hardly begins to do justice to the ways in which we actually argue about ethical issues. In a series of important articles, culminating in 1944 with his *Ethics and Language,* Charles Stevenson tried to extend the emotivist account of moral argumentation. He agreed with Ayer that at least

some putatively moral disputes were really nothing more than disputes regarding the facts of the matter at issue. For Stevenson, however, there could be genuine moral disagreements:

> We must distinguish between 'disagreement in belief (typical of the sciences) and 'disagreement in interest.' … Disagreement in interest occurs when A has a favourable interest in X, when B has an unfavourable one in it, and when neither is content to let the other's interest remain unchanged.
>
> ([5.66], 426)

In the course of such disagreements, each of A and B will attempt to influence the other to drop or otherwise modify his or her original interest in X. The most important way of doing this is to use what Stevenson calls the persuasive method, which

> depends on the sheer, direct emotional impact of words—on emotive meaning, cadence, apt metaphor, stentorian, stimulating, or pleading tones of voice, dramatic gestures, care in establishing *rapport* with the hearer or audience, and so on.
>
> ([5.69], 139)

Something of an advance, to be sure, over the method of moral persuasion advocated by Carritt.

Yet whatever its inadequacies as a descriptive theory of moral argumentation, emotivism does offer a coherent story about moral motivation. Unlike naturalism, however, emotivism regards the problem of moral knowledge as moot, a point which leads us to the third important qualification of its claim that moral judgements are literally meaningless.

Emotive meaning is not descriptive meaning. Moral judgements, that is, are in the end no more about the subjective realm of human feelings and interests than they are about the objective realm of natural or non-natural goodness. While moral judgements express feelings, they do not, except perhaps incidentally, serve to describe those feelings. Emotivists, like the naturalists, emphatically disavowed subjectivism, but only because they believed that moral judgements, in their purely normative use, had no prepositional content. Another way of putting this point is to say that moral claims do not express cognitive judgements about the way the world is, subjectively, objectively or even relationally. For this reason, emotivism and its descendants are often referred to as non-cognitivist theories of ethics.

Narrowly construed, logical positivism gradually sank under the weight of its own assumptions. As might be remarked from Ayer's preface to the second edition of *Language, Truth, and Logic,* it turned out to be extremely difficult to state the verification principle in a coherent fashion. As a distinct school of thought, logical positivism has since given way to more generally empiricist approaches to language, meaning and knowledge. Regarding ethics, however, the situation is more confused; by 1945, emotivism had swamped its chief rivals, intuitionism and naturalism. But since then emotivism has itself been swamped by a widely disparate variety of alternatives, some of them non-cognitive, some of them not, each about as plausible as the next. Still, as the twentieth century draws to a close, it would not be unfair to say that the influence of positivism in general, and emotivism in particular, has been much more pervasive than that of either intuitionism or naturalism.

More lasting as enigma than influence has been the ethical doctrine of Wittgenstein's *Tractatus*. The central logical claim of the book, that the limits of what can be meaningfully said extend no further than empirical propositions about the world of the natural sciences, was eagerly embraced by the early positivists. For Wittgenstein, however, this logical point was itself of the utmost moral importance. In showing the limits of what could be said, Wittgenstein took himself to be showing the limits of the world, in

its entirety. What he took to be of deep moral importance was that in showing the limits of the world, he showed that he himself could not be part of it. As a psychologically or physically describable subject of desires, experiences or actions he certainly was a part of the empirical world; but as the metaphysical subject who saw what logic showed about its limits he certainly was not.

Since the metaphysical subject was not part of the world, nothing that happened in the world could affect it for good or ill; goodness or badness must lie wholly within the metaphysical subject itself, quite apart from the actual events of the empirical world. What this meant for Wittgenstein was that the good person, the happy self, was the self who completely identified with the world as a whole: the self who accepted whatever happened without trying to alter the course of events to satisfy the desires of the particular empirical subject with whom it might otherwise and unhappily be tempted to identify itself. Wittgenstein's own ethics, with its roots in the decidedly un-English intellectual tradition of Vienna and the late Habsburg empire, was thus entirely out of step with the approaches to moral philosophy being developed in either England or the United States in the first half of the twentieth century. It is unlikely that either Russell or Moore, for example, Wittgenstein's examiners when he submitted the *Tractatus* for a degree at Cambridge and two of the English philosophers who knew him best, ever really understood the main unstated claim of the book which according to Wittgenstein was more important for what it didn't say than what it did: the stark moral command found in his *Notebooks 1914–1916* to 'Live happily!'

SUBSTANTIVE ETHICS

As remarked at the outset, the main focus of the moral philosophy of the first half of the century was on meta-ethical questions pertaining to the meaning of moral terms. Questions of substantive ethics—questions, that is, about what sorts of things might actually be good or bad, right or wrong—took what seemed to be a legitimate second place to questions about what one might mean in applying these terms to one thing or another. Nevertheless, in so far as at least several of its participants thought themselves to have successfully settled such questions of meaning, the period also included two significant developments with respect to questions of ethics proper.

The first development, already mentioned, was Ross's theory of *prima facie* duties. This theory is deontological, since it takes questions of rightness, or duty, as the basic questions of ethics, rather than questions about goodness. For Ross, the foundations of morality were to be found in our intuitions about right and wrong, intuitions which disclosed to us moral truths about certain types of actions: telling the truth, lying, keeping or violating promises, respecting or failing to respect human life or property. While our intuitions told us that keeping promises, for example, was *prima facie* right, they also told us that violating promises was *prima facie* wrong. But what of rightness and wrongness themselves? To take first the simple case, actions which instantiated but one of these types were, in fact, right or wrong, depending on the type of action of which they were an instance. For actions which were instances of more than one type, however, the possibility existed that while on the one hand they might be *prima facie* right, on the other they might be *prima facie* wrong; how were we to know, in such cases, whether the action was right or wrong? According to Ross, this was not something that could be determined by intuition. If, for example, we were confronted with an action that was at once both the keeping of a promise and a lie, the best we could do would be to try and assess the relative weight of the two conflicting *prima facie* considerations in this particular situation, and then choose accordingly.

This has generally been held to be the chief failure of the theory of *prima facie* duties: it is simply not a theory of right and wrong. The point of this criticism is that we typically look to moral theory because we are baffled by the question of what it would be right to do in a particular case. We suppose that if we were

able to determine, in general, what it is that makes right acts right, then we would also be able to see what we ought to do in the particular case at hand. In failing to tell us what rightness might amount to in cases that are morally puzzling, Ross's theory fails to deliver what a moral theory must, if it is to be interesting or useful.

Two other problems with this theory are well put by Dewey in his *Theory of the Moral Life*. His first point is that our moral intuitions are only as good as their source in the actual process of our moral education:

> If the conditions of their origin were intelligent, that is, if parents and friends who took part in their creation, were morally wise, they are likely to be intelligent. But arbitrary and irrelevant circumstances often enter in, and leave their impress…
>
> ([5.15], 125–6)

A second, deeper problem has to do with moral change. To base one's moral theory on intuitions is to make it inherently conservative:

> Men become attached to their judgements as they cling to other possessions which familiarity has made dear. Especially in times like the present, when industrial, political, and scientific transformations are rapidly in process, a revision of old appraisals is especially needed.
>
> ([5.15], 127)

Dewey's 'present' is, of course, in certain respects no longer ours; but his point is not without its current relevance. In our own time of rapid change, John Rawls, for example, bases his theory of justice on what he calls our considered moral judgements in reflective equilibrium. But as feminists and others have pointed out, our considered moral judgements, even in reflective equilibrium, may be deeply divided by differences of race, gender and class. One way of understanding this fairly widespread complaint against *A Theory of Justice* is to see it as a direct response to the conservativism inherent in Rawls' method of reflective equilibrium.

This raises a significant question for the period under study. Where, for example, are the women? They are not, by and large, at the universities, professionally developing theories of ethics. But they are at the centre of a number of important early twentieth-century social movements, directed towards such things as temperance, suffrage, birth control, pacifism and general social reform. In their participation in these various movements, prominent women thinkers wrote books, articles, speeches and letters, all of which must stand as a rich, untapped resource of ideas about right and wrong, good and bad. To reconstruct ethical theories out of these ideas would be a large and challenging task; we can only begin to wonder about its ramifications for a more thorough understanding of early twentieth-century ethics. Would an extra section or two need to be added to a history of the period such as this, to take into account the moral thinking of women and other marginalized groups, or would the whole thing need to be recast? If recent work in feminist ethics provides any measure of the depth of such omissions in the moral philosophy of the latter half of the century, the second, more radical alternative is not at all implausible (Kittay and Meyers [5.34]; Hanen and Nielsen [5.24]).

Given the current unsettled state of philosophical thinking regarding such issues, these questions must remain speculative. This is not to say that they can be fruitfully ignored. For a reliable line on substantive ethics, the considered moral judgements of those in the margins of society are, *prima facie,* a much more important starting point for theory than the considered judgements of those who represent, by and large, the interests of those who wield social power. This is not to say that those in the margins are entirely innocent

of prejudice, but only that social evils are more readily apparent to those suffering them than those profiting from them.

With this thought in mind, let us turn to the second significant theoretical development of the period as it is currently understood, Moore's ideal utilitarianism. Moore believed that once we knew what goodness was —a simple and unanalysable non-natural property—we could then go on to address the question of what sorts of things actually possessed this property. In addition to pleasure, Moore thought it immediately apparent that personal affection and the contemplation of beauty were in and of themselves, quite apart from any pleasure that might be connected to them, good. A little more thought, Moore thought, would suffice to show that knowledge, too, was objectively good. Against Mill's hedonistic utilitarianism, which declared there to be only one intrinsic good, that of pleasure, Moore's ideal utilitarianism thus seemed to provide a broader, pluralistic alternative. The assumption here is that Mill really did believe that pleasure was the sole intrinsic good, a point over which there is currently some debate (Anderson [5.1]); however this debate resolves itself, it is clear that Mill's theory of the good was much more subtle than Moore supposed it to be.

Theories of the good to one side, the basic utilitarian theory of the right is straightforward. If something is good, more of it must be better. Right actions, then, are actions which maximize the good. Depending on the comparative goodness or badness of their consequences, some actions are right, others are wrong, and still others are morally indifferent. Because on such views the rightness of actions depends on the goodness of their consequences, this class of moral theories is often referred to as consequentialist.

Now one might suppose that a consequentialist theory, as opposed to a deontological one, would be a more likely tool of social reform than conservativism. Not so for Moore. Because of the great difficulty attendant upon assessing the overall goodness of any proposal for social change, Moore thought it unlikely that any such change could be shown to be a good thing. His advice, then, was simply to follow certain of what he referred to as the rules of common sense: respect human life and property, keep your promises, and be industrious and temperate. This does not mean, as is often supposed, that in Moore's view we are simply to give ourselves over to all of the many demands of conventional morality; as Tom Regan makes persistently clear in *Bloomsbury's Prophet* [5.51], Moore's point is exactly the opposite. The *only* rules of common sense to which we ought to be obedient are those which have shown themselves beyond all reasonable doubt to provide the social and personal stability required for the free, individual pursuit of good things. This pursuit, rather than the dictates of conventional morality, ought to define our personal lives.

But whatever relevance Moore's views on this point might have had to the liberal principles of tolerance and individual freedom, and however liberating they might have seemed to the upper-class membership of the Bloomsbury Group, the fact remains that he was simply not the sort of social reformer that Mill was. The author of *Principia Ethica* may have been able to endorse the general principles of *On Liberty,* but he would certainly not have been able to endorse the sweeping calls for social change contained in *The Subjection of Women*. Regarding Moore's appeal to common sense, then, the most apposite response from a contemporary moral philosopher is once again Dewey's, from *The Quest for Certainty:*

> It is not for a moment suggested that we can get away from customs and established institutions. A mere break would doubtless result simply in chaos. But there is no danger of such a break. Mankind is too inertly conservative both by constitution and by education to give the idea of this danger actuality. What there is genuine danger of is that the force of new conditions will produce disruption externally and mechanically: this is an ever present danger. The prospect is increased, not mitigated, by that conservativism that insists upon the adequacy of old standards to meet new conditions.
>
> ([5.14], 272–3)

For Dewey, the search for moral knowledge is not something we can so easily choose to abandon. Moreover, the pursuit of such knowledge requires, *contra* Moore, our active moral participation in the world of social and technological change. Because of their probable consequences, participation is morally better than passivity.

Writing in 1929, Dewey could not have foreseen the shattering and abrupt technological disruption of human moral thinking that was to take place in the New Mexican desert on 16 July 1945, at 5:30 in the morning. Among those most directly responsible for the nearly instantaneous release of nuclear energy that took place that day, some physicists, like Niels Bohr and Leo Szilard, vainly attempted to influence the government of the United States not to put this terrible new weapon of indiscriminate mass destruction to actual military use. Others, like J.Robert Oppenheimer, took an active hand in planning on which cities to drop the first bomb. But after a brief flurry of organized, political effort following the war's end, most physicists had, by 1947, turned from politics back to science. Albert Einstein located the cause of his own discouragement in the apathetic response of the American people: 'The public, having been warned of the horrible nature of atomic warfare, has done nothing about it and to a large extent has dismissed the warning from its consciousness' (Jungk [5.33], 249).

Having mentioned Einstein, it is appropriate here to return to another important intellectual figure of the period, one who has until now been mentioned only in passing. However great his contributions to the development of analytic philosophy in the twentieth century, or to its intellectual life in general, Bertrand Russell's place within the history of early twentieth-century ethics remains problematic. As Bart Schultz notes in 'Bertrand Russell in Ethics and Politics' [5.64], Russell's writings on ethics, in particular, are no less remarkable than they are elliptical. Moreover, as intertwined as his views are with the main threads of the period's history, to that same extent is it difficult to weave them into any reasonably straightforward delineation of anything that might count as its warp or woof. Beginning as a Moorean objectivist in the early decades of the century, Russell soon sets off on his own emotivist tack, anticipating in a number of significant respects the later and more fully articulated views of not only Ayer, but Stevenson as well (Schultz [5.64], 597–9). But by at least 1952, Russell has already developed views that go off in another new direction, one which combines elements of emotivism and naturalism on the one hand, and utilitarianism and a social ideal of interests harmoniously arranged on the other (Russell [5.57]; Schultz [5.64], 603–4 and 613–14).

What is more interesting in the present context, however, is the breadth of Russell's own politically engaged life. In his voluminous writings addressed to a popular audience rather than to other professional philosophers, he wrestles with the dangers a well-developed set of sciences poses for society, and in particular, the ways in which technology may be effectively used to prevent people from thinking for themselves. Refusing himself to follow public opinion, which according to Russell could all too easily be manufactured to conform to the interests of those with social power, Russell was twice imprisoned: first for protesting Britain's involvement in World War I, and then again in 1961 for protesting British involvement in the nuclear arms race.

For those engaged in moral reflection at the close of the twentieth century, Russell's example is important in more ways than one. Technology and mass communication have, if anything, tightened their grip on free, democratic thought. And while the Cold War has at least temporarily abated, the threat of nuclear holocaust has hardly vanished: while the number of countries with nuclear capability continues to grow, the world itself continues to become increasingly more politically unstable. Third, and perhaps most important, we are now at a scientific and technological brink of our own. Just as few moral philosophers before 1945 could really have contemplated the possible annihilation of life as we know it, few

contemporary moral philosophers are really able to contemplate the enormity of the potential for changing the basic structures of life raised by the possibility of genetic engineering.

At mid-century, the basic structure of the atom was suddenly laid bare to science and technology. At the century's end, the basic structure of DNA promises to be similarly disclosed to human understanding and manipulation. As we prepare to enter the twenty-first century, it is hard to tell which of these events will have deeper and more far-reaching ramifications for moral thought and action.

LOOKING BACK

If early twentieth-century moral philosophy began with Moore's confident assertion that the good was a simple, non-natural quality of certain intellectually evident objects of moral knowledge, it most certainly ended with the emotivist claim that moral judgements did nothing more than express subjective feelings about right and wrong. In between, the world was witness to two major wars, the Nazi holocaust, and the United States' atomic annihilation of the Japanese cities of Nagasaki and Hiroshima. Yet it would be too simple to say that by 1945 science and ethics had finally and unequivocally parted ways. As one of the patients in the insane asylum of Friedrich Dürrenmatt's play *The Physicists* [5.17] points out, any one of us who passively flicks on an electric light without knowing the physics of what he or she is doing is guilty of abusing not only science, but humanity. As long as such passivity is our social norm, none of us is safe, not even, it turns out, a physicist who believes himself to have escaped from the insanity of a world in which atomic bombs are dropped on cities to the relative calm of a madhouse.

More poignant is Bertolt Brecht's *Galileo* [5.4]. This play's central moment of dramatic tension occurs when Galileo, under threat of torture, recants his rationally founded belief in the Copernican theory. According to his followers, Galileo has, as the great physicist of his day, failed both science and humanity. In publicly abandoning the scientific method, he has violated the onerous responsibility that attaches itself to the social role he finds himself, like it or not, thrust into; in publicly recanting, he has plunged humanity back into the darkness of ideology and the unbalanced social order which it enshrouds. As his main disciple shouts after him, 'Unhappy is the land that breeds no hero'. So too have many accused the physicists who produced the bomb of moral cowardice. To them we might recommend Galileo's own response, which is underscored by the counterpoint of the play's final scene: 'Unhappy is the land that needs a hero' (115). In its stubborn refusal to think for itself, it is humanity itself which has failed.

In this same connection, and in direct response to the is/ought dilemma, it is worth considering a point to which Dewey often returned: when ethics is banished to a separate, ethereal realm above and beyond science, hypothesis and action, the real world in which we must actually conduct our lives is left to the mercy of uncontrolled commercial and military interests. As he puts the point in *The Quest for Certainty,*

> [t]he narrow scope which moralists often give to morals, their isolation of some conduct as virtuous and vicious from other large ranges of conduct…is perpetuated by this habit of exclusion of the subject-matter of natural science from a role in the formation of moral standards and ideals. The same attitude operates in the other direction to keep natural science a technical specialty, and works unconsciously to encourage its use exclusively in regions where it can be turned to personal and class advantage, as in war and trade. ([5.14], 274)

In contrast, Dewey's naturalistic moral philosophy was closely connected to his concern over the social conditions produced by the capitalism of early twentieth-century North America. These included the exploitation of child labour, the creation and maintenance of utterly inhumane living and working standards

in cities and factories, and the coercive threat of unemployment that made such conditions inevitable and inescapable for large numbers of people.

Social unrest, socialist ferment, the progressive movement of which Dewey and other intellectuals were a part, trade unionism and subsequent government regulation all played a role in ameliorating such conditions, at least enough so that the growing threat of national chaos and social revolution could be nipped in the bud. But while nationally bounded capitalist concerns may thus have proved themselves to be controllable, it has become increasingly clear as the century has wound down that there is no controlling capitalism's Promethean capacity for escaping such bounds. In the face of national regulation of its concerns, capitalism has simply gone transnational with its conditions, relocating its child labour, starvation wages, unsafe working standards and shows of military force to the Third World. Moreover, as the standard of living consequently continues to fall in Canada, the United States and the United Kingdom, it is also becoming clear that if capitalism is indeed a great leveller of social differences, its natural grade favours Third World conditions over First.

In terms of ultimate influence, then, the work of Dewey and the other naturalists may turn out to be of the most lasting importance. In any social network where the many starve so that the few may overconsume, we may suppose, that is, that interests will not have been harmoniously arranged. As the early twenty-first century shapes up to be a transnational replay of the early twentieth-century conditions of Dewey's United States, we might thus allow ourselves the hope that a concern for ethics, rather than meta-ethics, will mark the dawn of the new century. Dewey's question, of course, would be what we, now, might do in pursuit of that hope.

CHAPTER 6
Ethics II (1945 to the present)

Robert L.Arrington

In the years immediately following World War II, the field of ethics was dominated by discussion of the meta-ethical theory known as emotivism. This theory maintained that moral judgements are expressions of emotions and attitudes and not statements of fact about objective reality. As a set of claims about the meaning and the epistemological status of moral judgements, emotivism represented a new, metaethical conception of ethics. Earlier in the century G.E.Moore had inquired about the meaning of the word 'good', and hence he and his fellow British intuitionists might be said to have initiated the metaethical approach. But it was the emotivists who first restricted ethical inquiry to meta-ethical investigations. Rather than making normative judgements about what is right and wrong or good and evil, they saw the role of philosophy as one of elucidating the linguistic character of normative judgements. Questions of meaning and justification were central to the emotivists' conception of meta-ethics as a second-order enterprise of linguistic analysis. According to this conception, no first-order, normative conclusions follow from meta-ethical analyses. Understood in this sense, meta-ethics became the preferred way of doing ethics for the following two decades.

The theory of emotivism was first proposed by several philosophers identified with logical positivism, the influential philosophy of the 1920s and 1930s whose main thrust was to articulate a criterion of meaningful speech and, in accordance with this criterion, to limit meaningful discourse to statements that are empirically verifiable. The positivists' verifiability criterion of meaningfulness in effect restricted meaningful discourse to scientific statements, from which domain the class of moral and ethical statements (as well as aesthetic and religious ones) was excluded. But if moral utterances are not meaningful statements about the world, about human beings and their actions, what are they? Rudolf Carnap suggested that they are not statements at all but rather commands: to say, for example, that stealing is wrong is just a way of ordering someone not to steal. In a similar vein, A.J.Ayer maintained that the real function of moral and ethical remarks is to give vent to the feelings and emotions of the person making the remarks —hence 'stealing is wrong' is another way of saying 'Stealing, ugh!' Clearly, commands and exclamations are not factual statements at all, and they cannot be thought of as true or false (although an expression of emotion can be insincere). Hence they do not convey any form of knowledge. Moral judgements, according to this way of thinking, are non-cognitive. Instead of imparting information and knowledge about human nature and human action, moral utterances are emotive in function, aimed at expressing affective states or influencing attitudes and actions. Hence the appropriateness of referring to this view as the emotive theory of ethics.

Charles L.Stevenson's *Ethics and Language,* published in 1944, is undoubtedly the most sophisticated and elaborate development of emotivism. Stevenson was interested in explaining why there is so much moral disagreement and why this disagreement is often so difficult to overcome. If, as naturalistic moral philosophers maintained, moral terms refer to natural properties detectable by the use of scientific method,

the moral judgements containing them should be subject to empirical verification or falsification. If naturalism were true, the processes of scientific inquiry should be adequate to establish the truth of moral propositions to the satisfaction of all rational minds. Likewise, if moral judgements make reference to non-natural qualities detectable by a special sense of moral intuition (as the intuitionists had claimed earlier), the exercise of this allegedly cognitive capacity should lead to the resolution of moral disagreements. Or, finally, if philosophers like Kant were correct and there is some rational, quasi-logical decision procedure that is to be applied to moral decision-making, then rational human beings should be able to come to agreement over moral truth. But disagreement is rampant and unceasing. Why is this so? Have our scientific, intuitive or rational decision procedures not been properly applied? Or is moral disagreement perhaps not something that is always amenable to cognitive resolution?

Stevenson was impressed by the fact that moral disagreements and arguments are highly dynamic affairs —the parties to the disputes are trying, it appears, not just to get their opponents to believe something different, but to *feel* and *act* differently. The language used in the debates is emotively charged: the words 'good' and 'bad', 'right' and 'wrong' appear to express positive and negative feelings and attitudes on the part of the speakers, and these and other emotionally potent words also seem to serve as instruments which the disputants use to influence one another and to goad one another into action.

Stevenson shows how, to his mind, these attitudes and activities are built into the very meanings of moral terms and judgements. The latter, he maintains, have both emotive and descriptive meaning—they serve to express and evince or evoke attitudes as well as to make descriptive claims. The word 'good', for instance, is often used by a person to describe herself as approving of some object or action, but at the same time it is used dynamically to *express* the speaker's pro-attitude to the object. Finally, it is also used to call on the person spoken to to approve of the object or action as well. Hence, according to Stevenson, '*x* is good' often means something like 'I approve of *x,* do so as well.' 'Good' at one and the same time describes the speaker as approving of the object (just as she might describe herself as five feet tall), expresses the speaker's approval (much in the way in which 'Ouch!' expresses pain and 'Ugh!' expresses disgust) and urges others to approve of it (just as she might command someone to close a door).

Stevenson provides us with a sophisticated causal and dispositional analysis of the notion of meaning. In the first place, meaning is to be understood in terms of the conditions that give rise to an utterance, and also in terms of the conditions that are brought about as a result of this utterance. Frequently certain beliefs and attitudes will causally lead a person to use certain words, and the use of these words in turn often causes other people who hear or read them to come to have the same beliefs and attitudes. If I believe it is about to rain, this may cause me to say that it is about to rain, and my doing so in turn may lead others to believe this. If I disapprove of something my daughter has done, I may be led to say that what she did was wrong, and as a result of my saying so others (including, I hope, my daughter) will also come to disapprove of it. The meaning of what I say relates to the beliefs and attitudes that give rise to my utterances and are in turn caused by them.

The meaning of a word, however, is not just the set of ideas or attitudes that causes a person on a particular occasion to utter the word (or that on a particular occasion is produced in others by the utterance of the word). Such causes and effects are too variable to constitute meaning. But over an extended period of time, words, as a result of their use, develop a tendency to cause specific beliefs and attitudes in those who hear them, just as they develop a tendency to cause a person to say certain things. These tendencies may be referred to as dispositions, and these dispositions have a constancy which allows them to figure into an account of meaning. Thus Stevenson is led to think of the meaning of a word as its disposition to evoke a specific set of ideas and attitudes and its disposition to be used by a person who has these beliefs and attitudes.

Consequently, the meaning of a word like 'good' can be defined in terms of its dispositions vis-à-vis a specific set of attitudes and beliefs. One meaning it may have is its disposition to cause others to approve of an object and to believe that the speaker approves of it, together with its disposition to be used by a speaker when that speaker approves of the object. We may say that in such cases its *descriptive meaning* is its disposition to cause others to believe that the speaker approves of the object, while its *emotive meaning* is its disposition to express and evoke approval of the object. (Stevenson allows for a richer descriptive meaning as well, but the analysis just given captures the essential thrust of his theory.)

Given that moral judgements (and value judgements more generally) are functions of both beliefs and attitudes, understanding disagreements in the moral sphere requires grasping how these two components can come into conflict and how they can interact with one another. Two or more individuals may have a straightforward disagreement in belief: one believes that Clinton will win the 1996 presidential election and the other believes that Dole will do so. Or they may have a disagreement in attitude: one approves of Dole and the other heartily disapproves of him. More often than not, the disagreement in belief can be conclusively resolved: either Clinton or Dole will win the election and one party to the dispute will be correct and the other wrong. It is slightly more complicated in the case of disagreement in attitude. Many, perhaps most, disagreements in attitude are the result of disagreements in belief. Two potential voters may have different attitudes about Clinton because they have different opinions about what his policies would be if he were elected president. They may debate the issue of what his policies would be, and one of them may succeed in changing the other's mind. And this may lead the other person to develop a new attitude towards Clinton: agreement in belief would lead to agreement in attitude. But such a functional relationship need not always hold. Two individuals may agree in belief to the effect that Dole favours a widespread cut in the capital gains tax and Clinton does not. One of the individuals, however, approves of Clinton because of his position on this issue; the other disapproves of him for the very same reason. Here we would have a disagreement in attitude that, at least on the surface, is not based on a disagreement in belief and cannot be resolved by bringing about agreement in belief (it is possible, of course, that the two parties to the dispute have *other* disagreements in belief—perhaps about the general nature of society and the economy —which are ultimately responsible for their conflicting attitudes towards the capital gains tax). Hence it is conceivable that there may be disagreements in attitude which are independent of disagreements in belief. If so, they would not be resolvable by attaining agreement in belief.

The dual—emotive and descriptive—meaning of value judgements together with the different possibilities for agreement and disagreement in attitude and belief lead Stevenson to conclude that there is a limit to the effectiveness of rational debate in the moral sphere. To the extent that moral disagreements reflect disagreements in attitude that are based on disagreements in belief, these moral disagreements are potentially resolvable by rational means, namely those empirical and logical techniques used to bring about agreement in belief. But to the extent that moral disagreements reflect attitudinal differences not based on differences of belief, rational means alone cannot guarantee agreement. In such cases, the use of reason, scientific method, and the like may bring all parties to agreement on the facts, but their differing, belief-independent attitudes would remain in spite of this. Theoretically, then, there is a limit to what we can expect from the use of reason in the moral sphere.

Another important implication follows from Stevenson's emotive analysis of moral judgements. This analysis implies that the notion of validity does not apply in the case of many moral arguments. If the judgement 'Tom is a good person' means, as Stevenson suggests, 'I approve of Tom, do so as well', someone disagreeing with this judgement may be taken to say 'I disapprove of Tom, do so as well.' Finding themselves in disagreement, the two individuals, *A* and *B,* may proceed to argue with one another, and this argument would involve an attempt on the part of each person to bring forth information about Tom which

would hopefully change the other's beliefs and hence her attitudes towards Tom. Let us assume that one of the parties to the dispute, *A,* is successful in this way in winning over the other person, *B,* to the view that Tom is a good person. What would be the relationship between all the reasons *A* gives in favour of 'Tom is a good person' and this normative conclusion itself? Is it possible that *A*'s reasons have proved that Tom is a good person? Do we have here an argument in which the reasons constitute premises from which one might validly derive the conclusion that Tom is a good person?

Stevenson's answer is negative. The reasons given by *A* should not be seen as evidence in favour of *A*'s assertion that Tom is a good person. After all, this assertion amounts simply to *A*'s saying that she, *A,* approves of Tom together with her admonition that *B* do so as well. We may reasonably expect *B* to agree with the statement that *A* approves of Tom—that is not what is at issue, and hence not what *A* is trying to convince *B* of when she argues with her. The reasons provided by *A* are not, then, intended to prove *A*'s statement that Tom is a good person; rather, they are intended to change *B*'s beliefs about Tom and hence her attitudes towards him. They are either effective in doing so or not, and hence the only question that can be raised about these 'reasons' is whether they are causally effective in changing someone else's moral judgement, not whether they are rationally effective in proving the speaker's moral judgement. The notion of validity has no central place in moral debate (although, of course, it has a subsidiary role in determining whether the beliefs involved in the debate have been rationally defended).

The consequences of Stevenson's emotivism are shocking, at least to those who believe that reason has a central role to play in moral debate and that if it were used by all parties, rational agreement would in the end occur. Validity, the central component of the concept of rationality, turns out to have only a limited role to play in moral argumentation, and the threat of disagreements in attitude that are not rooted in disagreements in beliefs calls into question any general faith in the rational resolution of moral disagreements. Moreover, emotivism gives us a picture of moral discourse quite different from what we are commonsensically accustomed to. It pictures this discourse as a set of strategies for influencing, persuading, and on occasion goading people to develop desired sets of attitudes, not as a dispassionate search for truth. In this context, truth and validity count for little: agreement in attitude, by whatever means, seems the ultimate goal. When the guns of World War II grew silent, philosophical debate over the nature of morality began with a bang!

Although emotivism has a deep and wide sceptical appeal, many philosophers soon began to view this scepticism as based, as scepticism so often is, on a misunderstanding of the actual shape or form of our language, in this instance moral language. Some critics argued that the emotivists failed to make a necessary distinction between guiding a person's attitudes and actions and goading a person into feeling and acting in certain ways. Others expressed doubt over Stevenson's causal theory of meaning and insisted that we define the meanings of moral terms by reference to the linguistic rules governing ordinary discourse. Perhaps the greatest concern with emotivism was its derogation of reason in the moral sphere, its claim that the concept of validity has no central application in moral argumentation. This claim seems to fly in the face of our frequent criticisms of the moral arguments of others and our own efforts to make our moral convictions as well grounded as possible. Thus began a revolt against emotivism, the first major critics being advocates of the meta-ethical theory of prescriptivism.

The philosopher primarily associated with prescriptivism is R.M. Hare. His book *The Language of Morals,* published in 1952, is a landmark in twentieth-century moral theory. It puts forth a position that continues to be held today by many philosophers. Although critical of emotivism, Hare's prescriptivism remains a non-cognitivist theory. It shows, however, a greater sensitivity to the actual use of moral language.

Hare was one of those thinkers concerned that emotivism gave too little acknowledgement to the role of reason and logic in moral argumentation. Once we grasp the structure of such an argument, he thinks, we will see that it often has the form of a syllogism. Consequently the rules of valid reasoning can be strictly applied to it. Consider this example of a moral argument:

A: It was wrong of Mary to have an abortion.
B: Why?
A: Because it involved the taking of a human life.
B: Why does that make it wrong?
A: Because it is always wrong to take a human life.

This argument can be turned around to reveal the following syllogism:

1 It is always wrong to take a human life.
2 In having an abortion, Mary was taking a human life.
3 It was wrong of Mary to have an abortion.

This is a perfectly valid argument and hence proves its point as forcefully as possible. But, as with all valid arguments, one is required logically to accept the conclusion only if one accepts the premises. Hence a debate may break out over whether it *is* always wrong to take a human life. In this debate, a defender of premise (1) may construct another syllogistic argument which looks like this:

4 It is always wrong to disobey the commandments of God (which include the commandment not to kill).
5 Taking a human life is disobeying one of the commandments of God.
6 It is always wrong to take a human life.

Whatever else one may say about it, this extended argument has logically impeccable credentials. If there are reasons to be sceptical about moral argumentation, *reason itself* cannot be faulted. The concept of validity, according to Hare, applies in morality as much as in other spheres.

The examples just considered suggest that moral justification ultimately leads to basic or fundamental moral principles which are not themselves susceptible of the type of proof they help generate for less basic principles and particular moral judgements. Consider premise (4): it is always wrong to disobey the commandments of God. In the minds of many believers, this principle is ultimate—there are no other principles from which it itself is deductively derived. What if another person does not accept this principle? Perhaps that person does not even believe in the existence of God, in which case she surely will not agree that one ought to obey God's commandments. If moral arguments have the deductive structure that Hare describes, and if in the course of an argument we arrive at an ultimate principle, in the nature of the case no further deductive justification can be given for the ultimate principle. Thus there is no way to prove this principle to someone who does not accept it.

Hence we must say that while Hare shows us that reason has an important and central role to play in moral disputation, his analysis suggests that there is a limit to the ability of reason to bring about rational moral agreement. In defending our particular moral judgements and most of our principles, we must abide by the canons of logic. But reason and logic will bring about agreement on moral matters among people only if they accept the same ultimate principles. It may not always be clear whether or not people do accept the same ones, but the possibility of irreconcilable disagreement over such principles seems an inescapable sceptical implication of Hare's analysis. It leads us to question whether reason can be said to prove any of

our moral judgements (if all of them finally rest on unproved ultimate premises), and thus it leads us to doubt whether we can really claim knowledge of our moral convictions.

The non-cognitivism inherent in Hare's meta-ethics becomes even more apparent as we attend to his analysis of the role or function of moral judgements. Moral judgements, according to Hare, are prescriptive, quasi-imperative in nature. Prescriptions cannot be true or false, and it makes little sense to talk of knowing them. Although I may know that someone commanded me to close the door, it is senseless to say I know the truth of the command 'Close the door'. The prescriptive status of moral judgements precludes the possibility of moral knowledge, in spite of the fact that, according to Hare, reason requires that we be consistent in our use of moral prescriptions.

Taking the word 'good' as the focus of his prescriptive analysis of moral language, Hare reminds us that it is a word of commendation. As such, it is used to commend things in situations of choice. If I say that the new Honda is a good car, I am recommending that someone, perhaps I myself, buy one. I am guiding someone's choice of a car. If I say that Gandhi was a good person, I am commending the kind of life he led and recommending that others emulate this life. The function of commendation in these examples can be characterized in prescriptive terms—I am prescribing the choice of the new Honda, or the way of life exemplified by Gandhi. I am answering the questions: What shall I choose? What shall I do? Contrary to emotivism, Hare claims, the function of a value judgement is not to get someone (causally) to do something or have a certain attitude but rather to tell her to do it. In telling someone this, I use prescriptive language.

I am not, however, just arbitrarily prescribing choices. In saying that something is a good car or life, etc., I imply, according to Hare, that there are good reasons for choosing this kind of car or life. I imply that the objects commended have certain properties that make them good and in virtue of which I commend them. These properties Hare calls the good-making properties of the class of objects into which the one I am commending falls, e.g. the good-making properties of cars, or of human lives. It is always appropriate, Hare insists, to demand of someone commending a certain object, person or action that she provide reasons for this commendation, and these reasons should refer to the good-making properties of the object.

In articulating the good-making properties of a class of objects into which the commended entity falls, I am in effect appealing to a universal standard or principle, e.g. 'Good cars have properties *a, b* and *c*' or 'Good lives have properties *f* and *g*.' My particular value judgement always implies a universal value judgement. This universal standard or principle, together with a statement to the effect that the entity I am commending in fact *has* the appropriate good-making characteristics, yields the value judgement that I initially made. Hence:

7 Good cars have properties *a, b* and *c*.
8 This new Honda has *a, b* and *c*.
9 This new Honda is a good car.

How are we to characterize the universal standard or principle that serves as the major premise in arguments of this sort? It too, Hare thinks, must be seen as prescriptive. Just as in saying the new Honda is a good car I was prescribing its choice, so in saying that cars with properties *a, b* and *c* are good cars I am commending, and prescribing for choice, cars having these properties. General principles are no less prescriptive than the particular moral judgements falling under them.

Hare's thesis concerning the commendatory, prescriptive nature of value terms and judgements and his claim about good-making properties allow him to maintain that moral terms and judgements have both evaluative and descriptive meaning. The commendatory function or prescriptive role can be called the evaluative meaning of a moral term or judgement; the implied statement about the good-making properties

of the object commended can be referred to as its descriptive meaning. Normally, moral terms and judgements have both evaluative and descriptive meaning. The evaluative meaning, however, is primary. It remains constant regardless of the class of object commended, while the descriptive meaning varies with this class. The primacy of the evaluative over the descriptive meaning also comes out in this way: unless I am willing to commend a certain set of properties for choice, I will not take them to be the good-making characteristics of the class of object in question.

Hare's claim that value judgements are prescriptive allows him to demonstrate the close connection between evaluation and action, a task which, he maintains, cannot be accomplished by those who interpret value judgements simply as descriptions. In accepting a value judgement, I am in fact assenting to the prescription to choose the object or perform the action in question. The criterion of assent to a prescription is that, other things being equal, I in fact do what the prescription tells me to do (in other words, I have not assented to the prescription unless, other things being equal, I perform the prescribed action). Of course, other things may not be equal: I may change my mind about assenting to the prescription, or find I cannot do what I am told to do, or forget what I was to do, etc. But if one or another of these conditions does not exist, assent to a prescription entails that I obey the prescription. Contrariwise, assent to a *description* never entails that I will perform a certain action; indeed, it never entails that I will do anything whatsoever. Hence Hare's analysis of practical discourse indicates why it is *practical,* why it issues in action. (One should note that the intimate relationship between prescriptions and actions also poses a major problem for Hare, the problem of weakness of the will. It certainly appears that I may assent to a prescription without any of the *ceteris paribus* conditions mentioned above holding and still fail to act—my will may be weak. Explaining this weakness of the will is a major problem for a prescriptivist.)

The commendatory function of 'good' and other value terms has an important logical consequence. Commending, we have seen, involves the prescription of choices. Prescriptions are logically distinct from descriptions and incapable of being logically derived from them alone. No matter what properties I describe a car as having, in describing it I have not taken the step of recommending that it be chosen: I have not said 'Choose this one.' Hence no prescriptive value judgement follows from premises that contain only true/false descriptions. We have seen that evaluative arguments contain not only a descriptive minor premise but also a prescriptive universal standard or principle as the major premise. We now can observe that this is the structure that a valid evaluative argument *must* have. A prescriptive conclusion follows from an appropriate prescriptive major premise and an appropriate descriptive minor premise, but not from the latter alone. And no matter how many factual, descriptive statements are added to the argument, the evaluative conclusion will not follow from them until such time as an appropriate prescriptive judgement is entered as a premise as well.

Important consequences for the issue of moral agreement follow from these logical observations. Agreement on facts will not by itself ensure agreement on a disputed moral judgement. Two or more people may operate with different moral standards or principles, in which case they may agree on all the properties of the object, person or action they are evaluating and still disagree on its moral or evaluative character. If they bring the same standards or principles to the discussion, agreement on the facts is to lead to agreement regarding the evaluative conclusion, but if they do not do so, they may find themselves in irresolvable disagreement. Of course, as noted above, they may attempt to obtain agreement on the standards or principles by arguing for them. But this argument must have, as we have seen, another standard or principle of greater generality as its major premise, and unless two or more people can agree on such a major premise of higher generality, they will not obtain agreement on standards or principles of lesser generality. In so far as no evaluative judgement can be deduced from factual statements alone, ultimate principles must be seen as based on fundamental commitments or decisions of those who hold them. If people

have made commitments to different standards or principles of highest generality, there will be no way in which one of them can be compelled logically or rationally to adopt a different basic principle.

Hare seems willing to accept these consequences, but he thinks they imply no basic arbitrariness in the area of moral discourse. Moral discourse is such that moral judgements conceptually require that reasons be given to support them. In tracing out the series of factual claims and standards or principles supporting a moral judgement, in pointing to the consequences of following these standards or principles and showing how doing so satisfies even higher, more ultimate principles, one is in effect revealing a way of life. To be able to articulate this way of life in defending a moral claim is to be a fully rational creature. To ask for more, to demand that we be able to justify the way of life by deducing it from some set of factual propositions, is to ignore the fact that morality is a matter, not ultimately of the world being a certain way, but of our choosing to live a certain kind of life.

Hare's prescriptivism dominated discussion in moral philosophy during the 1950s and 1960s, and it quickly became the paradigm of non-cognitivist approaches to moral discourse. But reaction against prescriptivism began in the late 1950s and picked up steam in the 1960s. Although no competing theory gained the position of dominance attained by Hare's prescriptivism, a number of powerful technical arguments were directed against it. Slowly, as a result of this attack, the pendulum began to swing back in the direction of cognitivism. To this day, however, no cognitivist position has attained the level of consensus that Hare's views previously attained.

A leader in the attack on prescriptivism was the Oxford philosopher Philippa Foot. In two pioneering articles, 'Moral Arguments' [6.8] and 'Moral Beliefs' [6.9], published in 1958 and 1959, she set out a form of moral philosophy that has been called neonaturalism, the central idea of which is that moral claims relate intrinsically or conceptually to the notion of human well-being. Consequently, these claims can be evaluated for their truth or falsity, and we can achieve an understanding of what really is right and wrong by understanding how our actions impact on human well-being. Our attention here will be directed primarily at Foot's reasons for opposing prescriptivism, for these reasons in the end have been more influential than her own constructive theory.

Foot objects to the idea that we can create criteria for the goodness of objects or the rightness of actions simply by approving of or deciding to commend a set of properties possessed by these things. Hare's view, she claims, would allow us to identify the class of good men as those with red hair, simply by virtue of our approving of and commending red hair. We could think it right to be cruel, just by deciding to prescribe the choice of cruel actions. To claim that good men are those with red hair, and right actions those that are cruel, is not, however, merely to make false claims. Such statements are absurd; they are conceptual nonsense. The proper use of words is defined by the rules of language, and the rules governing 'good' and 'right' do not allow us to apply them, respectively, to red-headed persons exclusively and to cruel actions. These rules prohibit us from using moral terms as we please. Hare made the descriptive meaning of moral terms dependent on their evaluative meaning: the good-making properties of a certain class of objects are the set of properties we decide to commend for choice. Such a view would allow the descriptive meaning to vary widely from one person to another. Foot thinks such a view implies conceptual anarchy, and she rejects this anarchy as inconsistent with the rule-guided nature of moral terminology. When we look to see what these rules are, we will find, she thinks, that moral terms are conceptually linked to certain sets of properties related to well-being. We cannot, without talking nonsense, use these terms in ways that do not acknowledge these conceptual links.

Another leader in the assault on non-cognitivism was Peter Geach. In 'Good and Evil', Geach argues that in phrases such as 'good person' or 'good auto' the term 'good' is being used attributively, not predicatively [6.12]. If its use were predicative, it would have a sense that could be understood independently of the

senses of the terms with which it is combined in these phrases, just as 'red' can be understood independently of 'cat' when it occurs in the phrase 'red cat'. A red cat is something that is red and that is also a cat. Hare's claim that the evaluative meaning of 'good' is independent of its criteria of application or descriptive meaning, and his assertion that the evaluative meaning is primary because it is constant across classes of objects having different criteria, requires that 'good' in 'good person' or 'good car' be taken as predicative. Geach argues that, on the contrary, its use in phrases of this sort is attributive. Take the case, he urges, of 'a good burglar'—this is not a person who is good and who is also a burglar. Understanding 'good burglar' requires understanding the meaning of the phrase as a whole—we do not know what 'good' means in this context unless we know what a burglar is. Hence we cannot postulate in this and similar cases an evaluative meaning of 'good' that is independent of the descriptive meaning of the term to which the normative term is attached.

In another influential essay, 'Assertion', Geach tries to show that the meaning of 'good' cannot be understood in terms of its commendatory use [6.11]. He points to numerous sentential contexts in which the use of this word cannot be taken to commend anything, e.g. 'If the child is good, she should be allowed to go out to play.' In saying, 'If the child is good…' one is certainly not commending the child. The meaning of 'good' in this context cannot, then, be explained in terms of its commendatory function or force. But, Geach goes on to argue, the term must have the same meaning in this context as it does in others if we are to preserve the validity of arguments in which it occurs. Take, for instance, the following argument:

If the child is good, she may go out to play.
The child is good.
Therefore the child may go out to play.

If the meaning of 'good' in the first premise were different from its meaning in the second premise, this argument would be invalid; it would commit the fallacy of equivocation. The argument, however, is valid. It follows that, in so far as 'good' in the first premise does not have a meaning connected to the role of commendation, neither does it have this kind of meaning in the second premise. Geach grants that terms like 'good' may on occasion be used to commend—this fact, however, does not preclude it from having a primary descriptive meaning which it contributes to the propositions in which it occurs, in *whatever* context these propositions occur.

Another influential attack on meta-ethical views similar to Hare's came from John Searle in his article 'How to derive "Ought" from "Is"' [6.16]. Searle argues that, contrary to a long tradition of thinking descending from Hume and captured in Hare's prescriptivism, it *is* possible to derive an evaluative judgement (about what one *ought* to do) from a purely descriptive one (about what *is* the case). Take the following descriptive remark: 'John uttered the words "I hereby promise to pay you, Smith, five dollars."' From this, Searle claims, we can derive the evaluative conclusion 'John ought to pay Smith five dollars.' Admittedly there are some intermediary steps that have to be filled in between the premise and the conclusion, but Searle maintains that none of them contains any evaluative statements or principles. The ought-statement, therefore, follows from the is-statements or descriptive premises alone. Searle's argument is controversial, but it has an initial plausibility that forced many philosophers to rethink the 'is/ ought' controversy. It led them to reconsider whether, as Hare alleged, prescriptions cannot be derived solely from descriptive premises, or even more fundamentally, whether ought-judgements and other evaluative claims really are non-descriptive (at least in any important sense).

Still other criticisms can be levelled at Hare and the non-cognitivist approach that his views exemplified. An important part of Hare's metaethical theory is the assumption that moral justification proceeds by

deducing particular moral judgements from universal standards or principles together with statements of fact that serve to subsume the particular judgements under the universal principles. We are not justified in accepting a particular judgement unless it is capable of being subsumed in this measure under one of our universal moral commitments. But why, some philosophers such as Renford Bambrough [6.7] and Jerome Schneewind [6.15] ask, do general principles have this justificatory priority? In fact, do they always have it in our everyday moral practices? It can be argued that we often feel far more certain that a particular act is wrong than we do about the general principle it instantiates. For example, it would certainly be wrong of me to break my promise to repay Jones five dollars in most ordinary circumstances, but would it always be wrong to break such a promise? We can think of many instances in which it might not be. Surely I should break a promise in order to save a life, and sometimes breaking a promise to promote a higher good seems perfectly permissible. Promise-keeping in some individual cases may have overriding weight, but in others it may not. Epistemically, we are far more certain of the duty to break a particular promise in special circumstances than we are of the principle that universally prescribes promise-keeping.

In fact, it could be argued that we actually arrive at many of our general moral principles by something like induction—because doing *x* was the right thing to do in so many particular circumstances, we generalize to the effect that doing *x* is always right. Such a generalization should be seen more as a guideline than as an absolute principle and should be held with considerable caution. As an absolute principle, it would be subject to refutation in a particular instance if we had a confident sense (some might say intuition) that it was wrong to do *x* on this occasion.

A sophisticated development of this latter mode of thinking has been developed by John Rawls. In fact, Rawls's proposed method of *reflective equilibrium* has become an attractive approach to the issue of moral reasoning for many philosophers today. Any attempt to arrive at a set of general principles (Rawls's own search is for principles of justice) must initially be tested by comparing, on the one hand, what a set of proposed general principles suggests we do, with, on the other, our own particular judgements or intuitions about what to do in specific circumstances, especially those judgements in which we have a high degree of confidence. The applications of the principles need to match up with these intuitions. Of course, we are not always so confident about what, in particular circumstances, we ought to do—and we can continue to put the proposed principles to the test by seeing if they can give us guidelines that we find we can accept in these problematic circumstances. Indeed, once we come to have considered confidence in our proposed principles—because of the way they match the deliverances of intuition and the way they provide acceptable guidelines in problematic situations—we may extend their use and actually use them to *correct* the deliverances of intuition. That is to say, after considerable testing, general principles may be used to overturn particular judgements we are inclined to mate when these judgements are unguided by general principles. In this way, our principles can come to correct our particular beliefs just as our particular beliefs can function to correct our principles. The end result of this process of mutual adjustment is that we bring our principles and particular judgements into a state of reflective equilibrium. Such a state bestows on both the considered principles and the considered judgements a level of epistemic warrant that is superior to the warrant either of these possessed at earlier stages in the process.

The method of reflective equilibrium appears to resemble in some important ways the method used in science to arrive at warranted beliefs. The development of general scientific theory is driven in part by particular observations, and concurrence with these observations is the test that general theoretical statements or statements of laws must pass. But once we have in hand a theory with some warrant, we can begin to use it to predict new observations, and we can even use it to reject observations that appear aberrant in light of the theory. In science, then, we seek reflective equilibrium between particular observations and general theory. If Rawls is correct, this is what we do in moral inquiry as well. Hence it is not difficult to

think of moral inquiry as much closer in nature to scientific thought than the emotivists or prescriptivists believed. The parallels we have noted appear to bestow on moral thought a degree of cognitivity and credibility that was denied it by the non-cognitivists. Rather than constituting a distinct mode of discourse that fundamentally expresses non-cognitive states of mind, moral judgements may reflect something like scientific method applied to a distinctive area of human experience. Again, the pendulum begins to swing from non-cognitivism to cognitivism.

Questions about the conceptual constraints on moral judgements and arguments about the nature of moral inquiry and methodology were part of a more general interest in the notion of morality itself. What is this area of experience and discourse we call morality? If we obtain a clear picture of it, we may see that morality deals with very distinctive concerns and questions which limit the kinds of considerations and reasons that can properly occur in a moral argument. Further, the very concept of morality may set limits on what kinds of actions can be judged right and what kind of people good. Rather than being matters of individual choice or attitude, as the non-cognitivists maintained, they may be identified fairly precisely by the requirements imposed by the concept of morality.

But what is built into the concept of morality? What distinctive concerns are moral ones? What dimensions of action and the world are morally relevant? A lengthy debate ensued over these issues, one party claiming that the concept of morality makes certain kinds of factual issues relevant and decisive for moral debate, the other party denying that the concept of morality imposes any material conditions of this type. The latter group of thinkers granted that the term ‘morality’ has a distinctive meaning, but for them this meaning reflects the distinctive *form* of moral judgements, e.g. their prescriptive nature and their universal or universalizable character. While the first group proposed *material* conceptions of morality which identify a distinctive moral subject matter, the second group argued that the concept of morality imposes only *formal* conditions on what can be a moral judgement.

One of the most influential advocates of a material definition of ‘morality’ was William K.Frankena. In ‘The Concept of Morality,’ Frankena first puts forward for purposes of argument a formal definition of the term which he thinks captures the conceptions of his philosophical opponents [6.17]. This definition tells us that a person has a morality if and only if she accepts certain judgements and principles (a) that are prescriptive, (b) that she universalizes as being binding on all persons and (c) that she regards as definitive, overriding or supremely important. Frankena then offers as an alternative a material definition which states that a person has a morality only if she accepts judgements and principles that take into account the effects of her actions on others from the point of view of the other people themselves rather than from the point of view of her own self-interest.

The formalist definition would allow there to be conflicting moral principles, one of which supports a purely egoistic way of life while the other recommends actions that take the interests of others into account. The material definition would restrict moral principles to those that take the interests of others into account. If one accepts the material definition, then considerations about how an action affects the lives of others are *necessarily* relevant to deciding what one morally ought to do. But if one accepts the formal definition, one cannot determine from the meaning of ‘morality’ alone whether these considerations are relevant.

Frankena argues for the material conception of morality by (1) suggesting that it accords best with the way we actually use the term ‘morality’ and (2) rebutting the arguments of those who prefer the formalist definition. He is particularly concerned with R.M.Hare’s claim that if we build social constraints into the meaning of ‘morality’, we win the argument against the egoist by linguistic fiat. Any judgement about what ‘morality’ means, according to Hare, must leave open the substantive issues that separate the egoist from someone who promotes the interests of others. Frankena agrees that the substantive issues remain even if we adopt the material conception. We do not dispose of the egoist’s claim that we should always pursue self-

interest simply by pointing out that this position is not a moral one; in arguing with the egoist we confront the issue of why we should prefer the moral perspective to the non-moral one. Thus one can grant that a disagreement remains, without giving up one's idea that the notion of morality itself requires consideration of the interests of others. If the egoist insists that his position *is* a moral one, then the only appropriate response is to see if his arguments in favour of this claim are acceptable. The egoist may suggest that it is not contradictory to say that an action involving an utter disregard for other people is not wrong on moral grounds. Is this correct? Frankena thinks not.

Many philosophers have been concerned that a material definition might serve to make something like utilitarianism true by definition— a consequence perhaps acceptable to utilitarianism but not to the many thinkers who reject it and still consider themselves to be moralists. Frankena's material conception of morality, however, is sufficiently broad to include deontological theories that emphasize duties to others as well as those theories committed to a policy of maximizing the pleasure or happiness of the greatest number. It excludes from morality only such principles as those of pure egoism.

The debate over the proper conception of morality came to no definitive conclusion. Some agreed in principle with the formalist conception but rejected the requirement expressed in the third component of Frankena's rendition of it—the requirement that moral considerations be considered supremely authoritative. They claimed that religious, even personal, considerations may take priority over moral ones in the minds of some people without these people having made any conceptual errors. Other attempts were undertaken to shore up both the material and the formal conceptions so as to provide necessary and sufficient conditions for the proper use of the term 'morality'. But necessary and sufficient conditions for the use of almost any term are hard to come by, as the case in point amply demonstrates.

A development in moral philosophy parallel and related to the search for a definition of morality was the good-reasons approach to moral discourse. This approach was initially articulated by S.Toulmin in his *The Place of Reason in Ethics* [6.21] and by Kurt Baier in his *The Moral Point of View* [6.20]. Toulmin and Baier urge us to attend more to the kinds of reasons that are submitted in defence of a moral position or judgement than to the logical character or content of moral judgements themselves. If we do so, they assure us, we will note that some considerations are particularly relevant to moral discourse and debate. Reasons appealing to accepted rules that define duties are perfectly appropriate considerations in most instances. But these rules may conflict with one another, in which case we may need to appeal to the very function of morality, which is to co-ordinate our attitudes and actions in ways that maximize the possibilities for everyone's aims and desires being fulfilled. Good reasons, therefore, ultimately are those that speak to the manner in which an action promotes the goal of fulfilling everyone's desires and aims. (It is not difficult to see how a philosopher like Hare might detect here an attempt to introduce utilitarianism into morality by linguistic fiat.) Clearly there is a fact of the matter about the impact of actions on this end state, and hence appeal to good reasons may allow us to achieve moral truth and knowledge.

Kurt Baier attempted to strengthen the notion of good reasons by showing that certain considerations or reasons are such that it would be irrational not to take them into account. In an early essay, he argued that the fact that an action will bring pain to oneself is a relevant consideration and one that normally counts against engaging in the action. Of course, there may be other reasons favouring an action that brings pain to oneself, e.g. the action may be in the best interests of one's family, and these reasons may show that an action is right even though it brings pain to the agent. But if there are no such overriding reasons, the fact that an action brings pain to oneself is a conclusive reason not to do it. If a person engages in an action only on the grounds that it would bring pain to him, we would consider this person irrational. Hence, everything else being equal, the production of pain is an objectively good reason *not* to perform the action in question.

Having established to his satisfaction that there are such things as objectively good reasons for or against an action, Baier turns his attention to moral reasoning. His argument here involves showing that there is a distinctive moral point of view such that assuming this point of view amounts to seeing certain kinds of reasons as relevant to the determination of what is morally right or wrong. A person acts from the moral point of view when he acts on general principles and does not make exceptions for himself even when following these principles frustrates his own interests. Hence moral rules or principles are universal—binding on everyone, including the speaker. Furthermore, moral principles or rules must be meant to promote the good of everyone alike, i.e. to take into account and further the interests of all.

Baier goes on to argue that it is more rational to promote moral aims than to pursue aims that conflict with morality, e.g. selfish aims. Our very purpose in reasoning, he tells us, is to increase our satisfactions and decrease our frustrations as much as possible. From this it follows that if I enjoy doing something, and my doing so does not hurt anyone else, then I have a good reason to do it. My enjoying doing *x* is objectively a good reason for doing *x* in these cases because not to think of it as being a good reason would be perverse or mad. But if my doing *x* would harm someone else, the situation changes. Our moral rules forbid us to harm others, even if doing so is enjoyable to us. Moral rules override those of self-interest. But the fact that moral rules have priority over rules of self-interest is also rational. As Thomas Hobbes observed, if everyone followed the rules of self-interest, this would lead to a state of nature in which life for everyone is nasty, brutish and short. Such a situation is contrary to self-interest, and promoting it is contrary to reason. We are more rational to accept rules which override self-interest in those instances in which pursuing this self-interest would be harmful to others. Those moral rules which are for the good of all are therefore in the interest of everyone alike. It follows that, within a society in which we can expect others for the most part to follow the moral rules, the moral rules are recommended by reason. The moral point of view is thus the rational point of view.

This argument can certainly be criticized. For one thing, it is possible to develop sophisticated forms of egoism which appear to be as rational as morality, perhaps even more so. We will not, however, pursue the argument at this point, although some theories we consider later will take up the case in favour of morality. Suffice it to say that the good-reasons approach to ethics made the notion of rational action (and the very concept of rationality) a central one in much of the moral philosophy that followed. Many philosophers approach the subject matter of ethics by inquiring whether our notion of rationality will allow us to construct an objective defence of morality.

Before discussing some of these 'rationality' approaches to moral objectivity, let us consider another question that arises out of the attempts to define morality and the moral point of view. Assume that we have done so adequately—the question then presents itself: why should I be moral? Baier, as we have seen, thinks the answer is: because being moral is in accord with reason—because it is in everyone's interest to do so. Other philosophers disagree with this type of answer —not because they are egoists, but because they think it is the wrong *kind* of answer to the question. Whether morality is in anyone's interest or not, they would say, is irrelevant. One ought to be moral simply because it is the right thing to do. The alternative—acting in preference for one's own interest when doing so brings harm to others—is simply wrong and vicious. Once we know what we ought to do morally, doing anything that conflicts with this is forbidden by morality.

But, another philosopher might observe, to answer the question 'Why be moral?' in this way begs the question; it adduces moral reasons in favour of being moral. The question posed is not whether there are moral reasons for acting in a certain way, but whether there are reasons to choose the moral point of view over other points of view, particularly the self-interested point of view.

A defender of morality might reply: what you are asking is whether there is an egoistic reason for preferring morality to egoism. And given that morality, with its emphasis on the good for all, often requires sacrifices of us, the answer will probably be negative. But what does this show other than that morality and self-interest are often opposed, as we knew before the argument began. If by chance we ascertained that it *would* be in our self-interest to be moral, this is not a justification of morality that a moral person is likely to accept. A person should be moral because she recognizes the superiority of moral reasons over self-interested, egoistic ones. One isn't really acting morally if one does so for selfish reasons.

We have here what appears to be a standoff. We cannot justify being moral by appeal to moral reasons or by appeal to egoistic ones. Perhaps we cannot justify being moral at all. Perhaps our decision to throw in our lot with the moral way of life is arbitrary. Baier himself does not think so. He thinks that moral reasons are superior to selfish ones because they are more rational. Others have argued that morality is at least not unreasonable. It is time to examine some of the recent theories that focus on morality from the standpoint of rational choice.

The first such theory to be considered is that of John Rawls. And it must be said at the outset that the brief description offered of this theory can in no way convey the enormous impact it has had in contemporary ethics. Rawls is one of the major figures in post-World-War-II ethics, and his normative system has had considerable influence outside ethics: in social and political philosophy and indeed in the political sphere itself. We will view Rawls's attempt to define and defend a set of principles of justice simply as one attempt to show how the notion of rational choice can generate an ethical position.

Rawls's position first came to the attention of a large philosophical audience through his early essay, 'Justice as Fairness' [6.29]. Other articles followed, and then in 1971 there appeared the monumental *A Theory of Justice* [6.28]. In 'Justice as Fairness', Rawls suggested that we begin our inquiry into the principles of justice by asking ourselves what principles a group of people (ourselves) would accept if they were in a position of having to identify the ways in which their future lives together would be organized and regulated. What principles would they agree on? Each person might initially prefer principles that would benefit him or herself, even at the expense of others, but would on reflection recognize that such principles would not be accepted by others. What is needed is a technique for determining what principles would be accepted by all. This technique would have to ensure that the principles for organizing society would be viewed by each person as being to his or her advantage, for only then would each person agree to them. The technique offered by Rawls involves identifying an 'original position of equality' which we might take up, a position in which we are all equal with respect to selecting principles that would be to our advantage, and hence a position in which we can have some assurance that everyone would agree to the principles proposed.

Getting into this original position, for Rawls, requires placing ourselves behind a 'veil of ignorance' from which vantage point we do not know what our individual interests or talents are or what our position in society is or would be. Not knowing such details about ourselves, we would be unable to propose principles that are uniquely designed to benefit us, to serve our interests and position and to capitalize on our talents. If we assume only general knowledge about the basic goods for human beings and basic facts about human nature and society, the principles we select could only further our common interests, those resulting from our general nature and condition. Not knowing who we are or would be in the future, and hence how certain policies might uniquely benefit us as distinctive individuals, we would select principles that would benefit us regardless of who we turn out to be. We would not, for instance, select principles authorizing slavery, since we might turn out to be slaves; we would not select principles that benefit the wealthy, since we might turn out to be poor. We would, on the contrary, select principles that would benefit everyone, and certainly would benefit the worst off among us, for we might very well fall into that group. The principles selected in

this way behind a veil of ignorance are principles that could be accepted by all parties to the deliberations. It would be reasonable for everyone to agree to the principles that suggest themselves to those in the original position.

In defining the principles of justice—the principles for organizing and governing our lives—as those that people would agree to accept behind the veil of ignorance, Rawls is not saying that this type of pact was ever in fact entered into. The agreement he is talking about is a hypothetical one: what we *would* accept were we to put ourselves behind a veil of ignorance. We are not, therefore, committed to the implementation of some social contract into which we have entered earlier. But in so far as the hypothetical agreement is one we can envisage in thought, and in so far as the conditions imposed on the thought experiment guarantee that the results would benefit us regardless of who we are, then it would be reasonable for us to accept the principles identified and to implement them in our actual lives.

What principles would we accept behind the veil of ignorance? Rawls identifies two principles. The first requires that each person have the maximum liberty compatible with equal liberty for others. The liberties Rawls has in mind are political liberty, freedom of speech and assembly, liberty of conscience and freedom of thought, freedom of the person, and freedom from arbitrary arrest and seizure. The second principle deals with the distribution of the goods of nature and society and requires that these goods be equally distributed among all people, except in those circumstances in which an unequal distribution would be in the interest of everyone, including those who are the worst off with respect to material resources and powers. The second principle also requires equal opportunity or access with respect to positions of authority in society. If the two principles conflict with one another, the first is to have priority over the second. In arguing for these two principles, Rawls uses the method we have identified earlier as the strategy of seeking reflective equilibrium among our intuitions about what would be right and fair in particular instances and the general principles we propose. In defending two normative principles, Rawls also began the process of turning ethics away from its concentration on meta-ethical issues of meaning and justification and pointing it in the direction of its more traditional task of seeking the principles that define for us what really is right and good. His theory of justice is not just a major contribution to normative ethics; it is also responsible for making the project of normative ethics a legitimate and respectable one once again. In this latter role it promoted the development of numerous other normative theories and also supported the developing interest in practical or applied ethics, which began to seek normative answers to specific ethical problems that we face in society today.

Many philosophers have followed the lead of Rawls in defining the basic issues of ethics in terms of the question of what reason would say regarding the best way to satisfy our preferences and maximize our chances for well-being. Some have made even stronger claims about the verdict of reason. David Gauthier [6.26], for instance, has argued that opting for unfettered self-interest as opposed to a set of rules impartially acknowledging the interests of others would be irrational. Gauthier sees morality as a part of the theory of rational choice. Using the techniques of decision theory (which defines principles of rational choice under conditions of risk or uncertainty) and game theory (which considers choices made on the basis of expectations about how other agents will choose), he believes it can be demonstrated that one rationally ought to agree to those moral rules of impartiality which would require an occasional sacrifice of our own interests in order to promote impartially the interests of all concerned. Application of the theory of rational choice would show that constraining the pursuit of our own interests by the principles of impartiality is actually in our own interest, and, indeed, that we would be irrational not to agree to constrain our actions in such a way. Gauthier's work is clearly an extension of the perspective of Kurt Baier, which we discussed earlier.

Perhaps the most ambitious use of reason in recent ethics is found in the rationalist ethics of Alan Gewirth. Gewirth [6.27] believes that it is possible to prove a fundamental moral principle in the optimally strong sense of showing that anyone attempting to deny the principle would contradict herself. This fundamental principle, called by Gewirth the principle of generic consistency, requires that one act in accord with the generic rights of others as well as oneself, these generic rights being those to freedom and well-being. Gewirth gives a highly complex (and controversial) proof of the principle of generic consistency. The proof begins by showing that each of us, as an agent who acts with purposes and goals, must favour our own freedom and well-being, these being the conditions required for us to attain any of our particular goals or realize any of our purposes. Consequently, our freedom and well-being are *necessary goods* for each of us. Having established that we must acknowledge that our freedom and well-being are required in all of our actions, Gewirth further argues that we must assert our *rights* to freedom and well-being—otherwise, they would not be goods we *must* have. But if each of us is committed to our own rights to freedom and well-being, based on the fact that they are necessary conditions for the realization of the specific purposes and goals to which we are committed, we must grant that others, for whom freedom and well-being are also necessary goods, must also demand their freedom and well-being. If each of us demand our rights on such grounds, each of us must admit that all other persons are equally justified in demanding their rights on the same grounds. To deny that everyone has the rights to the generic goods would put us in the irrational position of allowing that we have these rights on these grounds but that others do not. This denial would amount, Gewirth argues, to an inescapable inconsistency. Thus we cannot, without contradicting ourselves, deny the truth of the principle of generic consistency. Here we have one of the strongest advocacies in the history of philosophy of the power of reason to prove the truth of a moral principle.

The good-reasons approach to ethics established early on by Toulmin and Baier leads, then, to contemporary views of the role of reason in ethics that attributes to reason the ability to offer objective proofs of moral truths. As we have seen, there are a variety of such views (and we have examined only a small representative sample), but all of them put the notion of rationality at the heart of ethical thinking. Such views, although immensely popular today, by no means exhaust contemporary approaches to ethics. We will now turn our attention to some contemporary perspectives that see 'rationalism' as a misguided form of moral philosophy.

An increasingly influential movement in contemporary ethics is that of moral realism. There are two different forms of this theory, one that is basically intuitionistic (and British) in nature, and one that emerges from the scientific realism that is very popular these days, especially in America. The two strands have in common the fact that their advocates believe in the reality of objective moral properties—properties of obligation, goodness, and so on—which attach to actions, people, and circumstances independently of human belief or desire. They also believe in our ability to grasp these properties and thereby attain objective moral knowledge. Their primary difference relates to their understanding of the cognitive ability yielding this knowledge. The intuitionists stress our perception-like ability to directly confront the fact that actions and agents have certain moral properties. The scientific realists maintain that a form of inquiry similar to scientific theorizing often results in knowledge of the moral character of actions and agents.

The intuitionistic realists suggest that we are not well served by pursuing ethical inquiry primarily with respect to such abstract notions as the right and the good. Rather, they think, we should look at very specific moral notions such as kindness and courage. We have no difficulty in ascertaining that a person is kind or courageous, and in so doing we are detecting moral characteristics. It makes perfect sense to say that we *see* that a person is kind or courageous. To be sure, our 'perception' of these qualities is always based on a perception of other qualities of the person or her actions: we see that a person is kind because she did *x* or *y,*

or courageous because she reacted to situation *s* in manner *r*. But the moral characteristic cannot be *reduced* to these other characteristics. Nevertheless, the latter constitute the ground or basis for the moral property. We directly confront the fact that a person is kind, although we may refer to her other characteristics (which may be non-moral) in giving our reasons for the moral claim. The moral property is said by the realists to supervene on the base property or properties. This relation of supervenience captures the notion that moral properties are not inferred from non-moral characteristics and must be directly confronted in moral awareness; it also stresses, however, the fact that moral characteristics are not independent of the specific detail of character and circumstance in which they are embedded. The intuitionistic realists emphasize the need to pay close attention to the specific detail and circumstances of each action, so that we may detect the moral character directly and also the base properties which give rise to it and afford us reasons for asserting its existence.

Many of the intuitionistic realists approach the issue of moral reality from a perspective they think reflects the philosophy of the later Wittgenstein. Rejecting any form of scientism that would attempt to reduce all discourse to scientific propositions, they claim that our ordinary language incorporates concepts of moral properties and moral knowledge. In coming to master this language (play the 'language-game' of morality), we develop an ability to apply moral terms on the basis of perceptual criteria. If we do so correctly on a particular occasion, we can be said to state a moral truth and to achieve moral knowledge. No mystery attaches to the perception of moral reality— the appearance of oddness disappears once we realize that moral concepts shape and inform perception no less than do scientific concepts. We learn to apply scientific concepts, and when we do so correctly we have scientific knowledge; we learn to apply moral concepts, and when we do so correctly we have moral knowledge. Our moral language-game contains conceptual articulations and rules which we appeal to in actually playing the game. Theories that deny us moral knowledge, or that equate it with naturalistic, scientific knowledge, have failed to grasp the true nature of moral language. And the rationalists and others who put rules at the centre of morality have likewise failed to see that the moral language-game is one of directly seeing, confronting or detecting the moral character of particular actions and individuals, not one of deducing moral truths from general rules.

Scientific moral realism is in many ways a thousand philosophical miles away from the intuitionistic version. Its advocates do stress, along with the intuitionists, that in ordinary language we often speak of the moral properties of actions and agents as real and objective. They also note that in this ordinary discourse we have no hesitation in claiming that these moral properties are causally responsible for what happens in the world: we say, for example, that an army's defeat was caused by the general's cowardice, or that a dictator's cruelty led to his downfall. Taking their license for talking this way from ordinary discourse, the scientific realists propose that we attempt to construct theories of individual behaviour and societal change that take into account the causal efficacy of moral properties. Such theories will posit moral properties as part of their explanatory apparatus. These theories can be tested in terms of their ability to explain the course of human behaviour and societal change. The reality of the moral properties posited in these theories is no more suspect than the reality of sub-atomic particles. We accept both because of the ability of the resultant theories to explain what would otherwise be puzzling aspects of the world. We are justified in affirming the reality of an objective moral domain because of the explanatory utility of moral concepts.

The appeal to reason or rational choice, to intuition, or to scientific theorizing are three contemporary ways in which philosophers attempt to demonstrate the nature and reality of objective moral knowledge. The prevalence of such theories shows how far ethics has come from the scepticism inherent in emotivism and prescriptivism. But not all philosophers have accepted the claim to objective moral knowledge. To be sure, most ethical thinkers today have given up non-cognitivism for some form of cognitivism—the view that we do have moral knowledge. But being a cognitivist does not require that one think moral truth is

objective, something independent of human attitudes and customs and available for inspection or demonstration by any normal human being. An option that remains, and that offers an attractive face to those who still feel the pull of moral scepticism, is relativism. Relativism has been with us since the earliest days of western philosophy, and it is still a viable option today. Relativism of some form or another seemed to be implied by the non-cognitivist positions of emotivism and prescriptivism. Even if these positions are rejected, as by and large they are today, there is still room for relativism in the current cognitivist environment. The theory has recently been given outstanding articulation and defence by two American philosophers, Gilbert Harman and David Wong.

In approaching any discussion of relativism, a basic distinction needs to be made between cultural and ethical relativism. Cultural relativism is the thesis that different cultures or societies have different moral codes; it is the denial that there are any moral values universally accepted by all people. As such, it is an empirical, scientific thesis (one often asserted by anthropologists) and not a philosophical one. Ethical relativism is a philosophical thesis: it claims that none of the numerous moral codes found in history can be validated as the true or correct code. This form of relativism is a repudiation of ethical absolutism, the claim that there are actions that are right or wrong for everyone, regardless of what beliefs they hold. Hence, according to the ethical relativist, what is right is only what is right *for you* in your society. Your moral code is valid for you, just as the moral codes of others are valid for them. None of them is valid or true for everyone.

Ethical relativists are often criticized for basing their philosophical, epistemological claim on the empirical thesis of cultural relativism. It does not, of course, follow from the fact that people have different moral beliefs that no one of these beliefs is superior to the others or that there are no universally valid, absolute moral principles. So, the critic argues, ethical relativism is based on a logical fallacy.

But it is not necessary to assert one's ethical relativism on the grounds that moral codes vary from society to society. The denial that there are moral codes valid for everyone can be asserted on different grounds, and an excellent example of such a theory is found in the work of Gilbert Harman. Harman [6.40] denies that it makes sense for us to affirm general principles identifying what it is morally right for all people to do. To tell someone that she morally ought to engage in some action is to presuppose that she accepts a principle enjoining this kind of action. If she does not accept such a principle, she has no reason to engage in the action, and if she has no reason to engage in it, then it is inappropriate for us to suggest that she ought to do so. It makes no sense, Harman tells us, for us to say that cannibals morally ought not to eat their victims, because, having no moral principle prohibiting this, they have no reason to abstain from the practice. Likewise, it is logically absurd for us to say that Hitler was morally wrong to attempt the extermination of the Jewish people. Not subscribing to a principle that proscribed genocide—being as he was beyond the moral pale—Hitler had no reason not to do so, and it is therefore empty for us to say that he morally ought not to have done so.

In general, when one makes an 'inner judgement' about what a person morally ought to do, one is making a judgement about the relationship between that person's principles and her actions. If these principles vary from person to person, as Harman thinks they obviously do, it follows that inner judgements are inappropriate when the person addressed does not subscribe to the principle justifying the judgement. Hence the nature of these inner judgements about what one morally ought to do prevents us from making the absolutist claim that all human beings morally ought to behave in certain ways.

David Wong's brand of relativism is of a more traditional nature [6.43]. He grants that there are true and false moral judgements but denies that any of them are true for all persons. To claim that a particular moral judgement is true, he maintains, is to say that the act it enjoins accords with the ideal standards or principles of one's group. If these standards vary from one group to another, then what moral judgements are true for

one group may not be true for another—the actions judged to be in accord with the standards of one society may not accord with the standards of another.

Wong is sensitive to the charge that relativism would allow any action whatsoever to be judged right or wrong, a charge often levelled by absolutists. But, as we have seen, for an action to be right, in Wong's relativism, it must accord with the *ideal* standards or principles of a group. These ideal standards are those that are held in light of relevant factual information and that cohere with the other standards of the group. Hence constraints are placed on what accepted standards can generate true moral judgements. A sensitivity to relevant factual information and to logical considerations would rule out some standards. Finally, acceptable standards must perform the job that moral standards in all societies are designed to accomplish: they must help to resolve personal and interpersonal conflicts. Not all standards will succeed in this task, and those that fail are excluded from the set of ideal standards. So, Wong argues, not just anything goes. Moral truth requires an acceptable set of moral standards or an acceptable moral system.

Still in all, Wong claims, there are multiple moral codes that equally meet the criteria of acceptability set out above. He gives us as examples the virtue-oriented morality of eastern cultures and the rights-oriented morality of western Europe. The moral codes of these two moral systems will generate conflicting true moral judgements, so that for an easterner it is right to do *x* and for a westerner it is wrong to do *x*. For example, given the virtue-oriented morality's emphasis on the common good and the rights-centred morality's emphasis on individual liberties, the two moralities might conflict with regard to whether a person should contribute to the common good or pursue her own interests. Given the equal acceptability of the two moral codes, we are left with an ineradicable relativity of moral truth.

No account of the field of ethics since 1945 would be complete without an acknowledgement of the re-emergence of interest in two traditional ethical theories: utilitarianism and virtue ethics. Contemporary utilitarianism is an attempt to expand upon, refine and, according to some, radically alter the utilitarian views that were prevalent in the eighteenth, nineteenth and early twentieth centuries, particularly those of Jeremy Bentham and John Stuart Mill. Virtue ethics has a more ancient heritage: the philosophy of Aristotle. We shall conclude this chapter with a brief discussion of these two resurrected theories.

Utilitarianism, as articulated in the classical accounts of Bentham and Mill, is a theory which defines right actions as those that are productive of the overall greatest good. Such a theory is often characterized as ideological in nature: it defines right action in terms of the consequences of the action. Theorists may differ as to what constitutes good consequences—some say pleasure, others the avoidance of pain, still others happiness, and some few identify a plurality of ideals which right actions may produce. But all agree that what we ought to do is to engage in the action that produces more good than any other alternative action would produce. To produce the greater good is to have what is called utility. Right actions are those possessing utility.

Contemporary interest in utilitarianism has largely focused on the question whether the rightness of actions is a function of the consequences of the individual action itself or of the class of actions—the general kind of action—to which the individual instance belongs. Those who opt for the first form of the theory adopt what is called act utilitarianism, while those opting for the second form accept what is referred to as rule utilitarianism. To illustrate the difference in terms of an example, take the case of keeping a promise. For an act utilitarian, I should keep a promise I have made on a particular occasion only if in doing so I would thereby bring about better consequences—more happiness, say—than I would if I failed to keep the promise. It is perfectly conceivable that keeping the promise might *not* bring about more good than failing to keep it, in which case the act utilitarian would say that in those circumstances I should not keep it. This possibility disturbs some utilitarians and has led them to opt for rule utilitarianism. The rule utilitarian will say that I should keep the particular promise I made because it is enjoined by a general rule of promise keeping

('one should always keep one's promises'), and adherence to this rule brings about better consequences than making exceptions to it or abandoning it altogether. The rule utilitarian might agree that on a particular occasion my breaking my promise might produce better consequences than keeping it, but she will still insist on the rule's being followed because it is more desirable to have and follow the rule than not to do so. The act utilitarian thinks that such allegiance to rules, even those that have proved in general to be productive of good consequences, is irrational. If, on a particular occasion, I know that breaking my promise will bring about more happiness than keeping it, reason demands that I break it.

The debate that we see beginning to emerge between rule and act utilitarians has been one of the central features of contemporary discussions of utilitarianism. Another central feature relates to the conception of rules themselves. As a result of John Rawls's classic essay 'Two Concepts of Rules' [6.45], philosophers today distinguish between a summary and a practice or constitutive conception of rules. The summary conception is a statistical one: to say that promise-keeping as a rule has utility (produces better consequences than the alternatives) is to say that more often than not keeping promises turns out to be beneficial. The possibility of an exception is built into the summary conception, according to which a rule or principle should be put forward only as a guideline, to be followed more often than not. The practice conception pictures a rule, not as a statistical frequency but as a way of defining a certain kind of activity or organization. Chess rules afford us an example here. To say that the king cannot be captured is not to say that the king has not, as a matter of fact, ever been captured or that the king almost always escapes capture. The king, by definition, cannot be captured—such status is in part what makes the piece a king. The rule of chess that disallows capture of the king is a constitutive rule, not just a summary one. Likewise, in our society we find many rules that define certain forms of activity—what we might call practices. The practice of punishment is an example. The rules of punishment, for instance the rule that we are not to punish the innocent, are not summary rules but constitutive ones. They define for us what a practice like punishment is. Within a society that has a constitutive rule prohibiting punishment of the innocent, we do not examine individual instances of actions that would violate this rule to see if they might possibly have utility. To be engaged in punishment at all requires following this rule—otherwise what we are engaged in is simply not punishment. But the practice of punishment, with its constitutive rules prohibiting the punishment of the innocent and so on, might itself be examined to see if it has utility. If it does, it can be pronounced justified. The actions falling under the constitutive rules then are justified not because they themselves have utility but because the practice containing the constitutive rules does. Hence by construing rules as constitutive, many rule utilitarians are able to give additional substance to their form of utilitarianism. And they are able to save utilitarianism from the frequent charge that it would permit such morally heinous acts as punishing an innocent person on a particular occasion because doing so has utility.

As we noted, the current interest in virtue ethics amounts to a revival of something like Aristotle's conception of ethics. Instead of concentrating on general rules of duty, obligation and right action, Aristotle thought of ethics as an attempt to identify the features of character that are essential for achieving the good life for humankind. These excellencies of character he called virtues, and he set out to define them and show the manner in which they produce the good life. Of particular importance to Aristotle were those virtues that relate to our activities as citizens. The good life can be found only within society, and developing the civic virtues is essential for full and rewarding participation in the social sphere. Aristotle was suspicious of absolute, hard-bound rules. Frequently they require actions that are inconsistent with a proper, virtuous response to our loved ones and fellow citizens. In implementing the life of the virtues we are not so much to follow rules as pay close attention to specific cases. Frequently, becoming a good person is best achieved by emulating the example of a good person.

All these themes have found favour with some contemporary philosophers who are frustrated by the unresolved debates in meta-ethics and, more recently, dissatisfied with the current attention so often given to rules and their justification. The leader in the renewal of virtue ethics is Alasdair MacIntyre, whose book *After Virtue* [6.4] is one of the most discussed works in ethics in recent times. MacIntyre believes that contemporary moral philosophy has not overcome the nihilism and scepticism of Nietzsche, which he sees embodied in such contemporary views as emotivism. Unfortunately, however, those who eschew emotivism and talk about human rights and duties and obligations have no clear conceptual understanding of these notions—they lack the theological background needed to give significance to talk about rights and other moral characteristics. And in fact rights-talk often degenerates into the rhetoric of rampant individualism, attempts on the part of an individual to get her way in the midst of conflicting egos (much as the emotivists construed moral talk). For MacIntyre, our only hope is to rethink ethics and reinstate the Aristotelian conception of virtue. He recognizes that to do this we cannot appeal to the form of teleological biology that Aristotle used to ground his theory—such a metaphysical view is simply unacceptable to the contemporary mind. But if we recognize the role of practices in our lives, we will find the logical space to reintroduce talk of virtues. Our practices are co-operative forms of human activity aimed at realizing goods that can only be achieved by participating in these activities. There are family practices, political practices, economic practices, religious practices, and many others. Within such practices, the participants have roles—as husbands or wives, children or parents, citizens or politicians, workers or businessmen, church-goers or civic leaders— and these roles require certain modes of behaviour, and hence excellencies of character, in order to contribute to the attainment of the goods inherent in the practices. Without our distinctive roles, and the practices incorporating them, we would not be who we are. So in developing the virtues inherent in the roles we play in these practices, we are realizing ourselves—and helping to achieve the common good. Practices also must be understood in terms of their traditions, which link human beings with their forbears and their contemporaries, and hence with a human community within which the individual must realize herself. MacIntyre admits that all this may sound strange to contemporary readers accustomed to a different way of thinking about morality, but, as so many philosophers have done before, he suggests that we must reject the prevailing views of the day if we are at last to see the truth, in this case the truth about ethics.

This brings us to the end of a tumultuous half-century of ethical theory. The beginning of this period witnessed a radical departure from the traditional forms of ethical thought, but before the period ends we find a return to some of these very traditions. Between the beginning and end points a plethora of theories and issues have emerged. Although perhaps confusing to the novice because of the variety of positions and the shifts of focus contained in it, this period in the history of ethics is, perhaps for the very same reasons, notable for its vigour and the intellectual excitement it generates. As the end of the century approaches, ethics is alive and well, waiting for its next major controversy and its next major theory.

CHAPTER 7
Epistemology

Paul K.Moser

Epistemology is the theory of knowledge, the philosophical study of the nature, origin and scope of knowledge. During the twentieth century, accordingly, epistemologists have debated (1) what knowledge consists in (e.g. justified true belief), (2) what knowledge is based on (e.g. sensory experience) and (3) what the extent of our knowledge is (e.g. objective, conceiver-independent facts as well as subjective, conceiver-dependent facts). Debates over (1)–(3) have occupied epistemologists since the time of Plato. Twentieth-century epistemologists have not put an end to such debates, but they have made some distinctive contributions. This chapter will identify some of these contributions, giving special attention to the fundamental issue whether we have genuinely objective knowledge: knowledge of conceiver-independent facts.

EMPIRICISM REVIVED

Common sense empiricists: Moore and Russell

Twentieth-century Anglo-American epistemology begins with the rebellion of Bertrand Russell (1872–1970) and G.E.Moore (1873–1958) against Kantian and Hegelian idealism at Oxford and Cambridge. F.H. Bradley (1846–1924) and John McTaggart (1866–1925) were two leading proponents of the British idealism challenged by Russell and Moore. Russell reports:

> It was towards the end of 1898 that Moore and I rebelled against both Kant and Hegel. Moore led the way, but I followed closely in his footsteps. I think that the first published account of the new philosophy was Moore's article in *Mind* [1899] on 'The Nature of Judgement'. Although neither he nor I would now adhere to all the doctrines in this article, I, and I think he, would still agree with its negative part—i.e., with the doctrine that fact is in general independent of experience.
>
> ([7.92], 42)

Russell, following Moore, opposed any kind of idealism entailing that 'there can be nothing which is not experienced or experience' (ibid., 107). The view of Russell and Moore that 'fact is in general independent of experience [and other mental activity]' entails *realism* about facts. Realism about a fact, *F,* is just the view that *F* exists but does not depend for its existence on a conceiver's experiencing or conceiving of *F*.

Moore contrasted his realism with Kantian and Hegelian idealism as follows:

> [My] theory…differs ['from Kant's theory of perception'] chiefly in substituting for sensations, as the data of knowledge, concepts; and in refusing to regard the relations in which they stand as, in some obscure sense, the work of the mind. It rejects the attempt to explain 'the possibility of knowledge,' accepting the cognitive relation as an ultimate *datum*.… It thus renounces the supposed unity of conception guaranteed by Idealism even in the Kantian form, and still more the boasted reduction of all differences to the harmony of 'Absolute Spirit,' which marks the Hegelian development.
>
> ([7.53], 183)

Moore claimed that a 'concept is not a mental fact, nor any part of a mental fact' (ibid., 179). Concepts, he held, are the only objects of knowledge, and existing things are simply concepts or complexes thereof. Russell's talk above of facts 'independent of experience' evidently refers to Moore's non-mental concepts. (The following discussion of realism about external objects does not depend, however, on the view that objects are concepts.)

Ontological claims concern what exists. *Epistemological* claims concern what is, or can be, known—or at least justifiably believed. Russell and Moore opposed idealism not only with the ontological claim that there are mind-independent facts, but also with the epistemological claim that they *know* that there are such facts. What was the ground for the latter epistemological claim? Russell explains:

> Bradley argued that everything common sense believes in is mere appearance; we [Moore and Russell] reverted to the opposite extreme, and thought that *everything* is real that common sense, uninfluenced by philosophy or theology, supposes real. With a sense of escaping from prison, we allowed ourselves to think that grass is green, that the sun and stars would exist if no one was aware of them, and also that there is a pluralistic timeless world of Platonic ideas.
>
> ([7–89], 12)

The ground, according to Russell, is 'common sense, uninfluenced by philosophy or theology'. What exactly is common sense? Surprisingly, Russell and Moore do not say in any detail. A plausible, if rough, interpretation is that common sense for a group of people consists of beliefs common to a wide range of people within that group. Neither Russell nor Moore, however, appeals just to common sense of that sort. Neither argues, for instance, that since most people believe that God exists, we know that God exists.

Russell speaks of common sense *uninfluenced by philosophy or theology*. Why should we regard such common sense as a philosophically adequate ground for challenging idealism and supporting realism? In particular, why should we regard such common sense as a reliable source of *correct* belief regarding idealism and realism? Russell does exclude common sense influenced by philosophy or theology. This raises two issues.

First, are common sense beliefs ever altogether uninfluenced by philosophy, given a familiar broad sense of 'philosophy'? Don't common sense beliefs, in other words, typically involve broadly theoretical assumptions that are 'philosophical'? Common sense empirical beliefs about household physical objects, for example, typically rest on subjunctive conditionals: if I were to drop this mirror, it would shatter. Such conditionals are theoretical in that they go beyond simple description of what is currently present in one's perceptual experience. Russell does not say whether theoretical beliefs of that sort are 'philosophical'. It is difficult, however, to assess Russell's view without a clear statement of what he means by 'philosophy'.

Second, why should we think that common-sense beliefs uninfluenced by philosophy or theology are reliable, or are any more reliable than other common-sense beliefs? Common-sense beliefs influenced by certain kinds of sociology, psychology, politics or astronomy, for example, can be just as unreliable as

common-sense beliefs influenced by certain kinds of philosophy or theology. A widely held belief uninfluenced by philosophy or theology could still be highly unreliable owing to influence from other sources: for example, prejudicial political tactics. Perhaps, then, Russell would appeal to common-sense beliefs uninfluenced by *any* other beliefs. This would avoid the problem at hand, but only by making it questionable whether there are any common-sense beliefs of the relevant sort. It is unclear that any common-sense beliefs are influenced by *no* other beliefs. If there are such common-sense beliefs, they are very rare indeed.

In 'A Defence of Common Sense' (1925), Moore contends that 'the "Common Sense view of the world" is, in certain fundamental features, *wholly* true' ([7.54], 44). He claims, too, that he knows the relevant common sense propositions 'with certainty'. These propositions include the following:

> (a) There now exists a living human that is my body.
> (b) Before now many human bodies other than mine have lived on earth.
> (c) The earth had existed for many years before my body was born.
> (d) I have often perceived my own body and other things that form part of its environment, including other bodies.
>
> ([7.54], 33)

Moore also holds that each of us has frequently known, with respect to oneself, the propositions in question. Moore does not specify what feature common to such propositions makes them 'common-sense' propositions. He does hold, however, that we know such propositions *with certainty*.

Moore claims that the common-sense propositions in question find support from a simple consideration. If, according to certain philosophers, no such common-sense proposition is true, then 'no philosopher has ever existed, and therefore none can ever have held with regard to any such class [of common-sense propositions], that no proposition belonging to it is true' (ibid., 40). One's denial of the truth of every such common-sense proposition, according to Moore, entails that one must be wrong in denying this. In short, such a denial lands one in self-refutation.

In reply, one might make two points. First, Moore assumes that if one denies that the common-sense propositions in question are true, then one exists as a living human body. Such denial, according to Moore, requires one's actually being a living human body. What, however, supports this assumption? Conceivably, we are really disembodied thinking things who do not depend on physical substances for our intellectual lives. Descartes, in the seventeenth century, suggested this possibility in questioning presumed certainty regarding common-sense beliefs. Moore owes us evidence for his key assumption that only living human bodies could deny his common sense propositions.

Second, Moore assumes that we know his common-sense propositions *with certainty*. One can contest this assumption without denying that Moore's common-sense propositions are true. One can deny simply that we know those propositions with certainty, regardless of whether those propositions are true. Whether a proposition is true or false is one issue; whether we know that proposition with certainty, another. I can deny, for example, that I know with certainty that pandas eat peas in China. This denial does not require that I deny that it is true that pandas eat peas in China. My denial might be only a disclaimer of supporting evidence for the proposition in question. Moore owes us evidence in support of his assumption that we know his common sense propositions with certainty.

Moore did hold that he could give a proof of various commonsense propositions in question. In 1939 Moore published his 'Proof of an External World', relying on the following claims:

> I can now give a large number of different proofs [‘of the existence of things outside of us’], each of which is a perfectly rigorous proof…. I can prove now, for instance, that two human hands exist. How? By holding up my two hands, and saying, as I make a certain gesture with the right hand, ‘Here is one hand’, and adding, as I make a certain gesture with the left, ‘and here is another’.
>
> ([7.55], 145–6)

Moore claims that his ‘proof’ is ‘perfectly rigorous‘, and that it would be ‘absurd’ to suggest that he did not actually know—but merely believed—that there were two hands in the places indicated by his gestures. Such, then, is Moore’s ‘proof of the existence of external physical objects.

Moore claimed to prove, in addition, that there have been external objects in the past. Thus: ‘I held up two hands above this desk not very long ago; therefore two hands existed not very long ago; therefore at least two external objects have existed at some time in the past’ (ibid., 148). Moore insists that he does know that he held up two hands in the past, and thus that he has given a ‘perfectly conclusive proof that external objects have existed in the past’.

Moore must face an objection. His ‘proofs’ do not give us dis-proofs of either the claim that he is simply *dreaming* that he is holding up two hands or the claim that he is simply *misremembering* that he held up two hands. Moore’s reply is that he cannot prove his claim that here is one hand and there another, but that this is no real problem (ibid., 149). He finds it adequate that he has ‘conclusive evidence’ for the previous claim, and for the claim that he is not now dreaming or misremembering. We can have, on Moore’s view, conclusive evidence for, and certain knowledge of, claims we cannot prove. Moore thus claims to have conclusive evidence that he is not dreaming, even though he cannot tell us what all that evidence is.

In his 1941 paper, ‘Certainty’, Moore considers objections to his claim to certainty that he is not now dreaming. He proposes that ‘the conjunction of my memories of the immediate past with [present] sensory experiences *may* be sufficient to enable me to know that I am not dreaming’ ([7.56], 250). The objector’s reply will, of course, be that it *is* logically possible that Moore has all his present sensory experiences and memories—qualitatively characterized—but still is dreaming. Moore counters that ‘the conjunction of the proposition that I have these sense experiences and memories with the proposition that I am dreaming does seem to me to be very likely self-contradictory’ (ibid., 251). This reply, however, fails to convince. Moore gives no reason whatever to suppose it contradictory or inconceivable that he is dreaming while having his present experiences and memories. We have no reason to think that Moore cannot be dreaming while having his present experiences and memories. On the contrary, Moore’s dreaming seems perfectly compatible with those experiences and memories. Moore’s case for certainty about his common sense propositions is thus unconvincing.

One might reply that Moore’s standards for certainty and conclusiveness fit with our ordinary, non-philosophical talk of certainty and conclusiveness. Even if there is a merely logical possibility that our bodies do not exist, we typically regard ourselves as knowing with certainty—with conclusive evidence—that our bodies exist. The only *relevant* standards, on this view, are those we typically employ in ordinary, common sense talk. Since we ordinarily regard our sensory experiences of our bodies as providing conclusive evidence that we have bodies, we may claim certainty that we have bodies. Two troublesome questions arise now: How can such an appeal to ordinary standards even begin to engage familiar philosophical questions about the reliability of sensory experience? Can we plausibly ignore those philosophical questions on the ground that they are simply ‘irrelevant’? We shall return to questions about reliability in the section below on scepticism (pp. 232–41).

A key component of the common sense theories of Moore and Russell is *empiricism:* the view that the empirical evidence of the senses —e.g. visual, auditory, tactile or gustatory experiences—is a sort of

evidence appropriate to genuine knowledge. Russell's empiricism is more explicit, and perhaps more extreme, than Moore's. Russell claims:

> Nothing can be known to *exist* except by the help of experience. That is to say, if we wish to prove that something of which we have no direct experience exists, we must have among our premises the existence of one or more things of which we have direct experience. Our belief that the Emperor of China exists, for example, rests upon testimony, and testimony consists, in the last analysis of sense-data seen or heard in reading or being spoken to.
>
> ([7.84], 74–5; cf. [7.92], 97–8)

Russell here sides with such empiricists as Locke, Berkeley and Hume, against the rationalist view that *a, priori* knowledge—knowledge independent of specific experience—can provide knowledge of what actually exists. Russell sides with such rationalists as Descartes and Leibniz, however, on the point that logical principles—whether deductive or inductive—are not known on the basis of support from experience. All support from experience, Russell claims, *pre*supposes logical principles. Russell does allow, though, that our knowledge of logical principles is elicited or caused by experience. He thus permits a distinction between the *warrant* and the *cause* of a belief. In sum, Russell holds that 'all knowledge which asserts existence is empirical, and the only *a priori* knowledge concerning existence is hypothetical, giving connexions among things that exist or may exist, but not giving actual existence' ([7.84], 75). Russell's empiricism is thus moderate, allowing for some *a priori* knowledge.

Russell's talk of 'sense-data' signifies whatever in sense experience 'might be singled out by attention: particular patches of colour, particular noises, and so on' ([7.85], 142). Prior to 1918, Russell's empiricism regarded sense data as 'the epistemological basis of all our knowledge of external particulars', and as something known by 'acquaintance'. Russell ([7.83]; [7.84], chapter 5) distinguished between knowledge *by acquaintance* and knowledge *by description,* and between knowledge of things and knowledge of true propositions. Knowledge of things can be either knowledge of things by acquaintance or knowledge of things by description. Knowledge by description requires knowledge of a true proposition: knowledge *that* something is the case. Knowledge by acquaintance, in contrast, consists of direct non-propositional awareness of something, not of knowledge of truths. Russell holds that 'to say that *S* has acquaintance with *O* is essentially the same thing as to say that *O* is presented to *S*' ([7.83], 202–3). Russell would say that you are acquainted with the colour of these printed words as you read them.

After 1918 Russell abandoned sense data as the objects of cognition, and sensations as a special kind of cognition.[1] He came to reject the view that in visual colour experience, for example, there is a *subject* related via awareness to a patch of colour. Russell claimed that the subject is a 'logical fiction', much like mathematical points and instants. Having rejected the subject as an actually existing thing, Russell also rejected a distinction between sensations and sense data. The sensation of a patch of colour is, on this view, no different from the patch of colour. Such sensation thus does not qualify as a kind of knowledge. Much of Russell's epistemological work after 1918 seeks an explanation of awareness, acquaintance and empirical evidence without appeal to sense data—and often with help from John Watson's behaviourism about psychological phenomena.

Russell's epistemology, unlike Moore's, attributes definite epistemological significance to the natural sciences—a significance that gives the sciences an epistemological priority over common sense. (This is especially true of Russell's epistemological views after 1918.) Russell acknowledges that the sciences begin with common sense notions and judgements: e.g. notions of causation, space, time and things. The sciences, however, often need to revise or to eliminate such common notions to achieve their explanatory purposes.

Russell observes that we typically start our theorizing from 'naive realism', the view that things are as they seem. We initially think that the objects we perceive really are as they appear: that snow is white, that fire is hot, that feathers are soft. The natural sciences, however, provide a strikingly different view of the objects we perceive—a view entailing that the features ascribed to external objects by naive realism do not really inhere in the external objects themselves. Russell thus remarks that 'naive realism leads to physics, and physics, if true, shows that naive realism is false' ([7.88], 15).

Philosophy, according to Russell, serves an important purpose here: it identifies how fundamental common sense notions might be reconstructed to benefit the explanatory aims of the sciences. Russell denies, however, that philosophy offers a kind of knowledge ultimately different from scientific knowledge. He holds that 'philosophy involves a criticism of scientific knowledge, not from a point of view ultimately different from that of science, but from a point of view less concerned with details and more concerned with the harmony of the whole body of special sciences' ([7.87], 2).

Why, however, should we take science as our ultimate epistemological authority? This question will be especially pressing for those inclined towards scepticism about the reliability of science. Russell offers little by way of reply:

> For my part, I assume that science is broadly speaking true…. But against the thoroughgoing sceptic I can advance no argument except that I do not believe him to be sincere.
>
> ([7–91], 382)

This reply will probably convince nobody. Russell understands the *truth* of statements as their describing *facts* that may be objective in that they transcend experience ([7.90], 149, 151; [7.88], chapters 16–17). He gives no reason, however, for thinking that everyone doubtful of science's providing such truth is insincere. Epistemologists have long debated whether perception, memory, and the procedures of the natural sciences deliver objective truths. We cannot cogently settle this debate by assuming that beliefs based on perception, memory or the sciences are broadly true, and that people doubting this assumption are insincere. The use of the latter assumption aims to secure by theft what will be secured, if at all, only by extensive philosophical toil.

Let us turn now to some leading logical positivists, to see if they avoid the epistemological problems facing Moore and Russell.

Logical positivism

The science-oriented empiricism of Russell was taken to an extreme by various logical positivists, originally represented in the early 1920s by the group of philosophers, logicians, mathematicians and scientists who called themselves the Vienna Circle. Moritz Schlick (1882–1935) started the Circle at the University of Vienna, and attracted such participants as Rudolf Carnap (1891–1970), Otto Neurath (1882–1945), Herbert Feigl (1902–88), Friedrich Waismann (1896–1959), Kurt Gödel (1906–78) and Hans Hahn (1879–1934). While disagreeing on a number of substantive epistemological issues, the members of the Circle shared an interest in certain philosophical and scientific problems, and favoured an approach to these problems that was analytical, scientific and anti-metaphysical.

In 1929, Neurath, Carnap and Hahn published a manifesto for the Circle, entitled 'The Scientific Conception of the World: The Vienna Circle'.[2] They identified David Hume, the leading eighteenth-century empiricist, as one of their main philosophical forerunners. In his *Inquiry concerning Human Understanding* (1748), Hume had reached the following positivist, anti-metaphysical conclusion:

> If we take in our hand any volume, of divinity or school metaphysics, for instance, let us ask, *Does it contain any abstract reasoning concerning quantity or number*? No. *Does it contain any experimental reasoning concerning matter of fact and existence*? No. Commit it then to the flames: for it can contain nothing but sophistry and illusion.
>
> (section VII, part III).

The Vienna Circle (with the possible exception of Gödel) shared Hume's antipathy to metaphysics. They aimed to use modern logic (deriving from Frege and Russell) and various analytical techniques to restrict philosophical pursuits to the advancement of 'scientific' knowledge, thereby banishing metaphysical concerns from philosophy. Hume's extreme empiricism had questioned the meaningfulness of concepts lacking a basis in experience. The Vienna Circle, too, doubted the cognitive meaningfulness of experience-transcendent, metaphysical notions and theses.

Ludwig Wittgenstein (1889–1951) had a decisive influence on the philosophical views of the Vienna Circle. In his *Tractatus Logico-Philosophicus* (1921), Wittgenstein enunciated the following doctrines attractive to the anti-metaphysical members of the Circle:

> 4.11 The totality of true propositions is the whole of natural sciences (or the whole corpus of the natural sciences).
>
> 4.112 Philosophy aims at the logical clarification of thoughts. Philosophy is not a body of doctrine but an activity…. Philosophy does not result in 'philosophical propositions', but rather in the clarification of propositions.
>
> 6.53 The correct method in philosophy would really be the following: to say nothing except what can be said, i.e., propositions of natural science—i.e., something that has nothing to do with philosophy—and then, whenever someone else wanted to say something metaphysical, to demonstrate to him that he had failed to give a meaning to certain signs in his propositions.
>
> ([7.108])

The members of the Circle focused—typically with favour—on such anti-metaphysical theses of the *Tractatus,* rather than on its avowed mysticism: '6.522 There are, indeed, things that cannot be put into words. They *make themselves manifest.* They are what is mystical.' The Circle also welcomed Wittgenstein's view that knowledge of logical propositions is not a special kind of metaphysical knowledge about the world. Wittgenstein proposed the following: 'The propositions of logic are tautologies…. Therefore the propositions of logic say nothing. (They are the analytic propositions.)' (6.1–6.11).

The hallmark of logical positivism is a principle of verification regarding meaning and understanding—a principle not found in the *Tractatus* itself. The *Tractatus* had enunciated the following view of understanding: '4.024 To understand a proposition means to know what is the case if it is true. (One can understand it, therefore, without knowing whether it is true.)' By the late 1920s, however, Wittgenstein was endorsing a verification principle regarding meaning and understanding. In late 1929, Wittgenstein claimed:

> if I can never verify the sense of a proposition completely, then I cannot have meant anything by the proposition either. Then the proposition signifies nothing whatever. In order to determine the sense of a proposition, I should have to know a very specific procedure for when to count the proposition as verified.
>
> ([7.112], 47)

A characterization of meaning and understanding in terms of verification and justification surfaces in some of Wittgenstein's works in the late 1920s and early 1930s. In his *Philosophical Remarks* (c. 1930), Wittgenstein states that 'to understand the sense of a proposition means to know how the issue of its truth or falsity is to be decided' ([7.110], 77).[3] In his *Philosophical Grammar* (c. 1933), Wittgenstein remarks that 'it is what is regarded as the justification of an assertion that constitutes the sense of the assertion' ([7.111], I §40). In the early 1930s a number of logical positivists endorsed a principle of verification regarding meaning. Noting Wittgenstein's influence, Waismann published one of the first endorsements: 'If there is no way of telling when a proposition is true, then the proposition has no sense whatever; for the sense of a proposition is its method of verification' ([7.107], 5). We can thus put *the verification principle* succinctly: the meaning of a proposition is its method of verification.

If metaphysical claims about gods, souls, essences, values and the like lack a method of verification, we can use the verification principle to dispense with them as meaningless. The Vienna Circle did indeed dispense with them as meaningless, not just as unknowable. They construed the needed method of verification as a method of justification, or confirmation, in terms of *observable* events or situations. They thus held that every meaningful claim could be expressed in terms of observational claims: i.e. claims susceptible to confirmation or disconfirmation on the basis of observation. Schlick [7.94] specified that the meaning of a claim depends not on its actual verification, but only on the *possibility* of its verification on the basis of experience.

The members of the Circle divided over the nature of the fundamental observational claims—so-called 'protocol statements'—that set the standard for confirmation and meaningfulness.[4] One key issue was whether these observational claims are solely about what is given in subjective, private experience or can include intersubjectively testable claims about physical states of affairs. In his *The Logical Structure of the World* (1928), Carnap aimed to show in detail how all meaningful concepts could be reduced to 'the "given", i.e.,…experiences themselves in their totality and undivided unity' ([7.14], 108). In particular, Carnap sought to define a range of observationally relevant concepts (e.g. colour concepts, visual-spatial concepts) on the basis of the single fundamental concept of 'recollection of similarity' between elementary experiences. By the early 1930s, however, Carnap had moved to Neurath's view that protocol statements can be formulated in intersubjectively shared language about physical situations.

The main problems facing logical positivism concern not the conditions for protocol statements, but rather the status of the verification principle itself. One problem is that some meaningful claims seem not to admit of a 'method of verification'. Consider, for example, the claim that an omnipotent being exists: a being sufficiently powerful to accomplish anything that can be coherently described. Presumably, I understand this claim, but I have no method of confirmation or disconfirmation for it. I seemingly understand what, in general, it would be for that claim to be true or false; at least our ordinary notions of meaning and understanding allow for this. I lack, however, any means —including any observational means—of confirming or disconfirming that claim. Indeed, there seems not to be even a possible means available to me for confirming or disconfirming that claim. I lack a *method* of verification, but the claim in question still seems meaningful—at least by ordinary standards. If we weaken conditions for verification, to allow for the desired method, we shall disable the principle of verification from excluding metaphysical claims as meaningless.

What about the principle of verification itself? Does it itself admit of a method of verification resting on observational evidence? This seems doubtful. Our observational evidence, deriving from sensory and perceptual experience, fails to provide a straightforward method of verification for the verification principle itself. Perhaps, then, the verification principle is meaningless by its own standard for meaningfulness.

A.J.Ayer (1910–89), who attended meetings of the Vienna Circle by 1933, treats this self-referential difficulty as follows:

> The Vienna Circle tended to ignore this difficulty: but it seems to me fairly clear that what they were in fact doing was to adopt the verification principle as a convention. They were propounding a definition of meaning which accorded with common usage in the sense that it set out the conditions that are in fact satisfied by statements which are regarded as empirically informative. Their treatment of *a priori* statements was also intended to provide an account of the way in which statements actually function. To this extent their work was descriptive; it became prescriptive with the suggestion that only statements of these two kinds should be regarded as either true or false, and that only statements which were capable of being either true or false should be regarded as literally meaningful.
>
> ([7.9], 15)

Carnap [7.15] had also suggested that the verification principle was a 'convention' resting on a choice about how to use certain language.

The claim that an omnipotent being exists raises problems for the descriptive and the prescriptive use of the verification principle. We seemingly have no method for the possible verification of that claim; nonetheless, common usage of 'meaningful' allows us to regard that claim as meaningful. The descriptive use of the verification principle thus runs afoul of common usage of 'meaningful'. As for the prescriptive use of that principle, we need a good reason for regarding as meaningless such a claim as that an omnipotent being exists. Even if we can clearly distinguish what is empirically verifiable from what is empirically unverifiable, we need a specific reason to regard the unverifiable as the meaningless. Given our ordinary understanding of meaningfulness, the claim that an omnipotent being exists is not gibberish. That claim makes sense even if it is unverifiable. It is doubtful that we have a compelling reason to give up this ordinary approach to meaningfulness.

The role of convention in the epistemology of the Vienna Circle led to a kind of pragmatism—an emphasis on purpose-relative, practical considerations in epistemology. This is understandable because questions about which linguistic conventions to adopt are naturally understood as questions about which conventions best serve one's linguistic and theoretical purposes. Carnap identified one practical consideration as follows:

> Suppose a sentence *S* is given, some test-observations for it have been made, and *S* is confirmed by them in a certain degree. Then it is a matter of practical decision whether we will consider that degree as high enough for our acceptance of *S*.… Although our decision is based upon the observations made so far, nevertheless it is not uniquely determined by them. There is no general rule to determine our decision. Thus the acceptance and the rejection of a (synthetic) sentence always contains a *conventional component*.
>
> ([7–16], 49)

This view entails only that our decisions about rational acceptance have an ineliminable conventional component, not that they are wholly conventional.

By 1950 Carnap's pragmatism was explicit. Realists about the external world typically affirm that there really are observable spatiotemporal things and events. Subjective idealists question the reality of the thing world itself. The controversy between realists and idealists has persisted since the beginning of philosophy. Carnap gives the controversy a pragmatic spin:

> Those who raise the question of the reality of the thing world itself have perhaps in mind not a theoretical question…, but rather a practical question, a matter of practical decision concerning the structure of our language. We have to make the choice whether or not to accept and use the forms of expression in the [linguistic] framework in question.
>
> ([7.17], 207)

Carnap acknowledges that 'the thing language' efficiently serves many purposes of everyday life, and that it is advisable to accept the thing language on this pragmatic basis. He rejects, however, any suggestion that such a pragmatic basis can provide confirming evidence for 'the reality' of the thing world. A statement of the reality of the total system of certain entities (e.g. spatio-temporal things), according to Carnap (ibid., 214), is a 'pseudo-statement without cognitive content'. Questions about the total system of certain entities —what Carnap called 'external questions'—make sense, on this view, only as *practical* questions about whether to adopt certain ways of using language.

Agreeing with Carnap, Herbert Feigl emphasized the role of pragmatic considerations in epistemology. He noted that if we try to justify the rules of deductive logic in terms of *what follows from* what we mean by certain terms—e.g. 'correct reasoning', we then rely on the very rules we seek to justify. Such circularity, according to Feigl [7.31], indicates that we have reached the limits of justification. Feigl notes, however, that we can still pursue *pragmatic vindication* in such a case; for we can recommend adoption of the rules relative to achieving certain ends: e.g. avoidance of the perplexities of ambiguity and inconsistency. Regarding our familiar talk of mind-independent things, Feigl takes a similarly pragmatic approach: 'The only sort of justification we can give…consists in showing the indispensability and the adequacy of the language required for the purpose of such sciences as physics, psychology, or history' (ibid., 132–3). Such pragmatic justification involves something's serving as a means to an end, or a purpose, we have. Barring circularity, ultimate justification, on Feigl's account, is instrumental and pragmatic: relative to certain purposes an inquirer has.

By the 1950s the logical positivists of the 1920s had moved towards pragmatism in epistemology. In doing so, they were reviving themes from an American movement that antedated the Vienna Circle. We turn now to some themes from classical American pragmatism.

Classical American pragmatism

C.S.Peirce (1839–1914), the founder of American pragmatism, offered his pragmatism originally as a view about meaning: 'there is no distinction of meaning so fine as to consist in anything but a possible difference of practice' ([7.71], 30). The general idea is that for any conception we have, we can understand the meaning of that conception solely in terms of the experiential and practical effects of its object. Peirce thus suggests that if Protestants and Catholics agree about all the possible experiential effects of the object of the notion of Communion (involving wafer and diluted wine), they actually agree on the meaning of 'Communion'. This view may surprise Protestant and Catholic theologians (who take themselves to disagree), but Peirce offers it as a way to avoid both 'deception' and empty controversy from metaphysics.

We saw in the previous section that the verification principle of logical positivism conflicts with what many of us understand as meaningfulness. That principle rigidly ties meaningfulness to a method of empirical verification. Peirce's principle ties meaning instead to the possible experiential effects of the object of a notion. One problem is that some notions—e.g. mathematical, logical and certain fictional notions—lack objects with possible experiential effects, but nonetheless seem meaningful. Another problem is that the meaningfulness of some notions seems to derive simply from *what we imagine would be the case*

if that notion were realized (or, had an instance). What we imagine would then be the case, however, is not necessarily the same as *what we would (possibly) experience* as being the case. The Catholic notion of transubstantiation and the Protestant notion of Communion require (for their satisfaction) different things to *be* the case—regardless of whether we (possibly) *experience* different things as being the case. (The Catholic notion requires for its satisfaction a transformation of the bread and wine; the Protestant notion does not.) In so far as the Catholic and Protestant notions require different things for their satisfaction, we can plausibly regard those notions as meaning different things. This may leave us with some difficult, perhaps even undecidable questions about what actually exists or occurs. It seems implausible, however, to try to avoid such questions by stipulating a notion of meaning that entails their meaninglessness.

William James (1842–1910) expounded pragmatism in considerable detail, for non-philosophers as well as philosophers. He offered his pragmatic account of truth as capturing 'the meaning' of 'truth'. In a chapter of *Pragmatism* entitled 'Pragmatism's Conception of Truth', James writes:

> True ideas are those that we can assimilate, validate, corroborate, and verify…. That is the practical difference it makes to us to have true ideas; that, therefore, is the meaning of truth, for it is all that truth is known as.
>
> ([7.44], 97; cf. [7.45], 3–4)

Some philosophers have objected that James simply confuses what it is for a claim to be *true* and what it is for a claim to be *verified*.[5] These philosophers typically cite cases where a claim is true but not verifiable. Consider, for example, the status of the claim that the Earth is round before this could be verified.

James is unmoved. In disputes with critics—including those offering the view that truth does not depend on anything like verification—James invokes his 'pragmatic method':

> When a dispute arises, that [pragmatic] method consists in auguring what practical consequences would be different if one side rather than the other were true. If no difference can be thought of, the dispute is a quarrel over words. What then would the self-transcendency [of true ideas] affirmed to exist in advance of all experiential mediation or termination, be *known as*? What would it practically result in for *us,* were it true?
>
> ([7.43], 39–40)

Given this pragmatic method, James infers that a dispute over the nature of truth (e.g. whether truth is independent of verification) is an empty verbal matter if unaccompanied by a difference in practical consequences.

James ([7.45], 61–9) holds that his pragmatic method enables a non-mysterious account of what it is for a knower to have a perceptual object 'in mind'. James characterizes one's having an object in mind as one's having a certain sequence of experiences. He understands something's being a perceptual *representation* of a sensory object as that thing's being a *substitute* for that sensory object. James uses his pragmatic method to clarify what it is to be such a substitute: an idea is a substitute if it has certain 'practical consequences' relative to a knower's purposes, viz. the same practical consequences as the object for which it is a substitute. Representation, on James's account, is thus a matter of two things fulfilling the same function: sameness of practical consequences of what represents and what is represented.

It is difficult to assess James's view in the absence of a straightforward account of what count as 'practical consequences'. It helps only a little to say that a practical consequence is whatever 'makes a difference to experience'. This just shifts the task to giving a straightforward account of 'making a

difference to experience'. We saw above, in connection with Peirce's approach to meaning, that meaningfulness is not obviously fully determined by consequences for experience. James's pragmatism, like Peirce's, rests on a questionably restrictive approach to meaning.

John Dewey (1859–1952) and C.I.Lewis (1883–1965) shared the view of James that knowledge has an ineliminable pragmatic component. This pragmatic component is an element of 'active interpretation' that supposedly resides in all knowledge. In sensory, empirical knowledge, we use interpretation via concepts to organize and characterize input from sensation. The American pragmatists offered a distinctive account of when an interpretation of sensory input is 'correct.' The key idea is that an interpretation is correct to the extent that it 'usefully leads' from one experience to another, where useful leading depends on practical results relative to one's purposes in explaining and ordering one's experiences. The pragmatists' emphasis on practical results and useful leading aims to provide an alternative to an older empiricist view that the correctness of an interpretation depends on 'correspondence' to the facts of experience. James and other pragmatists faulted that older approach for failing to provide an intelligible or verifiable account of when an interpretation actually corresponds to the facts of experience.

In *The Quest for Certainty* (1929), Dewey offered an 'experimental theory of knowing' that aimed to improve on empiricism, rationalism and the influential hybrid epistemology of Immanuel Kant (1724–1804). According to Dewey, 'the method of physical inquiry is to introduce some change [in experience] in order to see what other change ensues; the correlation between these changes, when measured by a series of operations, constitutes the definite and desired object of knowledge' ([7.29], 84). Dewey 's experimental theory implies that an object of knowledge arises from controlled experimental operations, and does not exist in advance of an act of knowing. Dewey's stress on the role of control in knowledge emerges from his following remarks:

> [I]f we frame our conception of knowledge on the experimental model, we find that it is a way of operating upon and with the things of ordinary experience so that we can frame our ideas of them in terms of their interactions with one another, instead of in terms of the qualities they directly present, and that thereby our control of them, our ability to change them and direct their changes as we desire, is indefinitely increased. Knowing is itself a mode of practical action and is *the* way of interaction by which other natural interactions become subject to direction.
>
> ([7.29],106–7)

Dewey thus puts *doing* at the heart of knowing, stressing that a knower is an *active* participant in a knowing situation, and not a mere spectator. Dewey finds active participation even in connection with the so-called 'data' of sensation. He characterizes knowers as *selecting,* and not merely being *given,* such data. Dewey countenances, nonetheless, the importance of both sensation and reason in knowledge. Ideas of reason, in his view, are important for relating experiences and making predictions, and experience is important as a basis for the testing of ideas, including predictions.

Lewis concurs with Dewey's stress on the active role of knowers. Indeed, Lewis regards the distinguishing feature of pragmatism as its emphasis on a knower's act of interpretation relative to the data of sensation. Truths about experience, on Lewis's pragmatism, are always expressed by, and thus depend on, a conceptual system chosen on pragmatic grounds. Lewis explains:

> [T]he point of the pragmatic theory is…the responsiveness of truth to human bent or need, and the fact that in some sense it is made by mind…. [T]he interpretation of experience must always be in terms of categories and concepts which the mind itself determines. There may be alternative conceptual

> systems, giving rise to alternative descriptions of experience, which are equally objective and equally valid, if there be not some purely logical defect in these categorial conceptions. When this is so, choice will be determined, consciously or unconsciously, on pragmatic grounds…. [T]he pragmatic element in knowledge concerns the choice in application of conceptual modes of interpretation.
>
> ([7.49], 271–2; cf. p. 257)

Lewis holds that all interpretation includes an experience-independent, *a priori* element, and that this interpretive element receives support not from experience, but from pragmatic factors: e.g. 'some demand or purpose of the mind itself (ibid., 267).

Lewis argues that empirical knowledge consists of three elements: the immediate data of sensation, the concept or category under which those data are subsumed, and the mental act that interprets the data by means of the concept. Both Lewis and James hold that apart from an act of interpretation, one's experience would be the 'buzzing, blooming confusion of the infant'. An act of interpretation, in their view, enables such confusion to become an ordered world of experience. Lewis takes pains to defend the independence of a purely sensory, 'given' element in experience; but as a pragmatist, he stresses the pragmatic basis for the application of concepts to the data given in experience.[6] Concepts, on his view, are 'instruments of interpretation'. Lewis sums up his view thus: 'wherever such criteria as comprehensiveness and simplicity, or serviceability for the control of nature, or conformity to human bent and human ways of acting play their part in the determination of such conceptual instruments, there is a pragmatic element in knowledge' ([7.48], 211).

James, Dewey and Lewis agree, then, that knowledge requires active interpretation, and that the rationale for a particular mode of interpretation is pragmatic, deriving from one's interpretive purposes. Often we do seek a pragmatic rationale for a manner of interpretation. We then wonder about the practical consequences of wielding certain concepts (or, ways of classifying), relative to our explanatory purposes. Such a pragmatic rationale concerns the instrumental effectiveness of certain concepts in achieving our theoretical purposes, whatever those purposes happen to be.

Can there be a rationale for concepts that is not pragmatic? Has Lewis, for example, overlooked a cognitive basis for choosing concepts that is not merely pragmatic? *Perhaps* we can assess concepts relative to something more objective and less variable, viz. relative to the reliability of their portrayal of the objective, conceiver-independent world. Some philosophers hold that the latter kind of assessment, in terms of objective reliability, is distinctively 'epistemological', and that a merely pragmatic rationale can be (and often is) irrelevant to such epistemological assessment. The underlying assumption is that epistemological assessment is centrally concerned with objective, purpose-independent truth and reliable indications of such truth. Pragmatic success can sometimes get by with beliefs that are unreliable and even false—such as when it is convenient for our purposes to maintain an unreliable, false view on something.

If we can make sense of talk of objective, purpose-independent correctness, we can distinguish epistemological from pragmatic assessment. A notion of purpose-independent correctness can allow that what set of concepts we wield in theorizing often depends on our purposes in theorizing. The key issue now is, however, whether it makes sense to talk of the purpose-independent correctness of concepts. The rough idea from the critic of pragmatism is this: the external world is featured in certain mind-independent ways (e.g. many of its objects have 'natural' boundaries), and our classificatory concepts can be more or less accurate, or reliable, in how they 'fit' the mind-independent features of the external world. If we can make sense of such talk of accurate fitting, we can acknowledge a distinctively epistemological concern: do our concepts accurately fit the external world? Here we have an issue of crucial importance in epistemology.

We shall return to questions about reliability in the section below on scepticism (pp. 232–41), after considering some further developments in epistemology.

PROBLEMS FOR EMPIRICISM

Prominent twentieth-century empiricists before 1950 typically accepted an analytic-synthetic distinction: roughly, a distinction between propositions true just in virtue of meaning (or, definition) and propositions true in virtue of considerations other than meaning. Corresponding to this distinction, empiricists typically drew a distinction between empirical *(a posteriori)* knowledge and non-empirical *(a priori)* knowledge. A common view among empiricists was that all *a, priori* knowledge is knowledge of analytic truths, that there can be no *a, priori* knowledge of synthetic truths. Ayer, for example, had argued for a linguistic conception of the *a, priori* implying that the truths of logic and mathematic are *a priori* in that we cannot deny them without violating the rules governing our use of language ([7.7], chapter 4). Ayer argued that the analyticity of the truths of logic and mathematics is the only good explanation of their being knowable *a, priori,* and that we can have no *a priori* knowledge of empirical reality or of synthetic truths.

Quine on analyticity

In 1951, W.V.Quine published 'Two Dogmas of Empiricism' [7.74], challenging the following so-called dogmas of modern empiricism: belief in a dichotomy between analytic and synthetic truths, and belief in reductionism according to which every meaningful sentence is equivalent to some sentence whose terms refer to immediate sensory experience. In the aftermath of Quine's essay, philosophers have generally regarded talk of analyticity as suspect at best, and mythical at worst. A common view among epistemologists is that talk of analyticity has no genuine explanatory value in epistemology.

Quine [7.74] argues that any suitable appeal to analyticity in epistemology presupposes a notion of *cognitive synonymy* that is no more intelligible than talk of analyticity itself. One class of analytic statements —so-called *logically true* statements—does not attract this objection from Quine. Such statements, represented by 'No unmarried man is married', remain true under all reinterpretations of their non-logical components. A second class of statements, represented by 'No bachelor is married', does invite Quine's objection. Some philosophers hold that the members of the latter class reduce to logical truths by substituting synonyms for synonyms: e.g. 'unmarried man' for 'bachelor'. Other philosophers have talked instead of reducing the second class of analytic statements to the first *by definition.* They rely on the proposal that we *define* 'bachelor' as 'unmarried man'. Quine objects to such talk of definition, claiming that it typically rests on an inadequately explained notion of synonymy concerning what is defined and certain antecedent linguistic usage. The presumed notion of *synonymy,* according to Quine, needs clarification no less than does the notion of analyticity.

Quine has related objections to the view that synonymy consists in interchangeability of linguistic forms *salva veritate*—without change of truth-value. In a language free of such modal adverbs as 'necessarily', interchangeability *salva veritate* will not guarantee synonymy. It will provide only such statements as: 'All and only bachelors are unmarried men.' Proponents of synonymy hold that truths of that sort depend only on considerations of *meaning,* not on coincidental factual matters. We might, accordingly, introduce the adverb 'necessarily' to preserve a contrast between considerations of meaning and considerations of contingent matters. Quine objects, however, that such use of 'necessarily' is intelligible only if the notion of analyticity is already understandable—and it is not. We still need, then, an account of analyticity.

Quine anticipates an effort to explain analyticity via a verification theory of meaning. An analytic truth, in this view, is a statement confirmed 'no matter what', i.e. 'come what may'. Quine endorses *epistemic holism* instead: the view that statements are confirmed or disconfirmed not individually on the basis of experience, but only as a 'field'. Given Quine's holism, any statement can be accepted come what may, so long as we revise—perhaps drastically—other parts of our field of accepted statements. Holism entails also that no statement is in principle beyond revisability. Quine thus concludes that the verification approach to analyticity relies on an implausibly atomistic approach to confirmation and disconfirmation. In 'Two Dogmas,' Quine allows only for analyticity by conventional abbreviation:

> There does…remain still an extreme sort of definition which does not hark back to prior synonymies at all: namely, the explicitly conventional introduction of novel notations for purposes of sheer abbreviation…. Here we have a really transparent case of synonymy created by definition; would that all species of synonymy were as intelligible. For the rest, definition rests on synonymy rather than explaining it.
>
> ([7.74], 26)

Quine says no more about such conventional definition as a basis for analyticity. He does not consider the possibility that a philosophically important notion of analyticity emerges from such definition. Quine now contends that holism removes any epistemological need for analyticity:

> I now perceive that the philosophically important question about analyticity and the linguistic doctrine of logical truth is *not* how to explicate them; it is the question rather of their relevance to epistemology. The second dogma of empiricism, to the effect that each empirically meaningful sentence has an empirical content of its own, was cited in 'Two Dogmas' merely as encouraging false confidence in the notion of analyticity; but now I would say further that the second dogma creates a need for analyticity as a key notion of epistemology, and that the need lapses when we heed Duhem and set the second dogma aside.
>
> ([7.76], 207)

Quine's (qualified) holism about meaning implies that we do not need analyticity to account for the meaningfulness of logical and mathematical truths. Their meaningfulness can be regarded as deriving from their figuring in the natural sciences for the implication of various observationally testable statements. Logical and mathematical truths, on this view, are not divorced from empirical content; they rather participate, if indirectly, in the empirical content of various observational statements. Similarly, we do not need analyticity to explain the *necessity* of logical and mathematical truths. According to Quine: 'Holism accounts for it by freedom of selection and the maxim of minimum mutilation' ([7.78], 56). Necessity, on this view, is just a matter of our current unwillingness to dispense with certain statements at the centre of our web of belief.

In sum, Quine's objection to analyticity is twofold: first, 'for all its *a priori* reasonableness, a boundary between analytic and synthetic statements simply has not been drawn' ([7.74], 37); and second, the epistemological need for analyticity lapses once we accept holism of a certain sort. Some philosophers oppose Quine's objection on the ground that the viability of a notion of analyticity does not really depend on an account of analyticity of the sort demanded: namely, an account independent of the aforementioned notions deemed insufficiently clear by Quine. The issue here is whether Quine's standards for adequate clarity in an account of analyticity are simply too rigid. (On this matter, see Grice and Strawson [7.49].)

Carnap on analyticity

In reply to Quine, Carnap proposes that a statement is analytic if and only if it is a logical consequence of 'meaning postulates' that specify meaning relations holding among certain terms ([7.18]; [7.19], 918). (We can use stipulative definitions as a familiar kind of meaning postulates.) Quine objects that we do not gain real understanding by talking of 'meaning postulates', since we lack clear understanding of talk of 'meaning'. Quine's objection seems plausible on this point: we do need a standard of some sort to clarify talk of meaning and analyticity. Quine himself demands an empirical behavioural criterion, for this reason: 'There is nothing in linguistic meaning beyond what is to be gleaned from overt behavior in observable circumstances' ([7.78], 38).

Quine's reason will be uncompelling from the perspective of various *now*-behaviourist conceptions of meaning: conceptions allowing that meaning can arise from psychological processes or events that need not be identifiable in overt behaviour. These conceptions allow that psychological behaviour can be covert yet constitutive of meaning. Since Quine does not undercut such conceptions, he must restrict the kind of meaning he anchors in overt behaviour. His requirement that meaning be 'gleaned from overt behavior in observable circumstances' must be restricted to *socially learned,* public linguistic meaning—the kind of meaning in shared natural languages. Given that restriction, we can allow for Quine's behavioural criterion; for social linguistic meaning does depend on public behavioural evidence.

Carnap has tried to meet Quine's demand for a public behavioural criterion for analyticity. Consider a case of two linguists disagreeing over whether the following sentence is analytically true for you in your language: 'All ravens are black.' These linguists test their competing hypotheses by asking you whether you would withdraw your assertion of 'All ravens are black' if someone showed you a white raven. You could reply in either of two ways: (1) I would withdraw my assertion if presented with adequate evidence for the existence of a white raven; (2) I would not withdraw my assertion, since I do not call white birds 'ravens'; there cannot be white ravens, given my use of the term 'raven'. Carnap holds that response (2) supports the hypothesis that 'All ravens are black' is analytic for you, whereas response (1) supports the hypothesis that it is not. He concludes that ascriptions of analyticity can be tested by observation of public linguistic behaviour ([7.19], 920).

We can put Carnap's point as follows: whenever you reject all falsifiers of an assertion, by invoking only considerations about your usage of that assertion's constituent terms, we may regard that assertion as analytically true for you. This provides a behavioural criterion for analyticity, but not an infallible criterion. You might reject all falsifiers, when asked, simply because of an aim to deceive us about what is analytic for you, or simply because of confusion over what your usage of the relevant terms actually is. A rejection of all falsifiers thus does not guarantee analyticity in any familiar sense.

An improved criterion for analyticity is: a sentence, *S,* is analytically true for you if and only if you would reject all falsifiers of *S* owing just to your actual usage of S's constituents. This criterion restricts the basis of one's rejection of all falsifiers to one's actual usage of *S*'s constituent terms; it disallows rejection due to linguistic confusion or an aim to deceive. Carnap would have us understand actual usage in terms of one's 'intentions' regarding ways of using terms. He claims that theorists are 'free to choose their [meaning] postulates, guided not by their beliefs concerning facts of the world but by their intentions with respect to the meanings, i.e., the ways of use of the descriptive constants' ([7.18], 225). The analytic truths of one's linguistic system, on Carnap's view, result from intentions, or 'postulates', concerning 'the ways of use' of terms.

Carnap denies that his approach identifies analytic truths with truths that 'hold come what may' ([7.19], 921). He distinguishes two kinds of change in accepted statements: a change in the language one uses, and a change in a truth-value ascribed to a statement whose truthvalue is not fixed just by the rules of one's

language. Analytic statements, by definition, do not undergo changes of the second sort. One can change one's language, however, by adopting different meaning postulates. Some truth-values, on Carnap's view, are fixed just by the rules of language; others are not. This is a key assumption of Carnap's approach to analyticity. We must recognize the person-relativity of analyticity on Carnap's view. What is analytic, on this view, can vary from person to person, owing to variability of intentions regarding use of terms. Quine does not give adequate attention to such personrelativity of analyticity.

Let us turn now to the question whether Quine's epistemology can really make do without any notion of analyticity.

Analyticity in epistemology

An adequate epistemology relies on *epistemic principles* that specify what conditions epistemic warrant (or, justification) consists in. These principles yield an intelligible notion of warrant. Even Quine's epistemology relies on epistemic principles. One of Quine's main epistemic principles is his 'maxim of minimum mutilation': a principle of conservatism implying that it is good not to alter our antecedent theory more than necessary ([7.78], 15, 56). Quine does hold that another epistemic principle—concerning the maximization of the 'simplicity' of theory—can prevail over his principle of conservatism; but this will not affect the point to be made. We shall consider only cases where the two principles do not conflict.

The key question now is: in virtue of what is Quine's epistemic principle of conservatism true, or correct? In virtue of what is it true —or actually the case—that warranted theory revision conforms to the maxim of minimum mutilation? What, in other words, makes Quine's epistemic principle true rather than false? These questions will highlight the importance of analyticity for epistemology. They are not questions seeking a causal explanation of why certain people use Quine's epistemic principles. They rather seek an explanation why Quine's principles are true rather than false. What answer might Quine give?

One cannot answer by simply saying that the principle of conservatism requires that warranted theory revision be constrained by the principle of conservatism. It is not informative now to say that given the principle of conservatism, the principle of conservatism is true. The question above asks what *makes it the case* that *warranted* theory revision is constrained by the principle of conservatism. It is highly plausible to assume that it is just part of Quine's usage of the term 'epistemic warrant' that the principle of conservatism constrains epistemic warrant. Given this assumption, we may say that it is analytically true for Quine that the principle of conservatism constrains epistemic warrant.

Quine suggests that his epistemic principles of conservatism and simplicity find support in actual scientific practice. He claims that these principles 'are maxims by which science strives for vindication in future predictions' ([7.78], 15). This suggests the view that Quine's epistemic principles are *justified* by their role in actual scientific practice. One might propose further that Quine's principle of conservatism is *true* in virtue of its role in actual scientific practice. We can grant this proposal now, if only for the sake of argument, and then ask: In virtue of what is it true—or the case—that actual scientific practice constrains epistemically warranted theory revision? The most plausible answer is that it is just part of Quine's usage of 'epistemic warrant' that actual scientific practice constrains epistemic warrant. It is analytically true for Quine that scientific practice constrains epistemic warrant. Appeal to scientific practice thus does not free one from the importance of analyticity. Barring analyticity, we would have difficulty answering questions of the sort just raised. This may explain why Quine remains silent on such questions.

Appeals to holism take nothing away from the importance of analyticity. The epistemic holist uses the term 'epistemic warrant' in such a way that considerations of coherence determine warrant. A question of the sort just raised can thus reveal the importance of analyticity even for the epistemic holist, Quine

included. Since Carnap's aforementioned characterization of analyticity is not a characterization of justification or evidence, it is not an alternative to epistemic holism —the sort of holism Quine uses to criticize analyticity ([7.74], 41). As for *semantic* holism—holism about meaning rather than evidence, Quine's commitment is explicitly qualified, given his view that some observation statements do have their empirical content individually ([7.77], 426). Holism about warrant, in any case, does not require holism about meaning. Considerations about holism thus do not threaten the foregoing remarks about analyticity.

Quine might seek refuge in the view that we can simply forego talk of epistemic warrant and all such normative talk. This, however, would be an implausibly extreme move, a move inconsistent with Quine's own linguistic practices. Such a move would remove all evaluative talk from epistemology and philosophy in general. Instead of evaluating statements relative to epistemic standards, we could, on this view, only describe statements relative to how entrenched, or firmly held, they are. Quine himself does not settle for mere descriptions of how entrenched statements are. He is, in fact, well known for his view that 'the lack of a standard of identity for attributes and propositions can be viewed…as a case of defectiveness on the part of "attribute" and "proposition"' ([7.75], 244). Such talk of *defectiveness* is not the language of someone shunning normative, or evaluative, talk. In Two Dogmas' and elsewhere, Quine uses his views of actual scientific theory revision to set *evaluative* epistemic standards—standards involving holistic coherence, simplicity and minimum mutilation. Since Quine does have evaluative epistemic standards, he must face the questions about correctness raised above. Those questions reveal the philosophical importance of analyticity.

We should observe a distinction neglected by Quine, especially in 'Two Dogmas': the distinction between *what is true* in virtue of a certain policy of linguistic usage and *what justifies* such a policy. This is the distinction between what a policy of usage involves or entails and what supports such a policy. Confusion over this distinction apparently underlies Quine's opposition to analyticity. A statement can be analytically *true* just in virtue of a usage policy, even if that usage policy is supported, or *justified,* only by certain alterable explanatory purposes a language-user has. The alterability of the supporting purposes does not discredit the analyticity arising from a policy of usage. The category of the analytic is not the epistemic category of the *a priori;* nor does it entail unrevisability. Usage policies can and do change—often as a result of changing explanatory purposes. Change in a usage policy is a change in language. The category of the analytic characterizes a kind of *truth* resulting just from a policy of usage. It is not an epistemic category that connotes a special kind of warrant or evidence. Still, the category of analyticity can contribute to epistemology: it enables answers to the questions above about correctness of epistemic principles.

EPISTEMIC JUSTIFICATION

We noted above (p. 217) that Quine endorses epistemic holism: roughly, the view that the epistemic warrant, or justification, of a statement depends on the warrant of other statements. According to the so-called 'traditional analysis' of knowledge, suggested in Plato's *Theaetetus,* you know that *P* if and only if you have a *justified* true belief that *P*. You might believe a true groundless conjecture, but would not thereby *know* that this conjecture is true. Standardly construed, knowledge requires not only that a belief-condition and a truth-condition be satisfied, but also that the satisfaction of the belief-condition be *appropriately related* to the satisfaction of the truth-condition. The latter requirement leads to a justification-condition for knowledge, a condition that excludes such coincidental phenomena as lucky guesses.

Twentieth-century epistemologists have given special attention to the conditions for epistemic justification, the kind of justification appropriate to knowledge. They typically have allowed for justified false beliefs, and this allowance is called *fallihilism* about justification. Fallibilism allows, for example, that the Ptolemaic astronomers before Copernicus were justified in holding their geocentric model of the universe—even though it was a false model. Justification for a proposition, according to most twentieth-century epistemologists, need not logically entail the proposition justified: it need not be such that necessarily if the justifying proposition is true, then the justified proposition is true too. When justification does logically entail what it justifies, we have *deductive* justification. *Inductive* justification, in contrast, does not logically entail what it justifies; it rather is such that if the justifying proposition is true, then the justified proposition is, to some extent, *probably* true. Twentieth-century epistemologists do not share a single account of the sort of probability appropriate to inductive justification. Most recent epistemologists do agree, however, that epistemic justification is *defeasible,* that a justifying proposition can cease to be justifying for a person when that person acquires additional justification. For instance, your justification for thinking that there is a pool of water on the road ahead can be overridden by new evidence acquired upon approaching the relevant spot on the road.

A major topic of controversy in twentieth-century epistemology concerns the kind of justification we have for our beliefs about the external world, including the belief that conceiver-independent physical objects exist. Most twentieth-century epistemologists agree that such beliefs are justified only inductively, in terms of justification that does not logically entail the beliefs justified. Some sceptics, doubting that we have epistemic justification for the belief that external objects exist, have required deductive support for that belief; others have questioned whether we can even have inductive, probabilistic justification here (see below, pp. 232–41).

Some sceptics have used a *regress argument* to contend that we are not justified in believing anything about the external, conceiver-independent world (cf. Oakley [7.69]). This argument stems from the question whether, and if so how, we are justified in holding any belief about the external world on the basis of other beliefs, i.e. on the basis of so-called *inferential* justification. A sceptic's use of the regress argument aims to show that each of the available accounts of inferential justification fails, and thus that such justification is not to be had. The initial sceptical worry is: if one's belief that external objects exist is supposedly justified on the basis of another belief, how is the latter, allegedly justifying belief itself justified? Is it supposedly justified by a further belief? If so, how is the latter belief itself justified? We seem to be threatened by an endless regress of required justifying beliefs—a regress that seems too complex to employ in our actual everyday reasoning. Our options, according to many epistemologists, are straightforward: (1) explain how an endless regress of required justifying beliefs is not actually troublesome, or (2) show how we can terminate the threatening regress or (3) accept the sceptical conclusion that inferential justification is impossible.

A concrete example illustrates the problem of inferential justification. While walking along Lake Michigan, we decide that a swim today would be pleasant, but that the current dangers of swimming outdoors are too great. Our belief that swimming outdoors is dangerous today is supported by other beliefs we have. We believe, for example, that (1) local meteorologists have predicted lightning storms today in our area, (2) there are foreboding cumulonimbus clouds overhead and (3) the meteorologists' reports and the presence of the cumulonimbus clouds are reliable indicators of impending lightning. Our belief that swimming outdoors is dangerous today receives support from our belief that (1), (2) and (3) are true. What, however, supports (1), (2) and (3) for us? Other beliefs we have will naturally contribute support here, and thus the chain of inferential justification will continue. Part of our support for (1) might be our belief that (4) we heard radio reports today from some local meteorologists; and part of our support for (2) might be

our belief that (5) we see dark thunderclouds overhead. Our support for (4) and (5) might be similarly inferential, thus extending the chain of inferential justification even further.

Non-sceptical epistemologists have offered four noteworthy replies to the regress problem concerning inferential justification. The first reply, which we may call *epistemic infinitism,* proposes that regresses of inferential justification are indeed infinite, but that this consideration does not preclude genuine justification. Our belief that swimming outdoors is dangerous today, on this reply, would be justified by belief (1) above, belief (1) would be justified by belief (4) above, belief (4) would be justified by a further belief, and so on endlessly. Such infinitism, while attracting very few proponents, was supported by Charles Peirce ([7.70], 36–8), the founder of American pragmatism. Infinitism evidently requires that one must have an infinity of justifying beliefs to have an inferentially justified belief.

Sceptics will argue that infinite chains of supposedly inferential justification cannot provide genuine justification. They will note that no matter how far back we go in an infinite regress of inferential justification, we find only beliefs that are *conditionally* justified: justified *if,* and *only if,* their supporting beliefs are justified. The problem is that the supporting beliefs themselves are at most conditionally justified too: justified if, and only if, *their* supporting beliefs are justified. At every point in the never-ending chain we find a belief that is merely conditionally justified, and not actually justified. Another problem is that one's having an infinity of supporting beliefs seemingly requires an infinite amount of time, on the assumption that belief-formation for each of the supporting beliefs takes a certain amount of time. We humans, of course, do not have an infinite amount of time, and thus it is doubtful that our actual justification includes infinite regresses of justifying beliefs. Even if these considerations are not decisive, they indicate that the proponent of infinitism has some important explaining to do.

A second non-sceptical reply to the regress problem is *epistemic coherentism:* the view that all justification is inferential and systematic in virtue of 'coherence relations' among beliefs. Justification for any belief, according to epistemic coherentism, terminates in a system or network of beliefs with which the justified belief coheres. This view denies that justification is linear in the manner suggested by infinitism. We should not confuse a coherence theory of *justification*—epistemic coherentism—with a coherence theory of *truth.* A coherence theory of truth, of the sort endorsed by Brand Blanshard ([7.11], 268; [7.12], 590), aims to specify the meaning of 'truth', or the essential nature of truth; a coherence theory of justification aims to explain the nature not of truth, but of the kind of justification appropriate to knowledge. Recent proponents of epistemic coherentism, of one version or another, include: Wilfrid Sellars ([7.95]; [7.96]; [7.97]), Nicholas Rescher ([7.79]; [7.80]), Gilbert Harman ([7.40]; [7.41]), Keith Lehrer ([7.46]; [7.47]) and Laurence BonJour ([7.13]).

Proponents of epistemic coherentism have tried to answer two pressing questions: first, what kind of coherence relation is crucial to justified belief? Second, what kind of belief-system must a justified belief cohere with? Regarding the first question, many proponents of epistemic coherentism acknowledge logical entailment and explanation as coherence relations among beliefs. Explanatory coherence relations obtain when some of one's beliefs effectively explain why some other of one's beliefs are true. For example, my belief that it is raining outside might effectively explain the truth of my belief that my office windows are wet. Regarding the second question, not just any belief-system will serve the purpose of epistemic coherentism. Some belief-systems, such as those consisting of science-fiction propositions, seem obviously erroneous, and thus seem unable to provide a basis for epistemically justified belief. However one answers the previous two questions, epistemic coherentism implies that the justification of any belief depends on that belief's coherence relations to other beliefs. Such coherentism is thus systematic, stressing the role of interconnectedness of beliefs in epistemic justification.

Sceptics will ask why we should regard coherence among one's beliefs as a reliable indication of empirical truth, of how things actually are in the empirical world. (See the section below on scepticism, pp. 232–41, for more on this matter.) Consider, in addition, the following so-called *isolation objection* to epistemic coherentism: epistemic coherentism entails that one can be epistemically justified in accepting a contingent empirical proposition that is incompatible with, or at least improbable given, one's total empirical evidence (Moser [7.59], 84–103; [7.61]; [7.62], 176–82). A proponent of this objection does not restrict empirical evidence to empirical propositions believed or accepted by a person.

The isolation objection becomes universally applicable to coherence theories of justification once we expand the scope of empirical evidence beyond the propositions (or, judgements) believed or accepted by a person. Suppose, for example, that one's empirical evidence includes the subjective non-propositional contents (e.g. visual images) of one's non-belief perceptual and sensory awareness states, such as one's seeming to perceive something or one's feeling a pain. If there are such contents, then they, being non-propositional, are not among what one believes or accepts. One might, of course, accept that one is having a particular visual image, but this does not mean that the image itself is a proposition one accepts. If we include the non-propositional contents of non-belief perceptual and sensory states in one's empirical evidence, the isolation objection will bear directly on coherence theories of justification. Coherence theories, by definition, make epistemic justification depend just on coherence relations among propositions one believes or accepts. They thus neglect, as a matter of principle, the evidential significance of the non-propositional contents of non-belief perceptual and sensory states. Proponents of epistemic coherentism have not yet achieved a uniform resolution of the problem raised by the isolation objection.

A third non-sceptical reply to the regress problem is *epistemic foundationalism.* Put generally, foundationalism about epistemic justification states that such justification has a two-tier structure: some instances of justification are non-inferential, or foundational; and all other instances of justification are inferential, or non-foundational, in that they derive ultimately from foundational justification. This structural view was proposed in Aristotle's *Posterior Analytics* (as a view about knowledge), received an extreme formulation in Descartes's *Meditations* and is represented, in one form or another, in the twentieth-century epistemological works of Bertrand Russell [7.88], C.I.Lewis [7.49]; [7.50], and Roderick Chisholm [7.22]; [7.23]; [7.25], among many others.[7]

Versions of foundationalism about justification differ on two matters: the explanation of non-inferential, foundational justification, and the explanation of how justification can be transmitted from foundational beliefs to non-foundational beliefs. Some philosophers, following Descartes, have assumed that foundational beliefs must be *certain* (e.g. indubitable or infallible). Such an assumption underlies *radical* foundationalism, a view requiring not only that foundational beliefs be certain, but also that such beliefs guarantee the certainty of the non-foundational beliefs they support. Two considerations explain why radical foundationalism attracts very few epistemologists. First, very few, if any, of our perceptual beliefs are certain;[8] and, second, the beliefs that might be candidates for certainty (e.g. the belief that I am thinking) are insufficiently informative to guarantee the certainty of our highly specific inferential beliefs concerning the external world (e.g. beliefs about physics, chemistry and biology).

Most contemporary foundationalists accept *modest* foundationalism, the view that foundational beliefs need not possess or provide certainty, and need not deductively support justified non-foundational beliefs. Foundationalists typically characterize a *non-inferentially justified, foundational* belief as a belief whose epistemic *justification* does not derive from other beliefs; but they leave open whether the *causal* basis of foundational beliefs includes other beliefs. Further, they typically hold that foundationalism is an account of a belief's (or a proposition's) *having* justification for a person, not of one's *showing* that a belief has justification or is true.

Modest foundationalists can choose from three influential approaches to non-inferential, foundational justification: (1) self-justification, (2) justification by non-belief, non-propositional experiences and (3) justification by a reliable non-belief origin of a belief. Recent proponents of self-justification have included Roderick Chisholm [7.22] and C.J.Ducasse [7.30]. They contend that a foundational belief can justify itself, apart from any evidential support from something else. In contrast, proponents of foundational justification by non-belief experiences shun literal self-justification. They hold, following C.I.Lewis ([7.49]; [7.50]), that foundational perceptual beliefs can be justified by non-belief sensory or perceptual experiences (e.g. my non-belief experience involving seeming to see a keyboard) that either make true, are best explained by or otherwise support those foundational beliefs (e.g. the belief that there is, or at least appears to be, a keyboard here). Proponents of foundational justification by reliable origins hold that non-inferential justification depends on non-belief belief-forming processes (e.g. perception, memory, introspection) that are truth-conducive to some extent, in virtue of tending to produce true rather than false beliefs. The latter view invokes the reliability of a belief's non-belief origin,[9] whereas the previous view invokes the particular sensory or perceptual experiences that underlie a foundational belief. Despite the disagreement here, proponents of modest foundationalism typically agree that non-inferential justification, at least in most cases, can be defeated upon expansion of one's justified beliefs. The justification for your belief that there is a red flower in the vase, for example, might be overridden by the introduction of new evidence that there is a red light shining on the flower.

Wilfrid Sellars [7.96] and Laurence BonJour [7.13] have offered an influential argument against claims to non-inferential justification. They contend that one cannot be non-inferentially epistemically justified in holding any beliefs, since one is epistemically justified in holding a belief only if one has good reason to think that the belief is true. This, they claim, entails that the justification of an alleged foundational belief will actually depend on an argument of the following form:

(1) My foundational belief that *P* has feature *F*.
(2) Beliefs having feature *F* are likely to be true.
(3) Hence, my foundational belief that *P* is likely to be true.

If the justification of one's foundational beliefs depends on such an argument, those beliefs will not be foundational after all; for their justification will then depend on the justification of further beliefs: the beliefs represented by the premises of the argument (1)–(3).

It seems too demanding to hold that the justification of one's belief that *P* requires one's being *justified in believing* premises (1) and (2). Given that requirement, you will be justified in believing that *P* only if you are justified in believing that your belief that *P* has feature *F*. Further, given those requirements, you will be justified in believing that (1) your belief that *P* has *F* only if you are justified in believing an additional proposition: that (2) your belief that (1) has *F*. Given the requirements in question, we have no non-arbitrary way to avoid the troublesome implication that similar requirements apply not only to this latter proposition —viz. (2)—but also to each of the ensuing infinity of required justified beliefs. The problem is that we seem not to have the required infinity of increasingly complex justified beliefs.

An apparent lesson here is that if justificational support for a belief must be accessible to the believer, that accessibility should not itself be regarded as requiring further justified belief. Current debates over *internalism* and *externalism* regarding epistemic justification concern what sort of access, if any, one must have to the support for one's justified beliefs. Internalism incorporates an accessibility requirement, of some sort, on what provides justification, whereas externalism does not. Debates over internalism and externalism are currently unresolved in contemporary epistemology.[10]

Foundationalists must explain not only the conditions for non-inferential justification, but also how justification transmits from foundational beliefs to inferentially justified, non-foundational beliefs. Modest foundationalists, unlike radical foundationalists, allow for non-deductive, merely probabilistic connections that transfer justification. They have not, however, reached agreement on the exact nature of such connections. Some modest foundationalists hold that some kind of 'inference to a best explanation' can account for transmission of justification in many cases. For example, the belief that there is a computer before me can, in certain circumstances, provide a best explanation of various foundational beliefs about my perceptual inputs. This, however, is a controversial matter among epistemologists.

A special problem troubles versions of foundationalism that restrict non-inferential justification to subjective beliefs about what one *seems* to see, hear, feel, smell and taste. Those versions must explain how such subjective beliefs can provide justification for beliefs about conceiver-independent physical objects. Clearly, such subjective beliefs do not logically entail beliefs about physical objects. Since extensive hallucination is always possible, it is always possible that one's subjective beliefs are true while the relevant beliefs about physical objects are false. This consideration challenges foundationalists endorsing *linguistic phenomenalism,* the view that statements about physical objects can be translated without loss of meaning into logically equivalent statements solely about subjective states characterized by subjective beliefs.[11] Perhaps a foundationalist, following Chisholm [7.23] and Cornman [7.27], can invoke a set of non-deductive relations to explain how subjective beliefs can justify beliefs about physical objects. This remains, however, as a challenge, since no set of such relations has attracted widespread acceptance from foundationalists. We should note, though, that some versions of foundationalism allow for the non-inferential justification of beliefs about physical objects, and thus avoid the problem at hand.

A fourth non-sceptical reply to the regress problem is *epistemic contextualism,* a view suggested by Wittgenstein [7.109] and formulated explicitly by Annis [7.3]. Wittgenstein set forth a central tenet of contextualism with his claim that 'at the foundation of well-founded belief lies belief that is not founded' [7.109], §253). If we construe Wittgenstein's claim as stating that at the foundation of justified beliefs lie beliefs that are unjustified, we have an alternative to infinitism, coherentism and foundationalism.[12] In any context of inquiry, according to contextualism, people simply assume (the acceptability of) some propositions as starting points for inquiry; and these 'contextually basic' propositions, while themselves lacking evidential support, can support other propositions. Contextualists emphasize that contextually basic propositions can vary from social group to social group, and from context to context—e.g. from theological inquiry to physical inquiry. Thus, what functions as an unjustified justifier in one context need not in another.

The main problem for contextualism comes from the view that unjustified beliefs can provide epistemic justification for other beliefs. If we grant that view, we need to avoid the implausible view that *any* unjustified belief, however obviously false or contradictory, can provide justification in certain contexts. If any unjustified proposition can serve as a justifier, we shall, it seems, be able to justify anything we want. Even if we do typically take certain things for granted in certain contexts of discussion, this does not support the view that there are unjustified justifiers. Perhaps the things typically taken for granted are actually supportable by good reasons; and if they are not, we need some way to distinguish them from unjustified beliefs that cannot transmit justification to other beliefs. The contextualist must explain, then, how an unjustified belief—but not just any unjustified belief — can provide inferential justification for other beliefs. Contextualists have not reached agreement on the needed explanation.

In sum, then, the regress problem for inferential justification has a troublesome resilience about it. Infinitism, coherentism, foundationalism or contextualism may provide a viable solution to the problem, but only after a resolution of the problems noted above. Let us turn briefly now to some complications facing the analysis of knowledge.

CONDITIONS FOR KNOWLEDGE

Some recent epistemologists have proposed that we give up the traditional justification-condition for knowledge. They recommend, following Alvin Goldman [7.37], that we construe the justificationcondition as a *causal* condition. Roughly, the idea is that you know that *P* if (1) you believe that *P,* (2) *P* is true and (3) your believing that *P* is causally produced and sustained by the fact that makes *P* true. This is the basis of a *causal theory of knowing,* a theory that admits of various manifestations.

A causal theory of knowing faces apparently serious problems from knowledge of universal propositions. Perhaps we know, for instance, that all computers are produced by humans; but our believing that this is so seems not to be causally supported by the fact that all computers are humanly produced. It is not clear that the latter fact causally produces *any* beliefs. At a minimum, we need an explanation of how a causal theory can account for knowledge of such universal propositions.

The analysis of knowledge as justified true belief, however elaborated, faces a challenge that initially gave rise to causal theories of knowledge: *the Gettier problem.* In 1963 Edmund Gettier published an influential challenge to the view that if you have a justified true belief that *P,* then you know that *P.* Here is one of Gettier's [7.35] counterexamples to this view: Smith is justified in believing the false proposition that (i) Jones owns a Ford. On the basis of (i), Smith infers, and thus is justified in believing, that (ii) either Jones owns a Ford or Brown is in Barcelona. As it happens, Brown is in Barcelona, and so (ii) is true. Thus, although Smith is justified in believing the true proposition (ii), Smith does not know (ii).

Gettier-style counter-examples are cases where a person has justified true belief that *P* but lacks knowledge that *P.* The Gettier problem is the problem of finding a modification of, or an alternative to, the standard, justified-true-belief analysis that avoids difficulties from Gettier-style counter-examples. The controversy over the Gettier problem is highly complex and still unsettled. Many epistemologists take the lesson of Gettier-style counter-examples to be that prepositional knowledge requires a *fourth* condition, beyond the justification-, truth- and belief-conditions. No specific fourth condition has received overwhelming acceptance by epistemologists, but some proposals have become prominent. The so-called 'defeasibility condition', for example, requires that the justification appropriate to knowledge be 'undefeated' in the general sense that some appropriate subjunctive conditional concerning defeaters of justification be true of that justification. For instance, one simple defeasibility fourth condition requires of Smith's knowing that *P* that there be no true proposition, *Q,* such that if *Q* became justified for Smith, *P* would no longer be justified for Smith. So if Smith knows, on the basis of his visual perception, that Bubba removed books from the library, then Smith's coming to believe the true proposition that Bubba's identical twin removed books from the library would not undermine the justification for Smith's belief concerning Bubba himself. A different approach shuns subjunctive conditionals of that sort, and claims that propositional knowledge requires justified true belief that is sustained by the collective totality of actual truths. This approach requires a detailed account of when justification is undermined and restored.[13]

The Gettier problem, according to many epistemologists, is epistemologically important. One branch of epistemology seeks a precise understanding of the nature—i.e. the essential components—of propositional knowledge. Our having a precise understanding of propositional knowledge requires our having a Gettier-proof analysis of such knowledge. Epistemologists thus need a defensible solution to the Gettier problem, however complex that solution is. This conclusion is compatible with the view that various epistemologists employ different notions of knowledge at any level of specificity.

SCEPTICISM

Epistemologists have long debated the limits, or scope, of knowledge. The more restricted we take the scope of knowledge to be, the more sceptical we are. Two influential types of scepticism are *knowledge-scepticism* and *justification-scepticism.* Unrestricted knowledge-scepticism implies that no one knows anything. Unrestricted justificationscepticism implies the more extreme view that no one is even justified in believing anything. Some forms of scepticism are stronger than others. Knowledge-scepticism in its strongest form implies that it is *impossible* for anyone to know anything. A weaker form would deny the *actuality* of our having knowledge, but leave open its possibility. Many sceptics have restricted their scepticism to a particular domain of supposed knowledge: e.g. knowledge of the external world, knowledge of other minds, knowledge of the past or the future or knowledge of unperceived items. Limited scepticism is more common than unrestricted scepticism in the history of epistemology.

Arguments supporting scepticism come in many forms. One of the most difficult is *the problem of the criterion,* a version of which comes from the sixteenth-century sceptic Michel de Montaigne:

> To adjudicate [between the true and the false] among the appearances of things, we need to have a distinguishing method; to validate this method, we need to have a justifying argument; but to validate this justifying argument, we need the very method at issue. And there we are, going round on the wheel.[14]

This line of sceptical argument originated in ancient Greece, with epistemology itself. (See Sextus Empiricus, *Outlines of Pyrrhonism,* Book II.)[15] It forces us to face this question: how can we specify *what* we know without having specified *how* we know, and how can we specify *how* we know without having specified *what* we know? Is there any reasonable way out of this threatening circle? This is one of the most difficult epistemological problems, and a cogent epistemology must provide a defensible solution to it. Contemporary epistemology still lacks a widely accepted reply to this urgent problem. One influential reply from Roderick Chisholm [7.24] rules out scepticism from the start, with the assumption that we do know some specific propositions about the external world. Chisholm endorses a *particularist re*ply that begins with an answer to the question of what we know. Such a reply seems, however, to beg a key question against the sceptic. A *methodist* reply to the problem of the criterion begins with an answer to the question of how we know. Such a reply risks divorcing knowledge from our considered judgements about particular cases of knowledge. It also must avoid begging key questions raised by sceptics.

Let us consider another sceptical argument (developed in detail in Moser ([7.63] and [7.64]). Suppose that you are a realist claiming knowledge that external, mind-independent objects exist, and that you take such knowledge to entail that it is objectively the case that external objects exist. Suppose also that you regard yourself as having a cogently sound argument for your claim to knowledge that external objects exist.

> Your argument, let us suppose, takes the following general form:
>
> 1 If one's belief that *P* has feature *F,* then one knows that *P.*
> 2 My belief that external objects exist has *F.*
> 3 Hence, I know that external objects exist.

Even critics of realism may grant premise (1)—if only for the sake of argument. That premise may be just a straightforward implication of what a realist *means* by 'knows that *P*'.

Feature *F* can incorporate any of a number of familiar well-foundedness properties: (a) suitable doxastic coherence (cf. Lehrer [7.47], chapter 7), (b) maximal explanatory efficacy (cf. Lycan [7.51], chapter 7), (c) undefeated self-evidentness (cf. Foley [7.33], chapter 2), (d) consistent predictive success (cf. Almeder [7.1], chapter 4), (e) uncontested communal acceptance (cf. Annis [7.3]), (f) causal sustenance by such a belief-forming process as perception, memory, introspection, or testimony (cf. Goldman [7.38], chapter 5), (g) adequate theoretical elegance in terms of such virtuous characteristics as simplicity and comprehensiveness (cf. Thagard [7.105], chapter 5), (h) survival value in the evolutionary scheme of things (cf. Carruthers [7.20], chapter 12), or (i) some combination of (a)–(h) (cf. Cornman [7.27]). Such well-foundedness properties cannot conceptually exhaust *F;* for by hypothesis one's knowing that *P* (unlike those well-foundedness properties) *entails* its objectively being the case that *P*.

If knowledge involves more than objectively true belief, as it does on standard conceptions since the time of Plato's *Theaetetus* (cf. 202b), then *F* will be a complex property—involving the property of being objectively true plus some additional property. The additional property, on standard conceptions of knowledge, incorporates a well-foundedness feature of some sort (and sometimes a no-defeaters restriction on that feature to handle the aforementioned Gettier problem). Let us call this *the well-foundedness component of F.* A well-foundedness feature serves typically to distinguish knowledge from true belief due simply to such coincidental phenomena as lucky guesses. In this respect, such a feature may be regarded as making a belief 'likely to be true' to some extent. As suggested in the section above on epistemic justification (pp. 228– 9), an *internalist* well-foundedness feature is accessible—directly or indirectly—to the knower for whom it yields likelihood of truth; an *externalist* well-foundedness feature is not. (Cf. Alston [7.2], chapters 8, 9.)

If, as standardly assumed, knowledge that *P* entails that it is objectively the case—or objectively true—that P, the relevant kind of likelihood of *truth* must entail likelihood of what is objectively true, or objectively the case. So, whether internalist or externalist, a well-foundedness feature must yield likelihood of what is objectively the case. It must, in other words, indicate with some degree of likelihood what is the case conceiver-independently. A well-foundedness component of *F* violating this requirement will fail to distinguish knowledge from true belief due simply to such coincidental phenomena as lucky guesses.

Premise (2) generates a problem motivating scepticism about realism concerning external objects. It affirms (a) that your belief that external objects exist is objectively true, and (if you hold that knowledge has a well-foundedness component) (b) that a well-foundedness feature indicates with some degree of likelihood that external objects exist. A sceptic can plausibly raise this question:

> *Q1.* What non-question-begging reason, if any, have we to affirm that your belief that external objects exist is objectively true?

If you are a typical realist, committed to a well-foundedness component of knowledge, you will appeal to your preferred well-foundedness component of *F* to try to answer *Q1*. In particular, you will answer that the satisfaction of the conditions for that well-foundedness component provides the needed reason to affirm that your belief is true. This answer to *Q1* is not surprising, given the aforementioned assumption that a well-foundedness component yields likelihood of truth.

For any well-foundedness component a realist offers, a sceptic can raise the following challenge:

> *Q2.* What non-question-begging reason, if any, have we to affirm that the satisfaction of the conditions for *that* well-foundedness component of *F* is actually indicative, to any extent, of what is objectively the case?

Realists might reply that it is true in virtue of what they *mean* by 'indicative of what is objectively the case' that their preferred well-foundedness component is indicative of what is objectively the case. (Cf. Pollock [7.73], chapter 5.) This move uses definitional (or, conceptual) fiat to try to disarm sceptics, but actually fails to answer their main concern.

We can put the main concern more exactly:

> *Q3*. What non-question-begging reason, if any, have we to affirm that the satisfaction of the conditions for a preferred well-foundedness component of *F*—including the satisfaction of conditions definitive of what a realist means by 'indicative of what is objectively the case'—is ever a genuinely reliable means of representational access to what is objectively the case?

Equivalently, what non-question-begging reason, if any, have we to affirm that some claim satisfying the conditions for a preferred well-foundedness component (e.g. the claim that external objects exist) is actually objectively true? We can grant realists their preferred definition of 'indicative of what is the case', but then follow up with *Q3*. A sceptic may begin with *Q1,* but will move to *Q3* once a realist appeals to a well-foundedness component of *F*. It would be a shallow sceptic indeed who failed to regard *Q3* as just as troublesome for realism as *Q1* is.

Clearly, your invoking your preferred well-foundedness component to defend realism against *Q3* would be question-begging. The reliability of your preferred well-foundedness component is precisely what is under question now; and begging this question offers no cogent support for realism. If, for instance, you hold that coherent belief is indicative of objective truth, you cannot now simply presume that coherent belief is indicative of objective truth; the issue now is whether coherent belief (or any similar well-foundedness component) is actually indicative of objective truth. Perhaps *given* your preferred well-foundedness component, that well-foundedness component is itself well-founded. This consideration, however, does nothing to answer *Q3*. *Q3* asks what *non-question-begging r*eason, if any, we have to regard your preferred well-foundedness component as ever being a reliable means to objective truth. In effect: *apart from* appeal to (the reliability of) your preferred well-foundedness component, what reason have we to regard that component as ever being a reliable means to objective truth—e.g. objective truth regarding your belief that external objects exist?

A sceptic's use of *Q3* allows for fallibilism about well-foundedness: the view that a well-founded belief can be false. In addition, a sceptic's use of *Q3* need not assume that evidence on which a claim is well-founded must logically entail (or, deductively support) that claim; nor does it require that we take a controversial stand on purely conceptual disputes over the exact conditions for epistemic justification. These are some virtues of a sceptic's use of *Q3* to challenge realism.

Suppose then that you are a realist wielding argument (1)–(3), along with the standard view that *F* has a well-foundedness component (say, coherent belief). You will then hold that your belief that external objects exist illustrates a case where a belief's meeting the conditions for your preferred well-foundedness component (such as coherent belief) is an objectively true belief. You will then hold, given premise (2), that your belief that external objects exist is objectively true, and that your preferred well-foundedness component of *F* (namely, coherent belief) is satisfied by an objectively true belief in this case. You will, however, still owe the sceptic a non-question-begging reason for thinking that your preferred well-foundedness component of *F* (namely, coherent belief) is, in this case, a genuinely reliable means to objectively true belief.

Realists might aim to silence the sceptic by claiming, following Pollock [7.73], that our concept of an external object is actually constituted, or wholly determined, by certain well-foundedness conditions

involving one or more of the well-foundedness properties noted above. The claim here is that certain conditions for well-founded ascription of our concept of an external object *fully* determine that concept. This claim entails a kind of verificationism about our notion of an external object, and is not equivalent to the previous view that appealed to considerations of meaning regarding 'indication of what is objectively true'.

It seems, in reply, that our notion of an external object logically outstrips various standard well-foundedness conditions for that notion. Our concept of an external object seemingly involves, for instance, the condition that any object falling under it does not perish whenever one looks away from it, but would exist even when unperceived. The condition that an external object would exist even when unperceived seems not to be logically entailed by various standard well-foundedness conditions for our notion of an external object. For example, maximally effective explanation of (the origin of) our common perceptual experiences does not *logically* require that there be objects that exist when unperceived. Further, even if well-foundedness conditions fully determined our notion of an external object, it would still be an open question whether one's having our notion of an external object involves one's *actually satisfying* those well-foundedness conditions with one's belief that external objects exist. If those conditions entail the subjunctive condition just noted, a sceptic will demand a non-question-begging reason to think it is ever actually satisfied; and then the now familiar worries motivating scepticism will resurface. Realists, in any case, are not typically verificationists about our notion of an external object.

We may return, then, to the sceptic's main challenge, in *Q3,* for the realist to deliver a non-question-begging reason. Such a reason will not simply *presume* a realism-favouring answer to a sceptic's familiar questions about reliability. Some of these familiar questions concern the reliability, in any actual case, of our belief-forming processes (e.g. perception, introspection, judgement, memory, testimony) that sometimes produce belief in the existence of external objects. Some other familiar questions concern the reliability, in any actual case, of suitably coherent, explanatorily efficacious, or predictively successful belief regarding the existence of external objects. Each of the well-foundedness properties noted above will attract such a question about reliability from a sceptic. A sceptic will thus be unmoved by observations concerning the simplicity and comprehensiveness provided by realism about external objects. The application of *Q3* will ask for a nonquestion-begging reason to affirm that the simplicity and comprehensiveness provided by such realism is ever a reliable means to objectively true belief. Any higher-order use of a well-foundedness component — to support a well-foundedness component—meets the same fate as first-order use; for *Q3* applies equally to any higher-order use. Lacking answers to the sceptic's questions, we cannot cogently infer that realism about external objects has been substantiated.

A sceptic is not guilty of this empty challenge: give me a cogent argument, but do not use any premises. The challenge is rather: give me a cogent, non-question-begging reason to hold that your belief that external objects exist is a case where a belief satisfying your preferred well-foundedness component is an objectively true belief. The demand is not that realists forego the use of premises; it rather is just that the realist forego the use of *question-begging* premises—premises that beg relevant questions about reliability motivating scepticism. *Q1–Q3* illustrate some standard sceptical questions. A question-begging argument from a realist will not even begin to approach cogency for a sceptic. Mere soundness of argument, then, is not at issue; *cogent* nonquestion-begging soundness is.

One familiar consideration—perhaps employed only for the sake of argument by a sceptic—indicates that a sceptic wielding Q3 will *not* be successfully answered by a realist. Cognitively relevant access to *anything* by us humans depends on such belief-forming processes as perception, introspection, judgement, memory, testimony, intuition and common sense. Such processes are subject to question via Q3, and cannot themselves deliver non-question-begging support for their own reliability. Put bluntly, we cannot assume a

position independent of our own cognitively relevant processes to deliver a non-question-begging indication of the reliability of those processes. This, for better or worse, seems to be the human cognitive predicament; and no realist has yet shown how we can escape it. This, too, is a straightforward consideration favouring the conclusion that we must take scepticism quite seriously. Until we have the needed non-question-begging reason, scepticism seems more defensible, epistemically, than realism. Our inability to provide the needed non-question-begging reason does nothing to undercut the sceptic's challenge; it rather undercuts claims to cogent support for realism.

A non-question-begging reason favouring realism would be a reason that provides *effective* discernment of conceiver-independent truth. We cannot, it seems, effectively rely on *our* eyesight, for example, to test the objective reliability of our own eyesight. The familiar Snellen test for vision thus cannot effectively measure objectively reliable vision. I shall briefly develop this point to illustrate, by way of a concrete example, how effective discernment of conceiver-independent truth is typically unavailable.

The familiar Snellen chart tests the function of the fovea, the most sensitive part of the retina. Clinical use of this chart assumes that the component letters, 'E', 'F', 'P', 'T', etc.—which subtend an angle of 5 minutes of arc at the eye's nodal point—can be identified 'appropriately' by the 'normal eye'. (Incidentally, many people can resolve letters subtending a smaller visual angle; accordingly, the letters on some Snellen charts are designed to subtend an angle of only 4 minutes.) Tests are typically given at a distance of 6 metres, or 20 feet. At this distance, the light rays from the chart's letters are roughly parallel, and the perceiver does not—or at least should not—have to strive to focus. If a perceiver seated 6 metres from the chart reads the line of letters subtending a visual angle of 5 minutes at 6 metres, we say that her vision is 6/6, or (in the foot-oriented United States 20/20). The numerator of the fraction indicates the distance at which the test is given. The denominator denotes the distance at which the smallest letters read subtend a visual angle of 5 minutes.

We cannot plausibly hold that 6/6 vision, by the standard of the Snellen test, qualifies as objectively reliable vision—vision conducive to objectively true visual beliefs. Testing for visual acuity relies on a standard of 'normal vision' determined by reference to how the 'typical human eye' actually operates in resolving the Snellen letters. The standard set by the subtending of a visual angle of 5 minutes arises from what is, liberally speaking, visually typical among the community of human visual perceivers. The 'typical' human perceiver, loosely speaking, clearly sees—without blurring, fuzziness or duplication— three bars of an inverted 'E' when she is standing 6 metres from the Snellen chart. Such visual experience, according to the Snellen test, is the standard for 'normal vision'.

Vision that is normal by the Snellen standard does not obviously qualify as objectively reliable or truth-conducive in a way pertinent to scepticism about realism. Normal vision by the Snellen standard is based loosely on an assumed statistical average concerning human visual perceivers, not on considerations purporting to indicate objective reliability of vision. A sceptic, in accord with Q3, will naturally question whether that statistical average is ever a reliable means to conceiver-independent reality. It is doubtful that we have any non-question-begging reason to hold that it is thus reliable. We cannot presume the reliability of our vision to provide non-question-begging reasons in favour of the reliability of our vision.

More generally, we cannot effectively rely on the deliverances of our belief-forming processes (e.g. perception, introspection, judgement, memory, testimony, intuition and common sense) to test the reliability of those processes regarding their accessing conceiver-independent facts. Appeal to the deliverances of those processes would beg the key question against an inquirer doubtful of the reliability of those deliverances and processes. The belief-forming processes in question need testing, with respect to their reliability, in order to provide non-question-begging support for the realist's claim to objective truth. The realist claims to know conceiver-independent facts about external objects. A doubtful inquirer will naturally

demand an effective, non-question-begging reason for the realist's claim. A question-begging reason will settle nothing in this philosophical dispute.

A sceptic's use of *Q1–Q3* bears on a wide range of positions commonly called 'realism'. This range includes each of the following species of realism: *weak* realism (i.e. something objectively exists independently of conceivers); *common sense* realism (i.e. tokens of most current observable common sense, and scientific, physical types objectively exist independently of conceivers); and *scientific* realism (i.e. tokens of most current unobservable scientific physical types objectively exist independently of conceivers). Michael Devitt has claimed that weak realism is 'so weak as to be uninteresting' ([7.28], p. 22). Even if it is, this is just so much coincidental biography. It does not excuse the realist from providing non-question-begging reasons in support of weak realism. The realist cannot plausibly follow Devitt in appealing just to our current science to settle epistemological debates about realism. The realist must, to defend against the sceptic, explain how our current science gives us the needed effective reason in favour of realism. It settles no philosophical questions simply to say, with Devitt, that 'scepticism [regarding knowledge of conceiver-independent facts] is simply uninteresting: it throws the baby out with the bath water' ([7.28], 63). One pressing question is whether the realist actually has a real baby—i.e. effectively supportable knowledge—to throw out. We cannot simply beg this question, if we wish to make genuine philosophical progress.

Questions under dispute in a philosophical context cannot attract non-question-begging answers from mere *presumption* of the correctness of a disputed answer. If we allow such question-begging in general, we can support *any* disputed position we prefer: simply beg the key question in any dispute regarding the preferred position. Given that strategy, argument becomes superfluous in the way circular argument is typically pointless. Question-begging strategies promote an undesirable arbitrariness in philosophical debate. They are thus rationally inconclusive relative to the questions under dispute. What is question-begging is always relative to a context of disputed issues, a context that is not necessarily universally shared. (For doubts about any purely formal criterion of vicious circularity in argument, see Sorensen [7.100].)

A pragmatic defence of realism, in terms of a belief's overall utility, fares no better than the well-foundedness properties noted above. A variation on Q3 applies straightforwardly: what non-question-begging reason, if any, have we to affirm that a belief's overall pragmatic utility is ever a genuinely reliable means of access to what is objectively the case? Clearly, it does no good here to note that it is pragmatically useful to regard pragmatic utility as a reliable means to objective truth. A sceptic, once again, seeks non-question-begging reasons. Given the aforementioned human cognitive predicament, we can offer little hope for the needed non-question-begging support on pragmatic grounds. Pragmatic support for realism is one thing; non-question-begging support, another. A sceptic demands, but despairs of achieving, the latter.

Even if realism has certain theoretical advantages over various species of idealism, it still must face a sceptic's worries about the absence of non-question-begging supporting reasons. Sceptics doubtful of the correctness of realism need not be idealists holding that an individual's mental activity creates all objects. They rather can plausibly hold that we lack non-question-begging reasons to endorse—to any degree—idealism as well as realism. Scepticism shuns *any* position that does not enjoy non-question-begging reasons; for question-begging support is really no support at all. The burden of cogent argument is now squarely on the realist's shoulders. The future of epistemology will reveal whether that burden is ultimately discharged.[16]

NOTES

1 The first published statement of Russell's abandonment of sense data is [7.86], 305–6. Cf. Russell ([7.92], 100).

2 See Neurath [7.68], 299–318. For a more detailed statement of some of the antimetaphysical views of the Vienna Circle, see Ayer [7.7].
3 Cf. [7.110], 200: 'The verification is not *one* token of the truth, it is *the* sense of the proposition.'
4 For some of the controversy, see Neurath [7.67], Schlick [7.93] and Ayer [7.5].
5 See, for example, Russell [7.82]. For James's reply see his paper 'Two English Critics' ([7.45], 146–53). For discussion of whether James's approach to truth includes a correspondence condition, see Moser [7.58].
6 For an exposition of Lewis's views on the given element in experience, see Firth [7.32] and Moser [7.60].
7 For a bibliography of works on foundationalism, see Moser ([7.65], 273–6) and Triplett ([7.106], 112–16). For some recent attempts to defend epistemic foundationalism of one sort or another, see Pollock [7.72], [7.73]; Cornman [7.27]; Swain [7.104]; Moser [7.59], [7.62]; Foley [7.33]; Audi [7.4]; Alan Goldman [7.36]; and Alston [7.2].
8 For a survey and assessment of some prominent views about the certainty of subjective beliefs about sensations, see Meyers ([7.52], chapter 3) and Alan Goldman ([7.36], chapter 7). Cf. Alston ([7.2], chapters 10, 11).
9 The view that reliable belief-forming processes confer epistemic justification has come to be known is *reliabilism.* Reliabilism of one son or another has been defended by Swain [7.104], Alvin Goldman [7.37], Alston [7.2] and Sosa [7.101].
10 For some indication of these debates, see BonJour ([7.13], chapter 3); Alston ([7.2], chapters 8, 9); and Moser ([7.59], chapter 4; [7.62], chapter 2).
11 For discussion of this and other versions of phenomenalism, see Ayer [7.6], [7.8]; Chisholm ([7.21], 189–97); Cornman [7.26]; and Fumerton [7.34].
12 It is noteworthy that the interpretation of Wittgenstein's *On Certainty* is a matter of controversy among philosophers. For efforts at interpretation, see Shiner [7.98] and Morawetz [7.57]. Another influential proponent of contextualism is Rorty [7.81]. For discussion of Rorty's version of contextualism, see Moser ([7.62], chapter 4) and Sosa ([7.101], chapter 6).
13 For some details on this general approach, see Pollock ([7.73], 180–93) and Moser ([7.62], chapter 6). On the history of the Gettier problem, prior to 1982, see Shope [7.99].
14 Michel Montaigne, 'An Apologie of Raymond Sebond', in *The Essays of Montaigne* (New York, Modern Library, 1933), p. 544.
15 For relevant historical discussion, see Striker [7.102] and [7.103] and Barnes [7.10].
16 A chapter of this size cannot deal with all the movements and issues characterizing twentieth-century epistemology. For some other surveys, touching on some different movements and issues, see Chisholm [7.22] and Hill [7.42]. I thank John Canfield for his comments on a draft of this chapter.

CHAPTER 8
Wittgenstein's later philosophy

John V.Canfield

In thinking he simple. (Tao te Ching)

The early philosophy of Ludwig Wittgenstein (1889–1951) was inspired by the writings of Gottlob Frege and Bertrand Russell. The work of this trio of thinkers forms the stem from which twentieth-century analytic philosophy derives. Wittgenstein's particular influence first showed itself in Russell's 1918 lectures 'The Philosophy of Logical Atomism,' which were, Russell said, 'very largely concerned with explaining certain ideas which I learnt from my friend and former pupil Ludwig Wittgenstein'. Those ideas received their mature form in Wittgenstein's *Tractatus Logico-Philosophicus* (1921). The Vienna Circle philosophers studied this work closely and adopted some of its leading motifs. Rudolf Carnap has been perhaps the most influential of those who initially came under the book's spell. His writings in turn helped shape the position of W.V.Quine, the pivotal American philosopher of the second half of the century.

While elements of the *Tractatus* survive in Wittgenstein's later thought, the two systems differ fundamentally. The later philosophy had its beginnings in Vienna. Wittgenstein, after ventures as a primary-school teacher and monk-gardener, was engaged as an architect when his return to intellectual work was prompted by the Austrian philosopher Moritz Schlick. Starting in 1927, Wittgenstein met occasionally to discuss philosophy with Schlick and others. In 1929 Wittgenstein returned to Cambridge and took up full-time work in philosophy. It was there that his later views grew to completion. Although Wittgenstein never published material from his later thought during his lifetime, his ideas gained currency through his classes, dictated and privately circulated notes (now published as the *Blue and Brown Books*), rumour and various printed reports by others. Those who, through talking or studying with him, were marked by his vision of philosophy, include: Frederick Waismann, Alice Ambrose, Norman Malcolm, G.E.M.Anscombe, Rush Rhees and G.H.von Wright.

The *Philosophical Investigations,* the definitive expression of Wittgenstein's later thought, was published posthumously in 1953. Given Wittgenstein's reputation this book was bound to make an impact on the philosophical community. It was studied closely and mined for insight. It became a major focus of philosophical discussion, and some of its ideas and terms—the terms more than the ideas—became common coin in philosophical discussion. Nonetheless, in the following decades critical response to the book's ideas within the Anglo-American community tended to the negative. Evidently a philosophical world so strongly influenced by the early Wittgenstein left little room for the acceptance of the later philosophy's diametrically opposed position. Thus in the 1950s and 1960s a good deal of Wittgenstein's substantive impact was to provide an adversary view. Throughout this period critics often preferred to deal with the Wittgenstein they found in the secondary literature, thus letting themselves off the difficult job of engaging

the primary text itself. An essay by Kripke on rule-following, which appeared in 1981, inaugurated a more recent period of involvement with Wittgenstein's thought. Again the impact on contemporary discussion came largely through the secondary literature.

I believe the cycle has come round: we are entering a period of sustained concern with Wittgenstein's actual words. This return to the texts is long overdue; they contain riches as yet barely touched. For instance Wittgenstein's insightful *Remarks on Philosophical Psychology* is little studied by philosophers working in that area.

On the other hand, that for several decades now Anglo-American philosophers have tended to ignore Wittgenstein's *Nachlass* as a source of substantive insight is not surprising. Above all there is the difficulty of comprehending him. The challenge will be evident to anyone who looks through the *Remarks* just referred to, for example. It is hard, very hard, to see what Wittgenstein is about. The major obstacle is that he writes always from deep within his unique system of thought. Unless we have some sense of the main contours of that system we will find his prose strangely unintelligible. Each sentence taken by itself may be clear; what is hard to grasp is what the sentences are in aid of. What is Wittgenstein up to?

This essay is an attempt to make clear some of the fundamental ideas and assumptions of the *Philosophical Investigations.* I focus on the 'anthropological' element I find in the *Investigations* and on the book's appeal to the simple.

THE MOVE TO THE LATER PHILOSOPHY

Overall aim

In his early thought Wittgenstein took the goal of philosophy to be 'the logical clarification of thoughts' (*Tractatus,* 4.112). Consequently, 'The result of philosophy is not a number of "philosophical propositions", but to make propositions clear' (ibid.). And again:

> The right method of philosophy would be this. To say nothing except what can be said, *i.e.* the propositions of natural science, *i.e.* something that has nothing to do with philosophy: and then always, when someone else wished to say something metaphysical, to demonstrate to him that he had given no meaning to certain signs in his propositions.
>
> (*Tractatus,* 6.53)

The *Tractatus,* then, is anti-philosophical in intent; metaphysics is hidden nonsense. The *Investigations* also sees metaphysics as resulting from a misreading of language. The philosopher has been fooled by certain surface features of language. Wittgenstein's position is an extremely radical one. He saw himself as the last philosopher, remarking that in philosophy the one who comes in last wins the race ([8.12], 34). Last, because he viewed his work as destroying philosophy, at least in its classical metaphysical form. The cure for philosophical delusion remains the same as in the *Tractatus:* a direct confrontation with the actual facts of language. 'What we do', he says in the *Philosophical Investigations,* 'is to bring words back from their metaphysical to their everyday use' ([8.9], §116). The difference is in the nature of such confrontation. I shall begin by looking briefly at both sides of this contrast, illness and cure.

Grammatical fictions; metaphysical pictures

In the *Tractatus* all sensible propositions are pictures; they portray the way things are. In the later philosophy, in contrast, 'pictures' are the bad guys. They are what lead the philosopher into error: 'A picture held us captive. And we could not get outside it, for it lay in our language and language seemed to repeat it to us inexorably' ([8.9], §115). In the later philosophy, the analogue to the metaphysician is not the truthseeking scientist or austere logician, but rather that hopelessly muddled person, the King in *Through the Looking Glass,* who thinks the Messenger's report that he passed nobody on the road is about a person named 'Nobody'. The King is in the grip of a 'metaphysical picture', his Nobody an example of a 'grammatical fiction'. Because 'Nobody' in the Messenger's report has the look and surface-grammatical position of a name, the King misreads its depth grammar, taking it to be a singular referring expression; that is to say, he thinks 'nobody' refers to some particular person. His resultant, innocently insulting remark to the Messenger, 'So of course Nobody walks slower than you', is in reality not false but senseless. He speaks a word we understand, but uses it in a manner contrary to its nature, and thereby talks nonsense.

Actual metaphysical pictures are of the same type: a mistaken projection of the surface grammar of an expression. Our understanding is befuddled by a false analogy. For instance, one takes talk about one's intention to be talk about a certain mental something or other. The mistake is virtually forced on us by our language. We say things like: 'I intend to go to the store', or 'My intention is to go to the store', or even, 'I have the intention of going to the store.' When, as philosophers, we wonder about the nature of intention, we recall such examples. In reflecting upon them we already unthinkingly assume that if one has an intention, then surely one has *something.* What could that something be? It isn't anything physical, obviously. I couldn't put my intention in a box, or show it to someone. So it must be something mental. Perhaps a thought of my goal, or perhaps a decision—a mental act— to seek that goal. In 'I have lost my watch, but I have the intention of getting a new one', both 'intention' and 'watch' appear to refer to something. That simple false analogy provides the root strength behind the philosopher's subsequent discussions of intention—discussions that get very sophisticated and convoluted, while never transcending their origin in the absurd.

Again, the word 'I' in 'I think…', 'I intend…', and so on, has every appearance of being a referring expression. It is a basic question for metaphysics to settle the nature of that referred-to entity. For reasons I shall touch on below, Wittgenstein denies that those uses of 'I' refer. If he is right, the self of philosophy, the alleged or assumed referent in 'I think…' is a grammatical fiction; the 'I' of the metaphysician is pictured, not conceived.

There are two plausible objections to the points just made. The first is that in the last two examples the alleged nonsense-producing philosophical pictures are in fact correct. Intentions *qua* mental entities and Cartesian selves are real, not grammatical fictions. The second objection is that since no one will willingly give up philosophy, Wittgenstein's contrary attitude is preposterous.

With regard to the first objection, the strength of one's conviction that intentions are inner and that the I is real are acknowledged and indeed insisted upon by Wittgenstein. There would be no point in combating those views if they did not have such a powerful appeal. The theses that Wittgenstein fights against are ones that have a strong hold on anyone who begins to think about such matters. More than that, Wittgenstein's real target is not the elaborations of such ideas that one finds in the history of philosophy or in contemporary writings, but rather the root sources of those ideas: the compelling, deeply held intuitions that, for example, intentions must be inner, and that the I— this thing I talk about when I speak in the first person—is real. Such intuitions or strongly held, basic philosophical or proto-philosophical beliefs are the targets of Wittgenstein's critical examinations.

The general methodological objection, that Wittgenstein must be wrong in attacking philosophy *per se,* is initially persuasive. In one form the objection holds that since Wittgenstein grants the existence of various 'language-games' (see below) he must grant philosophy a role, since it too can be considered a language-game. But before making up one's mind on this point it would be well to comprehend fully the position one is rejecting. An essential part of doing that in the present case is to understand what philosophical 'pictures' are being contrasted with. Perhaps the greatest impediment to understanding Wittgenstein is the difficulty of grasping his positive account of the nature of language— his view of meaning as use.

Use

The major change marking Wittgenstein's later philosophy is a movement from his earlier mentalistic to a social view of meaning. The change becomes apparent if we look at a term central to both the *Tractatus* and the *Investigations*—the word 'use' *('Gehrauch').* If we took the following proposition from the *Tractatus* out of context it would fit right into the *Investigations:*

> §6.211. In philosophy the question, 'What do we actually use this word or this proposition for?' repeatedly leads to valuable insights.

This thesis, for example, seems congruent with the famous claim of the *Investigations* that, 'For a *large* class of cases…the meaning of a word is its use in the language' ([8.9], 43).

But 'use' has undergone a sea change in the transition from the one book to the other, and the agreement here is only on the surface. It is true that in both books *use* is the magical point at which mere signs—mundane things in the world—take on significance, become truly part of language. In the *Tractatus, use* is the mental projection of a propositional sign onto its sense by means of a thought. The view is broadly Fregean, and one finds something similar in such contemporary mentalists as Jerry Fodor [8.62]. In the *Investigations, use* has nothing to do with the mental; rather, it refers to something social. Wittgenstein takes his cue from the obvious fact that language is something exchanged between people. Words pass back and forth, and change the way we interact. For example, a request is made and complied with. Wittgenstein gives this notion of use *qua,* exchange a special interpretation. He holds that the symbol-token is used when it is put in play, when it is uttered in the *language-game*.

The notion of a language-game is perhaps the central term of art of the later philosophy. To understand Wittgenstein one must be able to see language as he did, namely as a collection of language-games. Thus one must understand what a language-game is. But one must also understand how to understand what a language-game is.

A language-game is a custom, a socially constrained pattern of interaction. The word 'game' here emphasizes the fact that word usage is inextricably meshed with human interactions. A word is analogous to a game marker of some son, a chess knight or an ace of hearts. These objects, themselves inert, take on their usual significance when they are in play. Particular patterns of interaction provide an atmosphere within which the objects live and function. Similarly the child's 'Juice!' functions as a demand only within a certain human context, a custom-regulated pattern of interaction where requests are acknowledged and sometimes complied with. But an explanation of 'language-game' in terms like 'pattern of interaction' doesn't take us very far; and the more general issue arises, of how to explicate any of the concepts we come upon in doing philosophy. We are led to questions of method.

But first let me tie together the ideas of 'picture' and 'use' discussed above, in order to state more clearly Wittgenstein's goal in his later philosophy. Higher-level concepts like intention are essentially linked to lower-

level practices; for example, one states what one is up to without using the corresponding high-level word 'intention'. We can approach the understanding of a given such concept either from the top or from the bottom. Here are two series of related utterances ordered from top to bottom. (1) 'I have the intention of going upstairs.' 'I intend to go upstairs.' 'I am going upstairs.' 'Upstairs!' (A child's one-word intention-utterance.) (2) 'I have the belief that the book is heavy.' 'I believe the book is heavy.' 'The book is heavy.' 'Heavy!' (A child's one-word belief-utterance.) Top-down elucidations try to explain or define one high-level concept in terms of others. For instance, 'intention' might be explained by means of 'prepositional attitude', or 'language' in terms, in part, of 'mental representations'. We end up giving elucidations in terms of concepts that themselves need elucidation. But as the child's holophrastic utterances exemplify, we learn to use words to state intentions or beliefs, and so on, before we learn meta-level concepts like that of intention and belief. Fruitful efforts at elucidation, the later Wittgenstein believes, follow that bottom-up order of learning.

We all display a perfect mastery of the ground-level linguistic practices. But we have no reflective knowledge of such usages. We haven't stood back and observed them. Instead, we turn our attention to a word like 'intend' or 'language' and try to think what such a thing could be. In this, Wittgenstein said in the *Philosophical Investigations,* we are like primitive men who form the strangest ideas of their own practices ([8.9], §194). The way out is to turn ourselves into own-culture anthropologists, and actually examine our practices. Examining the basic, lower-level word-uses is the proper way to a reflective understanding of the corresponding higher-level logical words. The result of that examination is to dispel the false picture we form by wrongly projecting words like 'intention', 'belief' or 'I' onto their supposed referent. In general then, confronting the pictures that lie at the roots of metaphysics with a survey of how the related pieces of language actually function is supposed to reveal the fact that our philosophical positions are at their base nonsensical. Thus Wittgenstein [8.9] writes:

> §464. My aim is: to teach you to pass from a piece of disguised nonsense to something that is patent nonsense.

The main exegetical strategy of the present essay is to show that nonsense-revealing method at work, primarily in the example of 'intention' and 'I'.

The reversal

The *Tractatus* was top-down in that it deduced its findings from the most general features of language, as in its famous proof of 'simple objects' (2.0211, 2.0212). It was top-down also in that it stated its results in abstract terms. The *Tractatus's* concern with the simple was thus rather misleading. The simplest proposition, the elementary one, is not known directly, in terms of examples; the latter do not interest the pure logician the author of the *Tractatus* conceived himself to be. One knows only that there are elementary propositions, and that they are made up of a concatenation of simple names that name simple, unanalysable objects. The core of this description is an assumed distinction between naming and saying. But the concepts both of naming and saying, in this special sense, are not given through instances; rather, one presupposes an abstract grasp of the concepts. The later Wittgenstein would say that we have only a misleading picture of such saying and naming, and no real understanding of them.

The reversal of that top-down approach is an essential feature of his later thought. The inversion is announced in this passage from the *Philosophical Investigations:*

> §108…. The [Tractarian logician's] *preconceived idea of* crystalline purity can only be removed by turning our whole examination round. (One might say: the axis of reference of our examination must be rotated, but about the fixed point of our real need.)

The real need is to understand the nature of language—where this is now seen as something that lacks an essence—and to understand those concepts that are central to philosophy. The reversal, I suggest, is the 180-degree turn from top-down to bottom-up. Instead of looking at the concrete and simple from the vantage-point of the abstract, examine and come to understand the abstract in terms of the simple and concrete. And specifically, in terms of *examples* of simple language-use.

The centrality of examples was announced in the *Blue Book:*

> The idea that in order to get clear about the meaning of a general term one had to find the common element in all its applications, has shackled philosophical investigation; for it has not only led to no result, but also made the philosopher dismiss as irrelevant the concrete cases, which alone could have helped him to understand the usage of the general term.
>
> ([8.6], 19)

Wittgenstein claims here that the only thing that will enable us to understand the concepts we are interested in are relevant 'concrete cases'. His emphasis on *simple* examples is evident at many places; it is seen in his practice of philosophy when he turns again and again to simple imagined examples, and when he urges us, at numerous points, to consider how a child might learn a given concept. For example his discussion of *belief* in the *Investigations* ([8.9], 190) opens with the question, 'How did we ever come to use such an expression as "I believe?"' What the child first learns will presumably be simple.

To make Wittgenstein's 180-degree reversal is to adopt a genealogical framework, where sophisticated uses of language are to be understood by comparing them to developmentally related simple ones. The reversal also involves focusing one's concern with language at the level of actual use. This is the basic level where one human engages with another in face-to-face interactions in the flow of daily life.

'Logic' in the Philosophical Investigations

In a way reminiscent of the *Tractatus,* the logician's goal is insight into the nature of language in general, and individual, philosophically important concepts in specific. One major difference is the surrender of the idea of the homogeneity of language, and the allied assumption that language has an essence. We can already see Wittgenstein approaching this result in his transitional 'Some Remarks on Logical Form'. There he abandoned the stance that the logician need not sully himself with actual examples, and tried to look in detail at possible analyses of colour propositions. As a result he had to abandon the idea that the logical rules governing language hold universally, across the board. The rule that if a point in visual space is one colour it cannot be another is now conceived, not as a hidden, truth-functional tautology (not, that is, as an instance of a general logical truth) but as a special rule holding of colour words. But such 'special' rules are still thought of as 'logical'.

The idea of Wittgenstein's transitional writing, as given in the manuscripts published in *Philosophical Remarks,* that words belonged to families, and that language is thus analysable into distinct calculi, with their own rules, developed in his later thought into the idea of embodied calculi, as it were, where words are employed in languagegames. Language thus comes to be conceived of as a collection of language-games. There is nothing in common among these 'games'; nothing that makes them part of language. They have no

shared essence. Rather essence becomes scattered. Each language-game has its own logic, its own unique rules and offices.

Logic remains, as in the *Tractatus,* the deepest part of philosophy. But the business of the logician has changed. It is no longer to investigate the universal presuppositions of propositions—general features of 'logical space'—but to investigate one by one the distinctive properties of the multifarious language-games. There is no longer *a* logical space; each language-game has its own unique logical space. The idea of coming in contact with the simplest case—the atomic proposition— only through abstract and very general characterizations is replaced by the idea of looking at, in the sense of actually observing, various simple examples of words in use. Wittgenstein's changed conception of logic is a natural consequence of his changed views on language. It should perhaps be emphasized that that view of logic is radically opposed to the standard one found in elementary logic courses.

For Wittgenstein the subject matter of logic is broadened enormously. Traditionally logic deals, for the most part, with propositions or truth-claims. From the point of view of someone impressed by the power of mathematics and science such a study would cover what matters in language. In contrast Wittgenstein points to a multiplicity of word uses beyond the scope of traditional logic. The list he gives in the *Investigations* provides only a limited idea of that diversity, but it is a starting point:

> Giving orders and obeying them…. Describing the appearance of an object, or giving its measurements…. Constructing an object from a description (a drawing)…. Reporting an event…. Speculating about an event…. Forming and testing a hypothesis…. Making up a story; and reading it…. Play-acting…. Singing catches…. Guessing riddles…. Making a joke; telling it…. Asking, thanking, cursing, greeting, praying.
>
> ([8.9], §23)

A Wittgensteinian logic takes language in all its variety, and with its full involvement with human life, as its subject. 'Logic' no longer deals with presuppositions common to all our contentful utterances, but with assumptions common to a type of utterance—where the types are counted in terms of language-games. To state the 'logical' presumptions of a given utterance is to describe the 'logic' or 'depth grammar' of the language-game it is uttered in. In one such language-game, for example, we make first-person intention-utterances, and one 'logical feature' of such utterances is that they are governed by a criterion of truthfulness, a point I shall discuss below.

What is the simple, that we might examine it?

The new 'logician,' unlike the old, scorns analysis of the son that tries to explicate a given concept in terms of its supposed meaning-elements. What then corresponds to the simple in the later philosophy, since Wittgenstein no longer believes in that product of analysis, the atomic proposition? What corresponds to elementary propositions, I believe, are what he sometimes calls 'signals'. These are utterances, often of one word, that play a role in a simple language-game, as in the example of the child's request 'Juice!' Instead of atomic propositions, words uttered in simple language-games.

There are two sources for such simple language-games. One is to make them up. The well-known example of the builders ([8.9], §2) supposes that in the only piece of language a tribe has, a builder cries out the names of various materials, such as 'Slab!' or 'Beam!' whereupon helpers respond by bringing the objects named. Such language-games allow Wittgenstein to discuss difficult problems in a sharply focused

way. But his imaginary examples may strike the reader as too schematic; it is hard to connect those simple games with our actual language.

I believe the examples work effectively only when considered along with another type of simple example. Wittgenstein alludes to such examples in his frequent admonitions to examine how a child might learn a given piece of language. (In addition to the example cited earlier, see: [8.9], 200; [8.11], I: §§163, 309, 346, 375.) If we carry out those suggested examinations in detail we can come to see his own made-up examples in the right light and we can gain an understanding of his many 'logical' remarks.

I suggest we drop the 'might' from the question about the child, and replace it with a 'does'—how in fact do children master speech? Observing them doing so can lead to a clear view of the simple language-games that form what is perhaps Wittgenstein's primary paradigm. There the conceptual link between learning and thing learned that Wittgenstein stressed (for example in *Remarks on the Philosophy of Psychology* [8.11], II: 337) becomes plain: observing children coming to a mastery of speech allows us to perceive the details of the language-games they master. Such examples are to be our tutors. They will lead us to an understanding of two things: the puzzling terms of art Wittgenstein employs, including 'language-game' and 'use,' and second, the concepts of central interest to philosophy, such as *intention, reference* or *self.* That appeal to the simple is a Wittgensteinian, bottom-up approach to understanding Wittgenstein. This line of interpretation develops suggestions by Norman Malcolm ([8.34], 133–53) concerning Wittgenstein's claim that language is an extension of action.

It might be argued, however, that there is an element in Wittgenstein's thought inconsistent with a genetic approach. He sometimes makes the point that our present way of speaking and acting could conceivably be what it is independently of what we were taught as children ([8.6], 12). If so, then the connection between the child's early language and the language of the adult would be broken; learning about the former would not teach us about the latter. But here and in similar passages Wittgenstein is talking about a causal connection; he is making the point that one can conceive, for instance, of someone just inheriting a capacity to speak without his having been educated or trained in language. The focus of my concern with tracing paths from the child's language-games to the adult's is not causal; the causes of the adult's speech behaviour are not in question. What is in question is the nature or character—the shape and function—of that behaviour. The hypothesis I attribute to Wittgenstein is that getting clear about the character of the child's language-games tells us something about the adult's. The patterns may be similar, whether or not there is a causal connection between the two. Finding the simple pattern in the more complex, or seeing the more complex as a variation of the simple, provides insight of a sort into the complex. Analogously, examining a primitive internal-combustion machine may help us understand the workings of a later, more complex version even if the later one sprang independently of any prototypes from the mind of its inventor, so that there exists no causal connection between the two variants.

THE ROOTS OF LANGUAGE

Action

I have been underscoring Wittgenstein's primitivism. The present section enlarges upon his appeal to the primitive, in part by introducing a threefold typology of 'proto-type,' 'gestural stage' and 'primitive language-game'. This categorization is implicit in Wittgenstein, and stating it helps us understand him. Some readers may object that the subsequent discussions of language-learning and primate behaviour have no place in an introductory presentation of Wittgenstein, and certainly the discussions will sound strange in comparison to standard accounts. My justification is that the following remarks emphasize two crucial,

interconnected elements of Wittgenstein's later thought that are often overlooked or underplayed. One is his bottom-up approach, the other is his assumption that language is an extension of action.

'Instinctive' behaviour

I have already introduced the first point, and shall start here with the second, in particular with some quotations establishing the interpretive thesis that for Wittgenstein language is an extension of action patterns underlying early speech. The following passage from *On Certainty* [8.13] shows the 'logician' explicitly concerned with the primitive:

> §475. I want to regard man here as an animal; as a primitive being to which one grants instinct but not ratiocination. As a creature in a primitive state. Any logic good enough for a primitive means of communication needs no apology from us. Language did not emerge from some kind of ratiocination.

The essay 'Cause and Effect: Intuitive Awareness' is central for understanding Wittgenstein on the primitive. He writes there, for instance:

> The origin and the primitive form of the language-game is a reaction: only from this can more complicated forms develop. Language—I want to say—is a refinement, 'im Anfang war die Tat' [In the beginning was the deed.]
>
> ([8.8], 420)

Instead of 'primitive form' he later speaks of the 'proto-type' of the language-game (ibid., 421). He speaks of 'instinctive' behaviour, as when a person 'instinctively' (or perhaps better, *naturally*) looks from the effect to the cause, for example looking to see what has just stung him (ibid., 410). He also refers to the 'biological function' of these 'primitive forms' of behaviour:

> The [language-]game doesn't begin with doubting whether someone has a toothache, because that doesn't…fit the game's biological function in our life. In its most primitive form it is a reaction to somebody's cries and gestures, a reaction of sympathy or something of the sort.
>
> (ibid., 414)

Wittgenstein believes we can gain insights into our concepts by examining their roots in primitive or natural forms of interactive behaviour:

> Believing that someone else is in pain, doubting whether he is, are so many natural kinds of behaviour towards other human beings; and our language is but an auxiliary to and extension of this behaviour. I mean: our language is an extension of the more primitive behaviour. (For our *language-game* is a piece of behaviour).
>
> ([8.11], I: §151)

The child naturally comes to participate in the primitive behaviour patterns basic to language. Thus consider the acts and responses connected with request words. At the earliest stage the child simply cries when hungry, or cold, or wet, and so on. Then the mother responds, say by bringing it to her breast, whereupon

the child does its part by suckling. Similarly, there is the interaction pattern of the child's reaching towards something, and the mother's response of handing it to the child.

Such interactions arise naturally, without any drill or explicit instruction, between child and caretaker. They support the development of language, which could not arise without them. I shall call the basic stage of interaction just discussed the language-game's proto-type. The proto-typical behaviour occurs at a stage preceding even the simplest symbol use, as it precedes the simplest use of what I shall call natural gestures.

Intention

In the interaction underlying the child's mastery of intention-language the mother responds to what she sees the child is up to. She might react by calling out a warning, and the child in turn might respond to her fear-laden voice by stopping in its tracks. We might speak here of the child's *projects*—its being engaged in doing something, for example, feeding itself with a spoon, putting small stones one by one into a can or buttoning its shirt. Such actions are paradigmatically voluntary ones ([8.11], II: §270). In the language-game proto-type in question, then, the child is engaged upon some project; the mother observes or anticipates the child's project and reacts appropriately, and the child in turn may respond to that response. This action pattern is rooted in our animal nature, in particular in our ability to anticipate one another's actions and our propensity to respond appropriately. The same anticipation and similar responses are found among apes.

The gestural stage

Natural gestures arise in the context of, and are inseparable from, such proto-type behaviours. An underlying action pattern is modified, emphasized or added to, in a way that brings it to the other's attention, and thus it becomes a natural gesture. For example one might turn an action into a gesture by performing it in the absence of the interactive behaviours normally preceding it.

The biologically based nature of such primitive gestures can be seen in examples from primate studies:

> In order to groom [the chimpanzee infant's] side and armpits, [the mother] takes his arm and pulls it upwards. [Later] the infant…adopt[s] this posture unaided while his mother grooms him…. At the age of 11 months an infant…came up to his mother, sat down in front of her and adopted this posture…. Almost predictably, his mother groomed him.
>
> (Plooij [8.75], 117)

Similarly Plooij speaks of, 'The development by human infants of an arm-raising gesture which at first appears in the infant's repertoire as a passive response to being picked up and later becomes an active request to be picked up' (ibid.).

Here is an example of a natural gesture of intention. A pre-verbal child, moving towards the steps and obviously aiming to climb them, stops, turns its head and makes eye contact with its mother. In doing so the child calls attention to its crawling towards the stairs, using a natural gesture indicative of what it is up to; its look, in that context, signals its intention to climb the stairs. The mother may respond by walking up the stairs behind the child, allowing it to hone its developmental skills while ensuring its safety. The gesture cannot live outside the context distinctive of the

corresponding proto-behaviour. That is, it cannot be *that* gesture outside that particular context. For two reasons. One is that context disambiguates a gesture; the same motion can be a request- or an intention-

gesture, depending upon the context. A second, more radical reason, is that a social group cannot employ, say, a gesture to initiate grooming if they are not creatures that groom one another. Nor give an intention-gesture if they are not creatures who do anticipate and respond to one another's projects.

The simple language-game

The natural gesture seems to say this: take up the usual interaction pattern at this point. There is the interaction pattern of the infant chimp climbing onto the mother to be transported. The gesturing mother is saying in effect, take up the climbing-aboard routine now. Or, in the instance of the baby's stopping to make eye contact: take up the routine of your responding to my crawling to the stairs and climbing them. The gestures are a stylized overlay upon the prior naturally existing interaction pattern.

A further and crucial stylization is made within the same protoforms: one-word language-games develop from within the proto-type or its gestural embellishment. The word is no mere simple embellishment or stylization of the foundational, proto-behaviour. The word *qua* symbol-token is so stylized that its connection with the job it performs is purely conventional, and in that sense arbitrary. Any other short and readily pronounceable or readily perceived token-type would have served the same purpose equally well. This arbitrary thing, the word, or other symbol, replaces the gesture and takes over its function. In moving spontaneously to a use of one of its culture's words the child steps into language.

In the simple language-game the symbol *qua* signal takes over the role of the gesture, which in turn took over the role played by the mother's observation of the child within the proto-typical behaviour pattern. The word stands in for the gesture and does the same job. For instance, the child might say 'up' instead of gesturing with a look; the word, like the gesture, tells the mother what the child is about. Language is thus an extension of an underlying action pattern; and we see the point of Wittgenstein's quoting Goethe's 'In the beginning was the deed.' The symbol is the symbol-token employed in the corresponding language-game. To have a concept—to know the symbol—is to be able to use the symbol-token in the language-game. Grasping a concept is a matter of having a certain skill, not a matter of connecting some idea, 'sense' or referent to a symbol-token.

In being able to speak its intention the child manifests two linked abilities. The first is one shared with any number of animals—it is to evince the behaviour we call acting with an aim. It is to pursue a project. The second ability is, it seems, unique to humans, at least if we confine the contrast to animals in the wild. It is to speak a word or otherwise provide a symbol-token that indicates the end point of the project the person is in fact engaged upon.

While this later ability is (with the earlier qualification) unique, it is but a small embellishment of a capability which is not unique—the talent of indicating one's project by a natural gesture. The passage to speech does not cross some great ontological divide; there is no fundamental difference between us and other animals. In fact, captive chimpanzees can learn to 'express their intentions' in symbols. Here Wittgenstein, as opposed say to Chomsky, is a Darwinian [8.57].

From the primitive to the sophisticated

The child's one-word uses look back to more primitive stages, and forward to sophisticated adult uses. Developments that lead towards our complex everyday talk of intentions include the use of intention-utterances of two or more words such as 'Climbing chair'. The end point of a project is now indicated by several words, one betokening an action and the other the object to be acted on. The function of the intention-utterance—to betoken the project's end point—remains unchanged.

Ordered intention-utterances, such as 'Jump first, then shirt', are another development from the holophrastic phase, as are a child's later conditional intention-utterances, such as: 'When I get to Daniel's I'll have a drink of juice.' Eventually, with the learning of clock and calendar time, the child will come to amalgamate temporal references and intention-utterances to produce statements like 'I'm going upstairs at seven o'clock.'

Simple intention-utterances stand at the base of one of the major branches of our language. Promising, making assignations, exhorting someone, deliberating all presuppose or in some way incorporate the early simple language-game of intention-utterance. In general simple language-customs grow out of proto-typical interaction patterns; in turn the simple customs change, grow and combine into the multitude of complex ones we participate in daily. At the far end of that evolution are language-games of extreme complexity such as theoretical physics, but even these retain their roots in the primitive.

For Wittgenstein a perspicuous way of viewing adult intentionutterances is to compare them with the core interaction pattern present in the language-game proto-type. A statement like 'I'm going out to get a paper' has a clear similarity to the child's 'I'm going upstairs' gesture. Both reflect that earlier pattern of anticipation and response.

The child learns its language by mastering an increasingly complex set of interaction patterns—customs—in which words, like tools, serve various ends, have various functions. This transition to increased complexity and variety nowhere requires a passage from word use to mentally resident concept. The players learn more language-games and more complicated ones; but that never requires any inward, mental playing.

Third-person intention-statements; syntax

The one-word intention-utterances I have described are first-person uses. The child also masters third-person uses attributing intentions to others. The distinction between the two types of use is critical and I shall discuss it later in the section on *Äusserungen* (pp. 269–71). Here I shall confine myself to a few observations about 'I'.

To master the third-person uses the child must learn to deploy two distinct criteria. One governs whether or not the person referred to has the intention in question. Here the child will rely upon what it observes, including what the described person may say. The second criterion concerns the identity of the described person. The child must be able to pick out the person named 'Daddy' or referred to as 'you', and so on. Neither of these criteria operate in the first-person case. The child does not base its intention-utterance on self-observation, or, of course, upon hearing its own utterance. Nor does it deploy some criterion to establish that it is the person whose intention is being stated. As Wittgenstein put it, the speaker here does not choose the mouth through which it speaks ([8.6], 68). Similarly, when the child indicates what it wants by a gesture, it does not choose the arm with which it points. It simply points, and in the other case, it simply says 'Upstairs'.

Consider the syntax of first- and third-person intention-statements. The regimentation of syntax operates upon symbol-token uses. In the simplest third-person intention case two functional elements are regimented, one betokening the end point of the person's project, the other indicating whose project it is. In 'Daddy upstairs', both functional places are filled. 'Daddy is going to go upstairs' is a correctly regimented, or grammatical, version.

In the first-person case the regimentation of grammar requires that a word occur where there is no corresponding function. Here the child initially does not betoken itself; and as far as function goes there is not and need never be a need for such a betokening. The child employs no criterion of identity to pick itself out; and the hearer, being in the presence of the child, and observing that it is the child who speaks, needs

no word to tell it who is speaking. The child's 'Upstairs' matches functionally the role the utterance plays. But grammar requires regimentation into subject and predicate, and so the child learns to embellish its 'Upstairs' and to say instead something along the lines of 'I am going upstairs.' These reflections lay the ground work for understanding Wittgenstein's rejection of the idea that 'I' is a referring expression.

TERMS OF ART

I shall now show how the examples discussed above shed light on some of the later Wittgenstein's ideas.

Use; language-game

To use a word is to utter it in a language-game. But what is a language-game? A folk-philosophical criticism of Wittgenstein is that he fails to answer that question, in that he supplies no 'criterion of identity' for 'language-game'. What he fails to supply, presumably, is some topdown account of when something counts as a given language-game. By his own lights, however, Wittgenstein does not owe us a top-down elucidation of 'language-game'. Defining his technical terms by means of one another is bootless; defining them in a non-circular way in ordinary speech or in someone else's system is impossible. What one really needs to learn is how to use the term; and one can. The proper answer to 'What is a language-game?' is: this is one, and this, and this, and so on. Presented thus the answer may seem lame, but it is another matter if the this's refer to detailed and closely examined examples, for instance of the sort indicated in the previous section. The answer to the objection then is to reject the possibility of a useful top-down definition or analysis of 'language-game'. The concept is to be communicated rather by means of examples and remarks about them.

In introducing the term 'language-game' in the *Investigations,* Wittgenstein appeals to examples from a child's mastery of language. He writes:

> §7. We can also think of the whole process of using words in (2) [the slab-beam language] as one of those games by means of which children learn their native language. I will call these games 'language-games' and will sometimes speak of a primitive language as a language-game.

When Wittgenstein says, 'I call these games "language-games"', the reference class is 'games by means of which children learn their native language'. But the latter phrase is misleading. Wittgenstein does not mean merely that the 'games' in question have the heuristic function of getting the child to learn some further piece of language. Rather, what the child learns in those cases *is* language—primitive, simple, but *bona fide* language.

In the *Blue Book* Wittgenstein introduces 'language-game' as follows:

> Language-games are the forms of language with which a child begins to make use of words. The study of language-games is the study of primitive forms of language or primitive languages.
>
> ([8.6], 17)

Here it is less obvious, but nonetheless true, that the explanation is in terms of examples; on the other hand the passage says more clearly than does the *Investigations* §7 that the paradigmatic instances are children's simple language-games. His reason for introducing the idea of a language-game, and thus turning our attention to the phenomena in question, is also made clear in the *Blue Book:*

> When we look at such simple forms of language the mental mist which seems to enshroud our ordinary use of language disappears. We see activities, reactions, which are clear-cut and transparent. On the other hand we recognize in these simple processes forms of language not separated by a break from our more complicated ones.
>
> ([8.6], 17).

I have mentioned only a few such 'simple forms of language'. A more complete answer to the question 'What is a language-game?' would consider numerous others. A fundamental tenet of Wittgenstein's is that language-games are widely diverse.

Wittgenstein's use of 'use' is also to be learned through examples, and indeed the same ones as before, 'use' and 'language-game' being linked terms. Certain words *qua* sounds take on 'meaning' by being used, that is by being proffered within a language-game. Wittgenstein's use of 'use' is peculiar to him, being parasitical on his unique conception of a language-game.

Function

This word is used originally with regard to artifacts and machines. Biologists apply it, by analogical extension, to animals and plants. Wittgenstein further extends its use to the case of words that play a role in language-games (see, for example, [8.9], §555).

In its original use 'function' is applied at three different locations. Parts of an artifact have functions in so far as they contribute to the functioning of the whole. The artifact itself has a function. We also speak of the function of a function: of the role an artifact with a particular job plays in the life of the people who employ it. This stoneage tool drills holes in rock, but what did the people who made it want such holes for?

Different words, like the various parts of an artifact, function differently in a given utterance. One word in a sentence may indicate when something will be done, and another what that something is. Or compare the various jobs of the words in Wittgenstein's example of the request 'Five red apples' ([8.9], §1). The various language-games themselves have functions—for instance to state intentions, or requests. And that a language-game has such a function may be useful for a people in various ways.

Some characterizations of Wittgenstein on 'usefulness' collapse that threefold distinction of function of part, function of whole and function of function (for example Kripke [8.68], 294).

Family resemblance

As noted, the later Wittgenstein rejects his earlier search for the essence of language, in the sense of some feature or group of features necessary and sufficient for something to count as speech. He compares the concept of language to that of a game. What do all and only games have in common? One will be unable to give a non-circular answer. Examining various games will reveal the same sort of thing one might find in examining a family portrait. Granddad and Junior may have the same-shaped nose, Junior and Sally may have quite different noses but closely similar eyes, and so on. In the case of games this means that something is admitted to the family not because it has the common and defining features of a game; there are none. It is admitted rather because it has some of the properties of standard examples of games. Wittgenstein is not saying we cannot distinguish games from other things. Warfare is no game, nor is ordering pizza, and so on. We distinguish games from non-games but not on the basis of necessary and sufficient properties. When all the features of some newly invented activity are plainly visible and noticed, to call the thing a game is not to make a hypothesis, but rather to make an implicit decision to count this in

the class of games. Wittgenstein thinks that in addition to 'language' and 'game' many ordinary concepts are of the family-resemblance type. 'Rule' and 'expectation', for example.

Criteria

As ordinarily used a 'criterion' may be evidence or it may be something stronger. In the *Blue Book* Wittgenstein says he shall use 'criterion' in that second way. Thus he distinguishes symptoms of angina from phenomena that establish the presence of angina in virtue of rule of language. Suppose that angina is defined by medical science as 'an inflammation caused by a particular bacillus' ([8.6], 25). Then:

> I call 'symptom' a phenomenon of which experience has taught us that it coincided…with the phenomenon which is our defining criterion. Then to say 'A man has angina if this bacillus is found in him' is a tautology or it is a loose way of stating the definition of 'angina'. But to say, 'A man has angina whenever he has an inflamed throat' is to make a hypothesis.
>
> (ibid).

The many discussions of criteria in the secondary literature sought to establish more clearly what Wittgenstein's conception is. In doing so they concentrated on the example of pain, which does not fit too well with the symptom-definition distinction just presented. Wittgenstein was widely believed to have accepted two claims: (1) the criteria for a person's being in pain are behavioural, but (2) the behaviour in question may be present even though the person is not in pain (it might be a case of pretence, for instance). How, in the face of the phenomenon of pretence, could it be a 'tautology' that someone's behaving in the way normally indicative of pain really is in pain? To surmount the difficulty it became common to say that Wittgenstein accepted behavioural criteria for psychological predicates, but held some fancy view about the nature of the connection between criterion and inner state. He was said by some, for example Gordon Baker [8.53], to have discovered a new logical relationship, halfway, as it were, between empirical support and entailment. Some called the relationship that of 'necessary evidence': that such and such behaviour is *evidence* for saying a person is in pain is itself a necessary or conceptual truth (Hacker [8.25]). Again, the alleged virtue of the 'necessary-evidence' interpretation of criteria is that it saves us from a wrong commitment to definitional criteria in cases like pain-allegation.

Wittgenstein, however, gives a different account of the phenomenon of pain-attribution, one that reflects the developmental or genealogical aspect of his thought. He writes, for example:

> If pretending were not a complicated pattern, it would be imaginable that a newborn child pretends.
>
> Therefore I want to say that there is an original genuine expression of pain; that the expression of pain therefore is not equally connected to the pain and to the pretence.
>
> ([8.15], 56)

The language-game allowing judgements of pain comes before—is logically prior to—one allowing judgements of pretence. When Wittgenstein says that the behavioural expression is not equally connected to the pain and to the pretence, he means that the fundamental connection is to pain; the behaviour can only be counted as pretence against a further complicated background of conditions that block the normal move to an ascription of pain.

The person who applies a criterion does so while situated in certain life circumstances, as a fly-fisher casts a line while standing in a stream. The person need not be able to describe the circumstances; need not

even be aware of them as such. They are the place he operates from. For a criterion to be met those circumstances—of everyday normal life—may be required. The mother who judges her child to be in pain does so against a background of such normal circumstances. She makes the judgement without first establishing that those circumstances obtain. It is a rule of language—a truth of implicit definition—that in those circumstances that behaviour establishes that the child is in pain. There is no need here to appeal to a special relationship of 'necessary evidence'. This is so even though we can imagine a case where what appears to be identical behaviour is present and the pain absent (Martians secretly substitute an android for the baby, and so on). In other, more complex cases, indecisiveness is built into the rule governing the application of psychological predicates. In some such cases the rule dictates there is no telling—say about whether a person is sincere or pretending ([8.15], 59).

Questions of circumstance enter into philosophical discussions of criteria in another way. Philosophers' debates over 'personal identity' often deal with questions like this: if Jones enters a matter-transportation booth, disappears, and an identical person appears in the receiving station, is it Jones? If two identical people appear in two receiving stations, is either Jones? Are both Jones? Here the philosopher appeals to our intuition to make judgements about such cases; the philosopher then tries to discover criteria of personal identity that capture those intuitions. If as Wittgenstein believes ([8.9], §80) criterial rules govern judgements only within normal circumstances of application, such appeals to intuition are bogus; in making judgements about those outré cases one is, by implicit stipulation, extending the rule to cover those cases. Before such extension the questions have no right or wrong answer, because our concepts are geared to work in the world as it is and do not come complete with a decision procedure for every possible case. So the interesting question is not what our intuitions are, in such cases, but rather what stipulative extensions of the normal concept those intuitions presuppose.

Äusserungen

This is one of the later philosophy's most significant technical terms; it is used in contrast with certain closely related *descriptions.* Writers have discussed *Äusserungen* under the rubric 'avowals'. I find that term misleading and since I can discover no suitable single English rendition, I shall use the German. As an approximation (but see the caveat below) *Äusserungen* may be defined as first-person present-tense psychological assertions. 'I am in pain' and 'I intend to go' are *Äusserungen;* 'I was in pain', 'He is in pain', 'I intended to go,' and 'She intends to go' are descriptions. The distinction between *Äusserungen* and descriptions is at the core of Wittgenstein's philosophy of psychology.

Whether something is an *Äusserung* is not solely a function of syntax. A sentence such as 'I am afraid' may sometimes express an *Äusserung* and sometimes not. If my words are as it were a groan of fear, they are an *Äusserung;* if, in contrast, they report the results of my reflecting on how I have been behaving during the day, they constitute a description ([8.11], I: §832; II: §156). In the latter case my words are a description since they are based on my observations or remembrances of how I have been acting.

In its primitive, one-word form an *Äusserung* replaces a gesture inside some language-game proto-type. An exaggerated or deliberately prolonged groan of fear might be replaced, in a later case, by a word like 'Afraid!' Or the looking gesture I have discussed by the word 'Upstairs!' The word in each case is no more a description than is the gesture it replaces. The first gesture says in effect, 'Take up the responding-to-my-expression-of-fear behaviour', and that is no description of an inner state. Similarly for the other case. If 'I am afraid' serves the same function as 'Afraid!' in the above example, then it too is an *Äusserung.* Assertions of third-person psychological predicates function differently; for one thing, they are subject to distinctive truth-criteria. Thus my judgement that *she* intends to go upstairs will normally be made on the

basis of observation of her behaviour. Perhaps she told me where she is going, or I saw her get up and move towards the stairs, obviously intending to climb them. My first-person intentionutterance—at least in the standard case reminiscent of the child's one-word intention-utterances—is not based on observation. 'I intend to go upstairs' is not said on the basis of my seeing how I behave, nor on the basis of looking within and becoming aware of some inner intention-state.

One reason for thinking that utterances like 'I intend to go!' do nevertheless describe the inner is that the one who makes them is certain they are true; whereas with regard to third-person remarks like 'She intends to go' there is uncertainty: perhaps for all I know she does not really intend that. The alleged explanation for this asymmetry is that the speaker is directly aware of his inner state of intention, while he cannot be aware of the inner states of another person. Wittgenstein's concept of an *Äusserung* yields an alternative account of the asymmetry. The idea is that the certainty in the first-person case is a feature of the language-game in which the utterance is made. In particular, *Äusserungen* are governed by what he calls a criterion of truthfulness: unless the speaker is lying or otherwise fooling around, what he says is true ([8.9], 222). The language-game itself allows no room for an honest mistake. This feature carries over from a stage in the unfolding of language that precedes doubt and uncertainty. This is an early phase, encountered in simple language-games of children where questions of uncertainty or doubt simply have no place. The question 'Does it really want that?' makes no sense in reference to the child from an earlier example who is making a grasping gesture directed at a toy. When the child has learned to ask by name for things, doubt and uncertainty are still precluded. In context the child's request 'Ball!' allows no uncertainty about what it seeks. That early pattern of request and response can be altered later into one where doubt is in order. A psychoanalyst may doubt the truth of a patient's desire-report, while granting its sincerity. But now a new twist has been added to the language-game; new criteria introduced. The primitive stage—the original languagegame—is not outgrown. The earlier use of request words survives and is honoured throughout the speaker's life; it is the main branch from which the psychoanalytic pattern is an offshoot. Similarly, at any stage we may revert to a language of gestures in order to communicate, as we might have done as children, what we want from another. The language-game of a bygone time may once more be in play, just as the simple language-game, with its criterion of sincerity, is often in play between adult speakers. When the child has mastered the relevant piece of language there is no room for doubting whether it really is afraid when it sincerely says it is—on the assumption that its 'I am afraid' can be seen as a replacement for the earlier, primitive, *Äusserung* 'Afraid!' Whereas in the *description* 'I am afraid', based on self-observation and memory, a sincere mistake is possible.

Äusserungen do not describe the inner. That feature was noted in my previous discussion of intention-utterances. That intention-*Äusserungen* do not function to point to something internal to the speaker is shown by the fact that the hearer has no interest whatever, here, in the inner life of the speaker. Be that as it may, the important point for the hearer is what the speaker is up to. *That* is what the speaker wishes to communicate, and what the hearer responds to by some appropriate act. We can observe the feature in question quite clearly when we consider simple language-games of the kind discussed earlier. Wittgenstein puts the point graphically:

> Does something happen when I…intend this or that?—Does nothing happen?—That is not the point; but rather: why should what happens within you interest me? (His soul may boil or freeze, turn red or blue: what do I care?)
>
> ([8.11], I: §215)

The distinctiveness of first-person psychological utterances is important for Wittgenstein because the mistaken idea that *Äusserungen* are descriptions leads to philosophical confusion. If for example 'I am in pain' describes something, it must obviously be something inner; and thus is born the idea of pain as an inner object. And so too for the range of psychological terms of interest to philosophy, including intention and belief. In short the 'logical' observation that intention-utterances and the like are not descriptions helps destroy the false picture of those utterances that underlies the metaphysical hypostatization of mind.

The bedrock of language

Section 201 of the *Philosophical Investigations* reads in part:

> There is a way of grasping a rule which is *not* an *interpretation,* but which is exhibited in what we call 'obeying the rule' and 'going against it' in actual cases.
>
> Hence there is an inclination to say: every action according to the rule is an interpretation. But we ought to restrict the term 'interpretation' to the substitution of one expression of the rule for another.

Wittgenstein's point is that the instances in which we interpret something—whether a rule, or a remark—are underwritten by cases in which we simply act according to a rule, or simply respond to a remark.

In a normal case the mother does not interpret her child's reaching and pointing gesture; she simply responds, perhaps by giving the child the object it wants. She reacts similarly to the child's one-word request-utterance. The language-game is one of verbal act and response: complying, refusing, pointedly ignoring, suggesting an alternative, and so on. One pitches, the other catches. It is like a baboon troop-leader's gestural offering to carry one of its females past a dangerous point; a matter of gesture and, immediately, response.

A rule of the simple language-game is that the mother's response centres on the object the child has named; *that* is what she gives the child, or what she refuses it, and so on. Once the language-game has been established, the mother's behaviour constitutes a 'way of grasping a rule which is not an interpretation but which is exhibited in what we call "obeying the rule"'.

The bedrock of language is such patterns of action and response comprising the simple language-games and their more elaborate forms. Questions of whether a word should be interpreted this way or that, or of whether a certain action is in accordance with a given rule, presuppose those earlier forms, where questions of interpretation have no place.

Those basic interaction forms count as customs:

> To obey a rule, to make a report, to give an order, to play a game of chess, are *customs* (uses, institutions).
>
> ([8.9], §199)

If we add 'to make a request', and 'to state an intention' we can see more clearly the truth of that remark. Simple language-games are customs, in that they are elaborations of naturally existing interaction patterns. In these elaborations certain arbitrary elements—words—play a role. That these words function as they do is not solely a matter of some natural or instinctive bit of behaviour being implemented. Rather it is in part a question of what the customary usage is; a matter determined by the culture. Another tribe will employ another word. But the language-game proto-type in which the various alternative words function is common to the different tribes:

> The common behaviour of mankind is the system of reference by means of which we interpret an unknown language.
>
> ([8.9], §205)

To interpolate some inner activity of meaning assessment that supposedly mediates between, say, the hearing of a request and the response to it is to add a head to the head we already have (to borrow an expression). This sort of interpolative fallacy is plain in the following example. To explain a baby's smiling at the appearance of its mother one might suppose—some social scientists have indeed hypothesized— that the baby inwardly consults a series of stored images of those it favours, compares the images to its present visual perceptions and smiles when it gets a match (Sroufe and Waters [8.80]). But then how does it recognize a match between perception and image? Does it do so by interpolating a series of images of matches between face-images and face-perceptions? That way lies an infinite regress. But if one supposes the baby just does recognize the match between image and perception, why not suppose that it just does recognize its mother? That the baby responds in that way to its mother, to the one who has fed and protected it since its birth, appears a basic feature of human biology. The inner machinery alleged to explain that response does no real work. The natural, just plain recognition of its mother, its just plain smiling in that situation, *sans* benefit of any supposed inner intermediaries, is a model for language response, in Wittgenstein's view. For example our ability, when raised in some normal social context, to signal where we are going by uttering a certain sound is one of our natural talents; we do it, just as we, or for that matter any number of other animals, just often do anticipate, in the basis of what we see, where another is headed. And here don't think of anticipation as something mental, something inner.

Private language

The most famous sequence of passages in the *Investigations*—roughly sections 243 to 315—opposes the possibility of a private language. The topic has raised a huge exegetical literature. In considering the subject the first question to be asked is: what does the private-language argument repudiate? Intuitively the idea is this. We naturally suppose that pains, thoughts, emotions, and the like, are inner things of some sort. As such they are private in a special way. Someone might have a pain exactly like this one of mine, but cannot possibly have *it.* I might let some made-up word or mark stand for that private object. The word says in effect 'There is *this!'* Now while the *this* lies forever beyond anyone else's grasp it is certainly within mine. My word for it would belong to a private language of the sort Wittgenstein sets himself against. The topic is important because the possibility of such a private language is a natural consequence of an assumption that Wittgenstein again and again rejects—the postulation of the existence of a realm of special, mental entities.

Where I spoke above of an intuition Wittgenstein would speak of a 'picture'. Our ordinary day-to-day speech, where we issue both ground- and meta-level statements, stands in contrast to metaphysical parlance where we employ everyday words but understand them in terms of some misleading picture and thus in a manner contrary to their actual depth grammar. A 'private language' is above all something we picture.

In the following well-known passage in the *Investigations* the distinction between ordinary speech and metaphysical picture is crucial:

> §256…. What about the language which describes my inner experiences and which only I myself can understand? *How* do I use words to stand for my sensations?—As we ordinarily do? Then are my words for sensations tied up with my natural expressions of sensation? In that case my language is not a 'private' one. Someone else might understand it as well as I.—But suppose I didn't have any natural

> expression for the sensation, but only had the sensation? And now I simply *associate* names with sensations and use these names in descriptions.

If we use 'pain' or 'fear' as we ordinarily do, then the manner of its use can be studied in simple language-games. Natural expressions of pain are responded to, as are such natural gestures as a deliberately emphasized grimace. The child learns to replace natural expressions or gestures with words from the common vocabulary. The private-language argument does not deny such pain-claims. Indeed, how could it? Everyone will understand the child's 'It hurts' just 'as well as' the child does, and all will grant its truth: a move made in one of our common and important language-games occasions one of the usual responses. This is not to say that Wittgenstein offers or requires a behaviouristic account of pain-utterances. If the latter were used to express some behavioural facts, then the person's 'It hurts!' would mean something like: 'I am behaving in the is-in-pain way.' But the speaker is talking about his pain, not his behaviour: '§244…. The verbal expression of pain replaces crying and does not describe it'.

What about the meta-level case? Hearing Joe say 'I have a pain in my finger', I remark that he referred to something inner and private. If that gloss has its ordinary use, then, naturally, Wittgenstein would not deny it. For example, my remark might be addressed to someone who is learning our language; it tells him Joe's words were categorically different from a statement like 'I have a splinter in my finger': they were not about anything discernible in space and time. To call pain an inner private state will be to say in effect 'Don't ask anyone to show you their pain or make it available for observation.' Here the objection comes immediately: 'You have it backwards! One cannot make one's pain available for observation because it is inner!' That at least is one's intuition, one's strong conviction. But convictions can be wrong. Perhaps the matter is as Wittgenstein says:

> §248. The proposition 'Sensations are private' is comparable to: 'One plays patience by oneself.'

That one plays patience (or solitaire) by oneself is true in virtue of the rules of that game. Analogously, 'Sensations are private' only describes a feature of our language-game with sensation words; it does not express a deep metaphysical truth, despite our strong temptation to think it does. It is a meta-linguistic or grammatical remark, not a philosophical one.

In §256 the possibility is posed of a piece of language that refers to pain while yet being independent of the natural expression of pain. It is precisely when we grant that possible independence that we enter the realm of metaphysics. That we must grant the possibility seems obvious. Given the metaphysical picture of the private object, it should be possible to introduce words that refer to such objects, regardless of whether I give natural expression to them. Here the metaphysical picture understands 'pain' on the analogy of 'splinter'; it takes it to refer, but of course not to anything public.

The aim of the private-language argument, then, is not to deny that people have pains and the like, nor to insist on a behaviouristic rendition of such mundane facts. Nor does Wittgenstein reject the claim, in natural speech, that sensations like pain are inner or private. Wittgenstein's job rather is to make hidden nonsense plain.

The difficulty of the task is directly proportional to the strength of one's conviction that, for example, *this* —the headache I now contemplate—is something I directly experience, something directly before the mind's eye, as it were. What could be more plausible than that assumption of direct acquaintance? The 'private-language argument' has its work cut out for it.

Section 258 gives what has been taken to be the central formulation of the private-language argument. There Wittgenstein considers the assumption that the ordinary use of mental words is abrogated while yet

one succeeds in referring to the mental, by means of privately set-up ostensive definitions. He says, in the voice of his alter ego:

> —But still I can give myself a kind of ostensive definition….

Granted one cannot point to the sensation in the ordinary way, but rather, alter-ego goes on:

> I speak, or write the sign down, and at the same time I concentrate my attention on the sensation—and so as it were point to it inwardly.

In his own voice Wittgenstein now observes that the foregoing process seems merely an empty ceremony. What is it supposed to accomplish? Alter-ego's reply is that the inner pointing 'serves to establish the meaning of the sign' (that is, in Wittgenstein's example, the sign or mark 'S' which allegedly demarcates the inner sensation in question). The inner pointing achieves that because by its means 'I impress on myself the connection between the sign and the sensation.' And now comes the famous *reductio* that has been taken as expressing the core of the 'private-language argument' and that has been the subject of so much exegetical controversy:

> §258…. —But 'I impress it on myself can only mean: this process brings it about that I remember the connection *right* in the future. But in the present case I have no criterion of correctness. One would like to say: whatever is going to seem right to me is right. And that only means that here we can't talk about 'right'.

On one way of reading these remarks they express a verificationist argument. I can't verify that I am correct in calling this present sensation 'S' since the sensation used to define 'S' is *ex hypothesi* no longer present. What I can't verify is meaningless; therefore the idea of a private language is meaningless. Judith Jarvis Thompson [8.81] attributed such a verificationist reading of Wittgenstein to Malcolm, and repudiated it on the grounds that the presupposed verificationist test of meaningfulness is unacceptable.

In a famous paper Saul Kripke offered an alternative, non-epistemic account of the inner workings of the private-language argument. Kripke tried to displace the exegetical focus of the private-language discussions by holding that the real argument gets expressed already in §202:

> What is really denied [by Wittgenstein in §202] is what might be called the 'private model' of rule following, that the notion of a person following a given rule is to be analyzed simply in terms of facts about the rule follower and the rule follower alone, without reference to his membership in a wider community.
>
> (Kripke [8.68], 206)

Thus Kripke reads the private-language argument as a straightforward inference from the idea of rule-following: the concept of a private language is inconsistent, because using language entails following rules, and following rules entails being a member of a community. This line of interpretation has prompted a discussion in the secondary literature over the so-called 'community view'. The issue under debate is, roughly, 'Did Wittgenstein believe that the idea of a forever solitary rule follower is a conceptual impossibility?' The issue, like the broader one of the exact nature of the private-language argument, remains unresolved.

Both the verificationist and the no-solitary-rule-follower interpretations present arguments of a kind I think are antithetical to Wittgenstein's general approach to philosophy, which seeks not quick knock-down refutations but slow cures of philosophical perplexity. On a more promising interpretation offered by Anthony Kenny [8.67] Wittgenstein is said to deny that the would-be private diarist has succeeded in attaching meaning to his sign 'S'. The problem is not the verificationist one, that the original sensation used to define 'S' is irretrievably lost in the past. Put it this way: even if God could look inside the diarist's mind, and even if God, unlike the diarist could directly access the now past sensation used in the alleged ostensive definition of 'S', still God would not know whether to call the present sensation 'S', for the term has not been properly defined—has not been given a meaning.

But what would be Wittgenstein's reasons for denying the success of the alleged private ostensive definition? One has to do with the *Investigations'* discussion of ostensive definition, as Kenny points out. Wittgenstein's idea is that for an ostensive definition to succeed there must already be in place some language-game within which the defined term plays a role. As Wittgenstein once put it: 'Ostensive definition explains the use of a word only when it makes one last determination, removes one last indeterminacy' ([8.7], 447, 448). One last indeterminacy, that is, within some presupposed language-game where the term being defined will have a use. For example one might know everything about playing chess up to this last point: what shape piece is called the 'king'? The next step then would be to justify Wittgenstein's rejection of the idea of a 'private' language-game. The nub of this suggestive approach is to get clearer on Wittgenstein's view of the nature of *public* language. The denial of private language would then entail pointing out differences between the public and private cases that justify withholding the application of the term 'language' to the latter.

METHOD AND SCOPE

'The right method of philosophy'

I shall rehearse the general methodological points made at the beginning of this essay; after the previous discussions they may appear more credible. A metaphysical problem arises as the result of our viewing some part of our language in the light of a false analogy. The result of that misreading is a metaphysical picture; the entity called into being through that picture is a grammatical fiction. If the picture is seen for what it is, the metaphysical problem will vanish. That one is in the grip of a metaphysical picture, or that correspondingly one is engrossed by a grammatical fiction, will become apparent upon a close look at the language that has misled one. So the right method in philosophy is to confront those 'pictures' with an examination—along Wittgenstein's lines—of the use of the underlying, puzzle-generating words ([8.9], §116). In this therapeutic enterprise the logician who examines language and the metaphysician who is confused by it are one and the same. The *Philosophical Investigations* is a 'dialogue' between the author and his alter ego. 'Nearly all my writings', Wittgenstein said, 'are private conversations with myself. Things that I say to myself *tête-à-tête*' ([8.12], 77). The metaphysical temptations Wittgenstein deals with are ones he has succumbed to or has felt the strong pull of. The 'therapy' he advocates is to be applied by the reader to himself or herself, on the assumption that the same linguistic pitfalls lie in wait for everyone. The first step is to feel the full force of the metaphysical picture. The strength or psychological force of the picture gives the therapy its significance.

Wittgenstein and academic philosophy

Wittgenstein seldom speaks directly to the problems and issues that occupy academic philosophers. Those have been raised to levels of sophistication that would not immediately concern him. He thinks there is more to be learned in the valley of stupidity than on 'the barren heights of cleverness' ([8.12], 80). His work is nevertheless relevant to professional philosophers, if their sophisticated issues have their roots in naive misreadings of language.

In one present-day controversy it is alleged that the ordinary person, in speaking of his beliefs, desires, intentions, reasons, and so on, is deploying a rudimentary psychological theory, so called *folk psychology* (Fodor [8.63]). Another way of putting this is that the folk psychologist—Everyman—deploys a naive 'theory of mind'. That is, in saying what someone believes, and so on, people utilize a theory that attributes to the speaker or to others certain mental states, where these are taken as *causes.* Thus if I say I'm going to be at the airport at 3.00 p.m. you take me to be describing an inner state of affairs, an intention *qua* mental state that will cause me to show up at the airport at 3. One controversy in the literature is over whether folk psychology, so understood, is substantially true or not.

Wittgenstein's work undercuts the discussion pro and con folk psychology, by showing that everyday claims about intentions, and so on, are not claims about the causal connections holding between mental entities. They cannot be, for they are not claims about mental entities. The philosopher, in the grip of a metaphysical picture, is wildly mistaken in his reading of the ordinary person's claims. And it doesn't help that the ordinary person, if the question were posed to him, would say, like the philosopher, that in speaking out his intention he is describing an inner cause. That he would is taken by the philosopher as one of those 'intuitions' that support his interpretation. It would be taken by Wittgenstein not as data but as the expression of a picture; it would show only that the picture has deep roots in our language, and a strong appeal for anyone who begins to reflect philosophically upon such things as intentions and beliefs.

Science-minded philosophers who speak of the mind and its objects—thereby employing the vocabulary of seventeenth-century metaphysics in the alleged context of philosophy-*qua*-science—avoid being thought unscientific by holding out the possibility that someday talk about minds may be replaced by talk about brains. But if Wittgenstein is right the route they take to the brain goes by way of a grammatical fiction. Intentions, for example, are misread as mental entities, and those mental things are projected, in turn, onto the brain. The brain-equivalent of an intention *qua* mental state is a grammatical fiction once removed.

The scope of Wittgenstein's critique

Not only philosophers philosophize. Science and especially social science contains conceptual claims and presuppositions that are philosophical at heart. For example neurobiologists explicitly address 'the mind-body problem,' and attempt to find explanations for 'consciousness' (Horgan [8.66]). Again, scientists attempt to discover if vervet monkeys have a 'theory of mind'—a notion derived directly from that of a 'folk psychology' (Cheney and Seyfarth [8.60], 205).

One might speculate that a full generalization of the intention case I have discussed at length will stand up: beliefs, desires and reasons, understood as mental something or others, will turn out to be, on examination, grammatical fictions. Then a well-known remark of Wittgenstein's would be borne out:

> In psychology there are experimental methods and *conceptual* confusion.
>
> ([8.9], 232)

And the same sort of radical conclusion would hold for examples from neurobiology and animal studies. Experiments or empirical observation on the one hand, hidden nonsense on the other. But speculation here is of little value. What is needed, rather, is to test our deeply felt metaphysical 'intuitions' about such things as reasons, wants, intentions, consciousness and mind against a sustained examination of the use of the relevant words. This is not to champion a mere dealing in words. For, as I have been at pains to illustrate, our uses of language are grounded in action. 'The essence of the language-game is a practical method (a way of acting)—not speculation, not chatter' ([8.8], 421). To examine use is not to do 1950s-style ordinary-language philosophy but something better described as philosophical anthropology. Out of that study there might arise in turn a new branch of inquiry, an empirical but purely descriptive cultural anthropology of language-customs, one developmental or genealogical in approach but purged of mentalistic assumptions. Wittgenstein seems to grant the possibility of such a study when he writes: 'What we are supplying are really remarks on the natural history of human beings; we are not contributing curiosities however, but observations which no one has doubted, but which have escaped remark only because they are always before our eyes' ([8.9], §415).

BIBLIOGRAPHY

For a bibliography of works by and concerning Wittgenstein consult Virgina A. and Stuart S.Shanker, *A Wittgenstein Bibliography,* London: Croom Helm, 1981.

Works by Wittgenstein (in order of composition)

8.1——*Notebooks, 1914–16,* ed. G.H.Von Wright and G.E.M.Anscombe, trans. G.E.M.Anscombe, Oxford: Blackwell, 1961.

8.2——*Tractatus Logico-Philosophicus,* trans. C.K.Ogden, London: Kegan Paul, 1922.

8.3——'Some Remarks on Logical Form', *Proceedings of the Aristotelian Society,* suppl. vol. 9 (1929):162–71.

8.4 *Philosophical Remarks,* ed. Rush Rhees, trans. Raymond Hargreaves and Roger White, Oxford: Blackwell, 1975.

8.5 ——*Philosophical Grammar,* ed. Rush Rhees, trans. Anthony Kenny, Oxford: Blackwell, 1974.

8.6 ——*The Blue and Brown Books,* New York: Harper, 1958.

8.7 ——'Notes for the Philosophical Lecture', in *Philosophical Occasions 1912–51,* ed. James Klagge and Alfred Nordmann, Indianapolis: Hackett, 1993.

8.8 ——'Cause and Effect: Intuitive Awareness', ed. Rush Rhees, trans. Peter Winch, *Philosophia* (Israel) 6 (1976): 409–25.

8.9 ——*Philosophical Investigations,* trans. G.E.M.Anscombe, Oxford: Blackwell, 1958.

8.10 ——*Remarks on the Foundations of Mathematics,* ed. G.H.von Wright, R. Rhees and G.E.M.Anscombe, trans. G.E.M.Anscombe, Cambridge, Mass.: MIT Press, 1978.

8.11 ——*Remarks on the Philosophy of Psychology,* vol. I, ed. G.E.M.Anscombe and G.H.von Wright, trans. G.E.M.Anscombe; vol. II, ed. G.H.von Wright and Heikki Nyman, trans. C.G.Luckhardt and M.A.E.Aue, Chicago: University of Chicago Press, 1980.

8.12 ——*Culture and Value,* ed. G.H.von Wright, trans. Peter Winch, Oxford: Blackwell, 1980.

8.13 ——*On Certainty,* ed. G.E.M.Anscombe and G.H.von Wright, trans. Denis Paul and G.E.M.Anscombe, Oxford: Blackwell, 1969.

8.14 ——*Last Writings on the Philosophy of Psychology,* vol. I, ed. G.H.von Wright and Heikki Nyman, trans. C.G.Luckhardt and M.A.E.Aue, Oxford: Blackwell, 1982.

8.15 ——*Last Writings on the Philosophy of Psychology,* vol. II, ed. G.H.von Wright and Heikki Nyman, trans. C.G.Luckhardt and M.A.E.Aue, Oxford: Blackwell, 1992.

CHAPTER 9
Political philosophy

Arthur Ripstein

For the first half of the twentieth century, political philosophy was shaped by trends in other areas of philosophy. Conceptual analysis and clarification were central, and the philosopher's task was to clarify substantive political argument rather than participate in it. Several other features are worth mentioning: the widespread acceptance of utilitarianism as an adequate account of political morality; the interpretation of and reaction to its rivals, and the rise of pragmatism as an alternative view of philosophy in general and politics in particular. The second half of the century was marked by the rebirth of political philosophy. Justice emerged as the central issue, and debates continue about both its nature and its centrality to political life.

META-ETHICS AND CONCEPTUAL ANALYSIS

The rise of philosophy of language and conceptual analysis set the tone for philosophical inquiry more generally. One consequence of this was that moral and political philosophy focused on meta-ethical issues, such as the nature of moral truth, rather than on substantive questions of political morality. The two dominant positions in meta-ethics made substantive inquiry seem even less promising. Intuitonists insisted that moral truths are as evident as those of mathematics or the deliverances of the senses, and evident to any right-thinking person. Those with persistent perceptual deficits (Prichard used the analogy of colourblindness) were beyond the reach of rational argumentation. Thus there was little for political philosophy to discuss. At the other extreme, emotivists suggested that moral and political discourse was non-cognitive—the expression of feelings and preferences, and the attempt to get others to share them—and thus incapable of rational adjudication (Ayer [9.3]). On either view, such topics as justice or equality were not the sort of things about which respectable philosophers were expected to have theories.

UTILITARIANISM

Despite official philosophical distance from political issues, the dominant outlook in political culture more generally was tied to various versions of utilitarianism, the view that social institutions are to be assessed on the basis of their consequences for promoting human happiness. Utilitarianism was developed in the nineteenth century by Jeremy Bentham (1821 [9.6]) and John Stuart Mill (1864 [9.35]). Its appeal stems from the combination of three ideas: first, that in the end, the only thing that could really matter to political questions was how well or badly people's lives went; second, that in political morality, each person's interests should be counted equally; and third, that difficult moral and political questions admit of rational resolution provided that sufficient information is available. Utilitarianism combines these ideas to evaluate

social institutions on the basis of their consequences for human happiness. Everything from the judiciary and penal institutions, through representative democracy, to trade and tax policy can and should be arranged to provide a framework within which individuals, looking largely to their own advantage, could bring about the best results overall. At least as important as its emphasis on consequences is utilitarianism's unwillingness to allow the appeal to such notions as natural rights.

L.T.Hobhouse's *Liberalism* (1911 [9.24]) exemplified this pattern of political argument. Reforms advocated by Hobhouse that at the time seemed radical have since been adopted in the industrialized world: an active role for the state in education and health, welfare provisions, and redistribution of wealth through progressive income taxes and taxes on inheritance and speculation. Hobhouse's tone is at once confident and tentative. All his policy proposals are offered as experiments about how best to achieve the common good. Although he acknowledges the difficulties of weighing goods against each other (for example, the conscience of a few as opposed to the convenience of the many) Hobhouse sees the only burden of argument to be to establish the empirical claim that the policies he advocates do promote the overall social good. Any other appeal—to abstract rights, especially property rights—he sees as unhelpful obscurantism, unworthy of serious response.

In the 1920s debates about the feasibility of planned economies as opposed to markets also took a utilitarian form. Even Friedrich Hayek (1941 [9.21]), perhaps the most vocal and influential critic of economic and social planning of the time, appealed primarily to the consequences of planning. Hayek argued that large-scale social planning was doomed to failure. Any increase in social planning was sure to hinder individuals carrying out their own plans. Thus he doubted that the state could have any role other than setting up the broad legal framework within which individuals could go about their business. Despite its apparent anti-utilitarian orientation, Hayek's argument actually appealed to the idea that each individual is better situated both to know and to achieve his own welfare than any other agency. Thus, he suggested, the overall consequences of social planning are counter-productive.

MARXISM

The economic downturn and resulting political turmoil of the 1930s created widespread popular interest in Marxism. Like utilitarianism, Marxism developed in the nineteenth century. From the 1840s until his death in 1883, Marx both advocated and predicted worldwide socialist revolution. He saw it as the only solution to the recurrent economic crises that plagued capitalist economies, and as the end to the domination of man by man that he saw throughout human history. Like ancient slavery and feudalism before it, capitalism must give way to a more advanced mode of production. Marx held his socialism to be 'scientific', because it accounted for the development of forms of ownership on the basis of the independent development of human abilities to appropriate nature. Socialism was seen as the inevitable outcome of the tremendous development of productive forces that capitalism had unleashed; an end to material scarcity would bring about collective control of human affairs.

As Marxism gained in popular interest, it drew philosophical attention as well. Many philosophers were sympathetic to Marxism's broad political goals. But the overall thrust of philosophical reflection on Marxism in the 1930s remained deeply critical. Most treatments focused on epistemological issues, particularly the idea of the historical inevitability of socialism. That idea was attacked for being unscientific, for denying the role of human choice in history, and for conceptual confusions about the relation between individual and society. For example, Karl Popper argued that there can be no historical laws, on the grounds that individuals can choose to act contrary to them (Popper [9.43]; Acton [9.1]). Others argued that Marxism's idea of equality was indefensible; still others that Marxism was self-refuting,

because it sought to explain ideas in terms of material conditions of production, thus undermining its own claim to truth.

PRAGMATISM

At the same time, across the Atlantic in the United States, pragmatism was gaining popularity as an account of both philosophy and politics. Pragmatism was part of a broader movement against formalism in American thought. In such diverse areas as law (Llewellyn [9.30]; Cardozo [9.8]) and architecture, themes of experimentation and practice were dominant; ideas of method were down-played. As part of this movement, pragmatist philosophy was deeply suspicious of the sort of conceptual puzzles with which British philosophy was largely occupied.

John Dewey [9.13] was the leader of the pragmatic movement in social and political philosophy. Rather than investigating general relationships among such concepts as the individual, state, property and family, Dewey thought the role of social philosophy must be to 'help men solve concrete problems by supplying them hypotheses to be used and tested in projects of reform' [9.14]. To fix on abstract conceptions, as traditional political philosophy had done, is to help 'clever politicians' to 'cover their designs and make the worse seem the better cause'. Instead, institutions should be 'viewed in their educative effect: —with reference to the type of individuals they foster'.

Dewey also called for the increased democratization of American life. The equalization of wealth and elimination of privilege were offered as goals all Americans could embrace, and the task of philosophy was seen as clearing away inherited philosophical obstacles to the sharing of those goals. What Dewey characterized as 'dualisms' between mind and body, fact and value, and subject and object were to be removed in the hope of making room for a social experiment in which all could flourish. In place of both tradition and any attempt at developing a scientific method, Dewey advocated 'the application of intelligence to solving problems', by which he meant free and open discussion involving as many participants as possible. For Dewey, the only justification democracy needed was showing that it was the most effective way of broadening the pool of intelligence to apply to social problems. Anything less deprives society of the full contribution of all its members. It is central to Dewey's view that there is no general answer to the problems of social life, only particular solutions that are appropriate in response to particular problems as they arise. No general theory about happiness, freedom or justice will help—only democratic discussion of particulars is possible.

Perhaps the most striking feature of political philosophy through the first half of the century was the extent to which it supposed that political argument is not itself a philosophical task. Whether philosophy was seen as confined to conceptual questions, or charged with clearing away obstacles to democratic discussion, few supposed that it had anything to contribute directly to politics. Deep divisions ran through political life, but these were seen as either the results of conceptual confusion or simply false belief. One result was that philosophy was all but silent on what now seem the fundamental questions of politics.

By the 1950s political philosophy looked as though it had lost its subject matter. In the social sciences, the 'end of ideology' was proclaimed (Waxman [9.54]). Piecemeal social engineering in the service of goals that were supposed to be widely shared was to replace impassioned debate over the fundamental terms of social life.

THE SIXTIES

All that changed in the 1960s. The mood of philosophy began to shift, and scruples about addressing large normative topics began to wane. Conceptual analysis lost much of its grip on philosophy, and interest in meta-ethics began to waver. Equally important, were a variety of social changes. The intended audience for academic philosophy grew enormously with the growth of state universities in the United States and 'red-brick' universities in Britain. At the same time, that audience's diversity increased. In 1954, the US Supreme Court ruled that segregation was unconstitutional. In the years that followed, the civil-rights movement demanded that abstract constitutional provision be put into practice. In so doing, it put an end to the idea that only the details of social life needed to be worked out. At the same time, the threat of nuclear war led to increased distrust of governments around the world. The Vietnam War brought both of these issues to a head. Disproportionately many blacks were drafted, and many viewed the war as an imperialist exercise.

One response was another wave of interest in Marxism. Marx's early writings were translated into English in 1960. Rather than historical necessity and economic crises, their central theme was the profound alienation endemic to capitalist society. In addition, Marxist thought had continued to develop in Europe throughout the twentieth century, and came to have an increasing influence. The 'critical theory of society', developed in Germany in the 1920s (Adorno [9.2]; Jay [9.26]) provided much of the vocabulary of student radicals in the 1960s (Marcuse [9.33]). Still, these remained very much marginal positions in the academy.

Many of the dissatisfactions of the period took the form of attacks on liberalism. The criticisms varied, but two were prominent. One charge was that liberalism emphasized individual liberty at an unacceptable cost in equality. The other was that it lacked a coherent political morality, and was little more than the result of a series of shifting political coalitions and compromises. The liberal commitment to the welfare state was seen as nothing more than a reaction to changing political demands.

Utilitarianism was subject to parallel attacks. It was suggested, for example, that the wanton destruction of the Vietnam War had its theoretical basis in the idea that all values are commensurable. If all values can be reduced to a single common scale, then policy-planners could rationally decide to commit atrocities for the sake of their supposed long-term benefits. This argument, popular among both peace activists and scholars, cut deeply against utilitarianism's claim to be a viable philosophy for public justification (Griffin [9.19]; Williams [9.56]; Berlin [9.7]).

RAWLS

It was in this setting that John Rawls's *A Theory of Justice* [9.44] brought new vigour to liberalism, and with it, political philosophy. Rawls seeks to provide an alternative to utilitarianism that will reconcile freedom and equality. The book begins with a bold claim: 'Justice is the first virtue of social institutions', and spells out a conception of justice as fairness. Rawls draws on the social-contract tradition of Locke, Rousseau and Kant to describe a powerful thought experiment. The intuitive idea is simple: suppose you had to choose the basic structure governing your society. To choose, it would help to have information about a variety of things—economics, and human psychology, for example. Now suppose that choice were to be made from behind what Rawls calls 'a veil of ignorance'—you had all the general factual information you could want, but you didn't know who you were, nor what mattered most to you in life. In such circumstances, it would be rational to choose cautiously, so that no matter how badly things went, you would do at least passably well. So, for example, you would never agree to a system that allowed some people to own slaves, for fear that when the veil was lifted, you would turn out to be one of the slaves. Nor would you agree to a state religion, for fear that you turned out to be a member of a persecuted minority.

Nor, for that matter, would you ever adopt utilitarian principles of social organization, for fear that your own most important interests might be sacrificed for the sake of less significant, but more numerous interests of others. Even if some practice, such as slavery, were to have the best consequences overall, no rational person would agree to it if it carried with it the risk of being a slave.

Rawls argues that this sort of reasoning leads to two highly specific principles of justice. The first generalizes freedom of religion, and demands the maximum liberty compatible with the same liberty for others. The second, which Rawls dubs 'the difference principle', calls for the equal distribution of material resources and powers, except when an unequal distribution will benefit those who receive less than an equal share. The first principle is supposed to take priority over the second: liberty can never be sacrificed for material gain.

Rawls deploys the two principles of justice to address a number of further issues including justice between generations, civil disobedience, conscientious objection and moral education. In each case the general thrust is the same: society is to be viewed as what Rawls calls 'a co-operative venture for mutual advantage', in which all share a common fate which is articulated and adjudicated in terms of publicly accepted principles of justice.

In order to get such a determinate result out of such a simple thought experiment, Rawls assumes that the parties in the original position desire certain 'primary goods'—goods that are likely to be useful in pursuit of whatever conception of the good they might have. These include liberty, material resources and what Rawls calls 'the social bases of self respect'. These are the sorts of goods that it is the business of the liberal state to oversee the distribution of. Rawls's point is not that everybody necessarily wants these things, but that by thinking of them as the goods to be distributed, we are able to embrace the idea that individuals are responsible for their ends (hence the importance of liberty) without supposing them to be responsible for their material circumstances (hence the importance of material wealth).

Critics of liberalism had long supposed freedom and equality to sit in an uneasy balance, with no principled relation between them. Rawlsian liberalism offers the two principles of justice in order to interpret the importance of each in terms of the other. Equality gives each an equal claim on primary goods; freedom is important so that each person can use his or her fair share of resources to carry out his or her own life plan. Without equality, though, individual freedom loses its claim. Legitimate shares of material resources set the limits of freedom, because they ensure that one's pursuit of some conception of the good is not imposing unreasonable costs on others.

If Rawls reinvigorates liberalism, it is a liberalism with a difference. Individual political and personal liberties are still central to it. But the emphasis on property and market freedoms characteristic of the traditional liberalism of Locke (or the US Constitution) is gone. For Rawls, property rights are no longer central to the liberal political vision. At best, forms of ownership are to be understood as subservient to equality and personal liberty.

Of course, Rawlsian liberalism leaves many important questions unanswered. How much material inequality is to the advantage of the worst off? How are liberties to be balanced against one another? But if Rawls does not answer these questions, he at least provides a vocabulary in which liberals could address them systematically. The power of that vocabulary is revealed by the extent to which divisive issues have been fruitfully debated in its terms. By making equality central to justice, Rawls provides a way of avoiding fruitless disputes about the relation between freedom and equality, or between fairness and desirable consequences. On Rawls's view, each can only be understood in relation to the others. For example, debates about the legitimacy of affirmative-action programmes (reserving employment or educational opportunities for members of groups that have historically been discriminated against) typically played themselves out as

battles between fairness and desirable consequences. Drawing on Rawls's work, Ronald Dworkin showed how ideas of fairness and merit are always tied up with ideas of social purposes (Dworkin [9.15]).

RAWLS'S CRITICS

Rawls's arguments drew criticism from a wide variety of perspectives. In so doing, they provided the background against which political philosophers could raise their disagreements. Four directions of criticism are particularly noteworthy. One took Rawls to task for failing to consider seriously the distinctness of persons and the importance of property. Another criticized Rawls for not going far enough in the service of equality. A third held that Rawlsian liberalism, with its emphasis on justice, left no room for the moral community that is fundamental to political life. The fourth may well turn out to be most significant in the long run. Drawing on developing feminist scholarship, it points to the way that liberalism fails to take seriously the politics of private life.

Libertarianism

Where Rawls had drawn on the tradition of Rousseau and Kant, Robert Nozick's *Anarchy, State and Utopia* [9.38] sought to reinvigorate the ideas of ownership and individual liberty that were prominent in Locke's political thought. Deeply suspicious of ideas of distributive justice, Nozick argued that 'income tax is on a par with forced labor'. He suggested that the idea of equality is simply a reflection of the envy of those who have less, whether through laziness, stupidity or simple bad luck. In place of concerns about how to create and distribute resources as fairly and effectively as possible, Nozick insists that the important questions about the distribution of goods must all be looked at as questions of entitlement. Entitlements can arise through the acquisition of something initially unowned, through voluntary exchange or gift or as compensation for wrongs suffered. They cannot be acquired in any other way—particularly not on the basis of need or one's comparative share in relation to others.

The root idea of Nozick's view is that liberty must be given priority over any distributive goal. He offers little by way of argument for this claim, apart from some general musings about how each person's life is his or her own to develop or waste, and the suggestion that any alternative to libertarianism would violate the Kantian prohibition on treating others as mere means to ends they do not share. Nozick's development of his position depends much more on the intuitive force of a series of examples.

For example, Nozick invites us to suppose that income was distributed on the basis of whatever distributive principle we think is best. Each person must be entitled to spend their legitimate share however they see fit. Now suppose that one million of these people are each willing to pay a premium of 25 cents to watch their favourite basketball player, Wilt Chamberlain, play. By refusing to play without this premium, Chamberlain thus puts himself in a position to gain an additional quarter-million dollars. This would upset the original distributive pattern. Yet surely each person can dispose of his or her holdings as he or she sees fit. Nozick insists that the example generalizes: liberty would always disrupt any distributive pattern.

Again, in response to the claim that property rights must give way to each person's claim to have a say over those things that effect him or her, Nozick suggests we consider whether the same principles would apply to a woman's choice of suitor—should a rejected suitor get a say in this matter, which plainly affects him deeply? Again, if I am nice enough to lend you something, do you thereby acquire a say over the uses to which I will put it in the future? Nozick suggests not.

Nozick's dependence on intuitive examples lead many to doubt whether much depth lay beneath the book's witty veneer. Thomas Nagel [9.36] describes it as 'libertarianism without foundations'. The

difficulty is that the book's theoretical apparatus is so thin that it is very difficult to know what to make of the examples. For example, it is hard to think of a distributive scheme that is 'patterned' in Nozick's sense. Rawls's difference principle, for example (presumably Nozick's target), specifies the structure within which people can acquire and dispose of goods, rather than a pattern that would require constant interference every time a transfer took place. Thus the example doesn't seem to cut any ice against any position anyone ever actually held. Nozick's other arguments about interference are comparably ambiguous: we might think that a woman's sovereignty over which suitor she accepts is tied to the importance of controlling one's own emotional life, rather than any more general principle that excludes workers from exercising any sort of control over their working conditions.

Nozick's project gains much of its impetus from the idea that people should be able to decide what to do with their lives and with whatever abilities and assets they find themselves with. On the face of it, this is an attractive, even inspiring idea. Yet Nozick is surely confused here. For we cannot take seriously the idea that politics could be a matter of letting people do what they want, *simpliciter*. Indeed, the political philosopher's activity of trying to formulate principled grounds for competing social arrangements gets its point from the need for an articulate account of why some wants count and others do not. In this respect, prohibitions of violence are on a par with limits on election-campaign contributions—all stop people from doing what they might otherwise do. No appeal to freedom, understood as letting people do what they want, can settle these questions. Nor can Nozick claim that people should be left to do as they please so long as they don't harm anyone else. To give content to that claim, he would need some ways of identifying which harms count—something like Rawls's catalogue of primary goods. Otherwise he cannot rule out any state functions, for those seeking state action would be able to argue that they are harmed by not getting their way (Leiberman [9.29]). At bottom, though, Nozick has little to offer to resolve these issues.

Other libertarian projects also sought to pose a challenge to Rawls. Most prominent among these are more radical interpretations of his contractarian apparatus. By modifying the conditions under which the contract might be reached, some sought to derive principles of justice that put more emphasis on property and less on equality. Where Rawls looks to Kant and Nozick to Locke for historical antecedents, Hobbes provides the inspiration for radical contractarianism. In *Morals by Agreement* [9.17], David Gauthier provides the most sophisticated version of this position. Gauthier begins by pointing to the difficulties in appealing to intuitive plausibility in political argument. Intuitions too often reflect past socialization, and they are too easily shifted to do duty in place of arguments. Concerned in part about the problems that plagued Nozick's view, Gauthier seeks instead to ground libertarianism in the theory of rational choice as developed in economics and game theory. The emphasis on rational choice is rooted in the view, widely accepted in both academic and popular culture, that values and standards of evaluation are at bottom rooted in individual preferences. Thus no utilitarian theory of the good, or Rawlsian index of primary goods, can provide a firm basis for justification. Instead, we must look to a well-defined problem of choice: what principles would fully informed rational agents, concerned only to advance their own ends, agree to, *regardless of what those ends turned out to be?* The broad outlines of the story are clear enough. Each would agree to such limits as would protect his or her own choices, and leave him or her free of any obligations to aid others. Various bundles of specific property rights, and methods of dividing the benefits of co-operation have also been suggested (Gauthier [9.17]; Narveson [9.37]).

Radical contractarians have doubtless produced some of the most elegant contributions to political philosophy. Yet their mathematical accounts tend to be so idealized that it is very difficult to see how they are supposed to make contact with actual people pursuing their own diverse ends. Worse, many of the simplifying assumptions required to make their formal apparatus yield determinate conclusions seem to beg important political questions. If the model of rational choice is supposed to describe actual human

behaviour, then it seems to be compatible with the wide variety of different institutional arrangements that have resulted from human interaction. For they too are the product of individuals pursuing their diverse ends. To get the highly specific results of Gauthier's contract, and a unique solution to the problem of rational agreement, the agents making the agreement must be idealized. But if they are, it becomes difficult to see how the radical contractarian project is any less dependent upon intuitive plausibility than are competing views. (Ripstein [9.45])

Analytical Marxism

Perhaps the most interesting criticisms of libertarianism come from a group that describes itself as 'analytical Marxists'. Where libertarians argue that liberalism sacrifices liberty for the sake of equality, analytical Marxists suggest that liberalism pays insufficient heed to equality. As a group, they are highly selective of what they take from Marx's thought (Elster [9.16]; Roemer [9.47]). Their work is of interest here because of its use of the same conceptual tools and vocabulary as liberal and even libertarian thought. Where an earlier generation of Marxists was suspicious of such tools as 'bourgeois', today they are embraced as neutral and effective. This has helped to make it clear that technical tools cannot decide between political ideals; at best they can make the presuppositions and commitments of competing views more nearly explicit (Roemer [9.46]; Cohen [9.10], [9.9]).

Communitarianism

A third line of criticism of Rawlsian liberalism also takes aim at libertarianism. Both are charged with a destructive obsession with individual rights, and an indifference to the importance of community both to making political life fulfilling, and to providing the context within which normative claims could be made and discussed.

The communitarian argument has taken a variety of forms. In *Liberalism and the Limits of Justice* [9.49], Michael Sandel focused on Rawls's view, and argued that both Rawls's argument and the politics of liberalism more generally reflect a number of indefensible metaphysical assumptions. Each of the parties behind Rawls's veil of ignorance chooses without knowing his or her own conception of the good. Sandel suggests that this hardly qualifies as a choice at all. First of all, the parties are given a sharply defined problem of choice and an algorithm for its rational solution; their agreement is more like the agreement of a number of students on the solution to a mathematical problem than an agreement between a number of people about how to regulate their affairs. But for Sandel, there is a deeper problem lurking here as well. By choosing in the absence of any shared conception of the good, Rawls's contractors are making shallow choices, devoid of moral significance. Only choices made in light of one's view about what is most important in life will fully engage one's moral capacities. Yet Sandel maintains that a liberal society cannot allow such choices to inform political life. Because of its official neutrality on questions of the good life, a liberal society can at best appeal to neutral procedures all can accept, rather than speak with a common voice that all can recognize as their own. As a result, it has trouble asking for the sort of sacrifices that political life requires. Instead, any sacrifice it demands will be seen as made for someone else's good. For example, Rawls's second principle of justice requires those with marketable abilities to accept less than they might for the sake of those with less. They may make the requisite sacrifices, but they do so out of compromise rather than principle. Sandel insists that this is the fate of contemporary liberal democracies: interest groups compete to control the apparatus of government with no common vision of the good life to limit their pursuit of their interests.

In *After Virtue: A Study in Moral Theory* [9.31], Alasdair MacIntyre sets his sights wider, arguing that the liberalisms of both Rawls and Nozick are nothing more than the dying gasps of a moral culture in decline. MacIntyre suggests that the vocabulary of rights on which both rely lacks the only sort of background against which it could have a coherent use. Nozick's difficulties in explaining the rights he focuses on is merely a special case of a more general cultural trend, in which talk about rights becomes nothing more than an emphatic way of insisting on some claim. MacIntyre fears that, however inadequate as an account of the meaning of moral language the emotivist metaethics of the first part of the century might have been, it is very close to the truth about the use of moral language in the latter part. Without strong ties of community and tradition, moral language becomes just another species of rhetoric, influencing behaviour rather than providing reasons.

MacIntyre sees the failure of liberalism as a special case of a more general failure of the enlightenment project of providing a universalistic grounding for morality and politics. The theme is not a new one. In the 1940s, Michael Oakeshott had attacked what he characterized as 'rationalism in politics', the view that human reason has the power to solve all social problems (Oakshott [9.39]). MacIntyre focuses on the related, though distinct idea of universality. He argues that the idea of universality misses the significance of particular commitments in making us the people we are. The enlightenment project of providing a universal standpoint, able to evaluate particular cultures and practices from outside, was a failure. It missed the way in which an on-going way of life provides the cultural space within which people can regard their particular social roles as appropriate. So long as we demand a justification from outside our practices, we are bound to end in disappointment.

For MacIntyre, tradition is important to giving sense to moral discussion because it gives concrete content to the idea of sharing a common fate. Moral thinking and discussion is essentially interpretive. Traditions provide the raw material for interpretation, without which political argument deteriorates into nothing more than veiled bargaining.

While Sandel is silent about what specific conception of the good would be appropriate to any contemporary society, MacIntyre is more specific on this score. He suggests that the appropriate ethical outlook is to be found in the traditions of Christianity, especially Roman Catholicism. The final chapter of *After Virtue* suggests that the only two moral options left open to us are the piety of St Benedict and the nihilism of Nietzsche.

Other communitarians have made parallel points. In *Habits of the Heart* a group of social scientists sought to document the debasement of the moral vocabulary that MacIntyre pointed to; they found that the subjects they interviewed often felt alienated from society and their moral relationships (Bellah *et al.* [9.5]). They also found that they had difficulty in articulating the moral standpoint that they spoke from.

The communitarian criticisms of liberalism are difficult to assess, in part because the criticisms are posed at so many different levels. For example, Sandel argues that Rawls ends up with a shallow view of politics because he begins with bad metaphysics. And so he misses 'The good we can know in common that we cannot know alone'. But Sandel doesn't tell us what that good is. And it is difficult to see how he could: because he focuses on metaphysical issues, it is not clear whether or how his arguments are supposed to issue in any particular politics. At another level, he is clear about the need for community, rather than a mere association of isolated individuals. But, as Will Kymlicka has pointed out, he never explains why the state should be the proper place in which that sense of community is to be fostered. Why not in secondary associations, like churches, unions, clubs and neighbourhoods? if these are the *loci* of community, the state may need to change in ways that nurture those communities. But that is very different from acting as a primary community itself (Kymlicka [9.27]; Guttman [9.20]).

Still, communitarians are sensitive to something important that is missing from liberalism. Liberalism sees no need for the state to be a community, except in the thinnest sense of something to identify with, and a common forum of justification. But there is a lingering question of whether a liberal state can provide even this much. For the emphasis on private pursuit of the good life (even where this includes secondary associations) may not foster the commitment to the state required in order to make the sacrifices it demands. Often those sacrifices benefit those to whom one is related only as a fellow citizen. Charles Taylor argues that the liberal state cannot make any plausible claims about mutual advantage, because each individual's contribution makes little difference to the long-term survival of the state. So it seems to rely instead on moral high-mindedness, and the claims of justice. It is not clear that this is enough to call forth sacrifices from citizens (Taylor [9.52]). Still, if Taylor is right in his diagnosis of the problem, it is difficult to see how a communitarian state that emphasizes its common traditions and way of life can do any better at sustaining itself in a world in which individuals have lives of their own. All the communitarians' favoured examples of successful communities—democratic Athens, eighteenth-century Geneva—excluded large portions of their populaces from political participation, and identified political participation with the good life (Herzog [9.23]). MacIntyre gives slightly different examples, but they involve groups that share a conception of the good for religious reasons. Yet their treatment of dissenters was unacceptable, and it is hard to imagine how such a model could be generalized to a society that is religiously divided. Unless some way is found to include everyone in political life, so that it is the most central of each person's identity-conferring life project, the same problem will just recur. Most people will be unwilling to make sacrifices, unless they take them to be demanded by justice.

FEMINISM

Liberalism, libertarianism, Marxism and communitarianism have all been questioned in recent feminist criticism. Liberalism and libertarianism have been attacked because of the way they have focused on voluntary relations between adults of roughly equal power without antecedent ties, at the expense of the more pervasive relations of dependence and domination that characterize relations between parents and children, or women and men. While communitarians have focused more on relationships involving antecedent ties, they have attached too much weight to the founding of communities and their traditions. As a result, they have failed to acknowledge the ways in which virtually all communities have oppressed women and excluded them from public life. Marxists, in turn, have been criticized for focusing on production and ignoring reproduction (Pateman and Shanley [9.42]; Sunstein [9.51]; Jaggar [9.25]).

At one level, feminists can be thought of as occupying various positions along the previous political spectrum. There are conservative feminists, liberal feminists and socialist feminists. Which has the legitimate claim to the name 'feminist' is itself a contested question within feminism. But to focus on those differences is to miss the originality and intellectual power of feminism as a philosophical position.

Feminism is a comparatively new social movement. Where Rawls and Nozick can carry on a debate by developing positions already articulated by Kant or Locke, many feminists are uneasy about helping themselves too readily to the arguments and outlooks of philosophers who, whatever other disagreements they may have had, verged on unanimity in their relegation of women to second-class status. From Plato through the middle ages, women were thought of as imperfect realizations of the ideal male form; from the seventeenth through the nineteenth centuries, they were seen as a different kind of thing, subject to feeling rather than reason, and incapable of participating in public life. One strategy for working within the traditional mould is to simply ignore its overt sexism, and look instead to the universal roles that particular

thinkers have described, and try to find a way to enable women to participate more fully in those social roles. Susan Moller Okin has dubbed this strategy 'add women and stir' and many feminists join her in rejecting it, on the grounds that it takes for granted that the position of men within sexist societies is the appropriate goal for women to aspire to (Okin [9.40]; [9.41]).

Feminist research has drawn attention to a variety of ways in which traditional debates about politics have overlooked important power relations and injustices. Of particular significance are the division between public and private life and the assumption that the family is a realm beyond justice. Feminists have also been critical of the assumption that male experience provides the appropriate lens though which social relations in general, and the status of women in particular, ought to be viewed.

Public and private

Modern political thinkers have drawn a division between a public sphere in which decisions are made and carried out, and the private sphere within which individuals pursue their own private ends. For Nozick (to use an extreme example) the public is exhausted by its role of mutual protection and enforcement of property rights; everything else is private, the domain of individual contract and consent, in which the public has no say or legitimate interest. In Rawls, the public enjoys a more expansive role, ensuring fair shares of resources and guaranteeing equality of opportunity. Communitarians draw the line between public and private differently, supposing that its contours depend on the shared practices of an on-going way of life. They also tend to attach more significance to the public; where liberals and libertarians see the private as the realm of freedom, communitarians suppose freedom has its proper place in participation in collective control over public life. But they share the emphasis on that division.

Feminists have recently challenged these divisions. The reasons for the challenge become clear if we focus on the place of family in relation to the distinction. Is the family private or public? Traditionally, both in political philosophy and in legal decisions, the answer has seemed obvious: it is private. Important constitutional decisions in the United States have been made on the basis of the family's right to privacy. Rawls seeks to determine the appropriate rate of savings in a just society by asking us to suppose that the contractors in the original position are 'heads of households'. None of the prominent political philosophers we've looked at even considers questions of social responsibility for the rearing of children. And despite the obvious inequalities of status and power that are to be found within the traditional family, these too seem to fall outside the scope of justice, and to be viewed instead as private arrangements between individuals.

Feminists note two striking features of these omissions. One is that political philosophy, which aspires to study 'the first virtue of social institutions', is silent on so many aspects of social life. The other is that the very features about which it is silent are those traditionally involving women.

One response has been to suppose that the distinction between public and private must simply be eliminated, since it has plainly been both unreflectively drawn and harmful. Another approach has sought to keep the distinction while re-drawing its boundaries. Preserving a private sphere, free from state interference is important, especially for those who find themselves outside the mainstream of public culture, such as lesbians and gay men. Feminist arguments in favour of reproductive rights also draw on the legitimacy of a private sphere. But if a private sphere remains, it cannot be organized around the prior boundaries of the domestic sphere. Inequalities within the family, whether in household tasks, access to resources or the threat of physical violence, all admit of assessment in terms of justice. Pornography, long considered a private matter by liberals, can be viewed instead as a matter of creating and reinforcing the conditions of the oppression of women.

Feminist critiques of pornography provide a clear example of questioning the division between public and private. The argument has two components; the first is the claim that pornography is harmful to women, and so ought not to be thought of as protected expression. The second, deeper strand, questions the traditional liberal understanding of the role and nature of political expression. In *On Liberty,* John Stuart Mill [9.34] defended free expression on the grounds that it is necessary to encourage the search for truth and to make room for a responsible, because informed, citizenry. Recent feminist scholarship has suggested that this view misunderstands the nature of expression in general, and pornography in particular. Pornography does not make claims to truth that might be examined on the basis of their merits; instead, it constructs social roles in which individuals have no choice but to live. Catherine MacKinnon [9.32] points out that nobody would take pornography's implicit claims about the role and availability of women seriously if they were made explicit. But that is not how pornography works.

The critique of traditional divisions between public and private enters again here: where liberal thought views pornography as something that is enjoyed in private, feminists look at it as an essentially public activity, because of its role in shaping social roles. The suggestion is that one does not view pornography (or live in a society in which pornography is widely consumed) without coming to think of women in a very specific way.

This emphasis on the political nature of the split between the public and the private also explains feminism's characteristic attitude towards traditional philosophy's claim to universality. By identifying what it is to be truly human with participation in the public life of markets and politics, and interaction with equals, traditional philosophy relegated many of the activities women have been involved into a secondary status. The past several decades have seen increasing numbers of women entering the workforce. Yet incomes and opportunities for advancement have been structured in ways that disadvantage women. They have typically been tied to the model of a breadwinner who has a wife at home capable of taking care of his needs, and of preparing him to work another day, both through feeding him and by providing an emotional respite from the pressures of the working world. These practical issues have a philosophical dimension, because such concepts as procedural fairness, merit, freedom and equality of opportunity have been understood in terms of unexamined assumptions about private life.

Other strands in feminism pose different challenges to traditional political philosophy. The primacy of justice has been challenged, on the grounds that relationships involving dependence, such as the care of children or the elderly, cannot be assimilated to questions of justice. But rather than supposing that these fall outside the scope of political philosophy, or can be treated as simply different, some feminists have argued that relations of care and nurture should be thought of as primary, and relations of justice derivative. This emphasis on non-contractual relationships has led to proposals for a radical re-thinking of such concepts as autonomy (Baier [9.4]; Gilligan [9.18]; Held [9.22]; Ruddick [9.48]). Still other feminist scholarship has urged the rethinking of the political implications of such concepts as embodiment and power, in directions very different from those pursued by the mainstream of English-speaking political philosophy (Scott [9.50]).

One other recent development in political philosophy deserves mention: the renewed interest in radical democracy. Dewey's influence dwindled for decades, but many of the themes he emphasized are again the focus of debate. Part of the reason is continuous with feminist concerns about illusory models of universality and the need to hear voices that had been excluded. Representative democracy made many of the same promises of universality as did classical liberal theory; both arguably failed to take seriously the claims of those who did not readily fit into their models of normal life. The institutions of representative democracies have been organized around assumptions about typical needs and demands. As the electoral franchise has been extended this century, increasing numbers of people have acquired the legal right to

vote, yet many have no further concern with politics than voting in periodic elections. Ordinary citizens—especially, but by no means exclusively, women and members of minorities—have been excluded from having an effective political voice in the democracies. The project of radical democracy is to re-think democratic institutions in a way that makes room for full participation by all. Like Dewey, radical democrats emphasize participation both for its benefits to those involved and for its promise of solving problems.

Much of the impetus for democratic theory has come from outside the English-speaking world, but its influence continues to grow. One major force has been the Brazilian social theorist Roberto Unger. Unger first came to prominence as a communitarian critic of liberalism; his *Knowledge and Politics* [9.53] argued that liberalism rested on an indefensible metaphysics and psychology, and on moral scepticism. His more recent work has abandoned communitarianism in favour of what he calls 'superliberalism', the idea that 'the basic terms of social life' should be permanently up for grabs, all institutions subject to subversion from below.

The politics of radical democracy are represented by the 'Rainbow coalition' in American politics. Made up of women's groups, members of more traditional leftist movements, people of colour, environmentalists and parts of the peace movement, it has been defined (so far) more by a sense of making common cause in the face of perceived exclusion than by concrete political proposals. Philosophically, it shares with the Deweyan pragmatism of the 1930s a commitment to eliminating privilege and an insistence that making institutions more open and participatory will thereby also make them more effective (Laclau and Mouffe [9.28]; Cohen and Rogers [9.11]; Cunningham [9.12]; Young [9.57]). Radical democracy also shares Dewey's suspicions of such philosophical buttresses of traditional politics as the dualisms of reason and imagination, or reason and passion. The vocabulary in which the rejections are phrased has changed, but their upshot has not. Abandoning such dualisms carries with it some risks. Allowing every social context to be overturned may strike many liberals as a recipe for disaster. Pragmatist or radical democrat, the response to this worry is the same: no amount of philosophy will keep the barbarians from the gate—only an involved and reflective public can. In the end, their deepest commitment is to replacing philosophy with politics.

CHAPTER 10
Feminist philosophy[1]

Sarah Lucia Hoagland and Marilyn Frye

Feminism re-emerged in the turmoil of the 1960s in anger and resistance, committed to revolution, to change. Heralding this wave and following nineteenth-century themes, Simone de Beauvoir wrote in 1947: 'One is not born, but rather becomes, a woman.' There is a difference between being anatomically female and becoming what society recognizes as a woman: while there are facts, they take on meanings only within a social context. What we are as women we become, formed by oppression, being defined in relation to men as Other, different.

The women's liberation movement went on to name western society, whether in Europe, Scandinavia, Australia/New Zealand, Great Britain or America—South, Central and North, as male-dominated: men define and legislate women's place in society. The stereotypical concept of women as helpmates or temptresses (of man) and as feminine (passive, emotional, dependent, not-masculine) defines woman only in relation to man. This man-made concept of woman, falsely presented as women's nature by theories of biological or psychological difference, both legitimizes and conceals individual and institutional violence of men against women, and locks out any positive conception of female power, collective or individual female resistance, or female bonding. Feminists protest the violence, the erasure and the imposition of definition.

Unlike most other systems of oppression and exploitation, the oppression of women is hard to perceive because its mechanisms include extensive mind-binding discourse—a multi-layered and inconsistent mythology which women internalize in the process of learning their native language, being schooled, being inducted into religious practice and community, and being on the receiving end of marketing, advertising, commerce and entertainment. Much about the circumstances of women in male-dominated societies promotes confusion, befuddlement and false consciousness: for example, the mythology of love, the sexual double standard, the division of life into public and private (Firestone; Atkinson; in R.Morgan; in Gornick and Moran; in Koedt; Daly). Consigning women to realms of privacy, intimacy and mundane processes of maintenance, and to mind-numbing personal service, as well as clerical and factory work, encourages a microscopic apolitical mode of experience—close-up, fragmented, non-systematic perceptions and interpretations of our worlds.

Feminists began promoting consciousness-raising groups in which women talked with each other about their personal lives. Discussing subjects such as sex, work, marriage, motherhood, childhood experiences, sex roles and health led to recognizing how women's lives are laced with sexism. (In R.Morgan; in Gornick and Moran; in Koedt.) Consciousness-raising (CR) is a means of appropriating our experience, previously suffered as apolitical dailiness, and reading off it and through it the patterns of social power. CR is a strategy for people whose first critical task of liberation is to clearly perceive the problem. (Hartsock.)

Patterns of social power are made difficult to perceive in a variety of ways. Global patterns are played out differently in different women's lives. For example, the masculine myth of women as dangerous may be

etched in different ethnic and racial communities on one woman's life as 'temptress', on another's as 'castrator'. And the pattern of male access to women's bodies is played out on some women through required exposure of their bodies, on others through required concealment, veiling. The practical contradictions of double binds make it difficult to perceive the political meanings of our actions. For example, a woman may brilliantly defend women's rights, but her engagement in the debate aligns her with the *status quo* sexist value that makes women's but not men's rights debatable. Patterns of power are also obscured by semantic voids and historical erasure, and by our being censored or manipulated into silence. Middle-class white women, finding their seamless lives intolerable, faced a 'problem with no name' and began defining it (Friedan). Black women, addressing their erasure as women and as blacks, recovered their herstory of agency and resis-tance (Shange; Parker; Wallace; in Hull; Lorde). Lesbians, realizing the censoring of our lives, proclaimed our love for women (Wittig; in Birkby; Johnston; in Myron and Bunch; in Penelope and Wolfe; in Beck; in Ramos). And progressive white men, finding their place at centre stage threatened, guilt-tripped white women by claiming that addressing women's issues was racist because it diverted attention from the struggle against racism…a claim often welcomed by black men who had been challenged by black women for making them 'the slave of a slave' (in Cade).

As feminists overcome these barriers to perception, we find connections between apparently disparate and contradictory phenomena. For example some US politicians attacking abortion favour forced sterilization of poor women and women of colour; and while professing concern with the fetus in the womb they do not support the child outside. Feminists began realizing that the consistent pattern suffusing these contrary manifestations was one of institutional control of women's bodies and control of women's biologically and socially reproductive (socializing, care-taking) labour. Patterns of systematically related barriers functioning in the dominant group's interest serve to maintain male domination, police class divisions and ensure white supremacy (Frye).

Feminist theory is a collective process that appeals to, is based in and is mediated by experiences which variously situated women name and appropriate in CR as authoritative grounds for action and thought. All this work involves a fascinating and intricate dance between experience and theory: while experience remains the checkpoint, analyses affect the meanings of our experiences and enlarge their scope. The process engages us in struggles both among feminists and with others which, though sometimes painful, fan the flames of our imaginations.

Feminists expanded the concept of politics to include sexual politics—power relations between men and women as individuals but especially as classes (Millett). Following themes of suffrage, some feminists took up the call for equal rights in order to bring the republic into conformity with its ideology as a democratic society. They argue that sex differences do not justify civil discrimination and insist on women getting equal opportunity, benefits and protection under the law. This liberal-feminist demand has exposed the subordination of women as necessary to the social contract among privileged men. While the patriarchal state may have ended in Europe for men with the overthrow of the monarchies, it did not end for women: the social contract between men includes the division of society into public and private spheres, establishing men's political right over women and their access to and use of women's bodies and labour in the private sphere. (Pateman.)

Other feminists point out that demanding equality with men paradoxically endorses men's status as the norm or paradigm of humanity and citizenship. Furthermore it actually cedes this status not just to any men or all men, but to privileged men (middle to or upper-class, able-bodied, heterosexual, Christian, white), and thus validates the structures and stratifications of western liberal industrial capitalism. This system grew on colonialism, genocide and slavery; it works by extraction of 'surplus value' from the labour of workers. Worker exploitation is facilitated by assigning women to lower status and pay and maintaining an

unacknowledged substratum of women's unpaid labour in the 'private' sphere of home, subsistence production and child-care. This requires the subordination in various ways of women of all races and places; even women of aristocratic and owning classes often play a role in domestic and social management of acknowledged economic value to privileged men. The system also requires that privileged males control the reproduction of a population of suitable workers and consumers, which they do in part by regulating women's sexuality, fertility and child-rearing. (Eisenstein; Hartsock; Ferguson.) Capitalism is a system of stratification, inequality, exploitation, oppression. It is neither structurally possible, nor morally defensible, for all women to have the rights and privileges such a system gives those at the top. For the oppression of women to end, there must be entirely different structures.

Many feminists have noted that male violence against women transcends the material or economic requirements of capitalism; it appears to maintain male dominance as an end in itself. They argue that there is a declared war on women manifest in assault and murder, rape, child sexual abuse, sexual harassment, medical abuse, etc. Some feminists argue that rape is a terrorist institution (Card), benefiting all men because it keeps women believing they need men for protection (Griffin; Brownmiller). Others focus on the misogyny that suffuses men's entertainment, and argue that pornography eroticizes rape and abuse, solidifying the connection between sex and violence characteristic of masculinist life (MacKinnon). Others note that pornographic sons hold the same contempt for the body as church fathers against whom they rebelled (Griffin). Expressing this contempt, pornography is necrophilic and emphasizes sensations without feelings, promotes the mind/body split, and robs women of erotic desire as a source of knowledge and a kind of power (Lorde). Resisting woman-hating agendas that divide women against ourselves, some feminists reach for the dis-covery/creation of woman's Self capable of sisterhood and integrity (Daly; Dworkin; R.Morgan).

Many feminists see female heterosexuality not as a biological given but as a social construct made to seem natural. Central to the systematic oppression of women, the institution of heterosexuality supports dualistic, hierarchical conceptions of difference which underlie other structures such as racism (Daly; Frye; Wittig). Feminists have argued that the institution of female heterosexuality is necessary to the traffic in women which constitutes patriarchal kinship and mediates men's personal and economic relations (Rubin in Reiter; Sedgwick). Some argue that it secures individual women's unpaid services to individual men essential to the structures of domination (capitalism, colonialism, etc.). Some say the institution is grounded in men's very definition of 'woman': 'woman' is defined as what turns men on, as (hetero)sexual availability on men's terms (MacKinnon), as 'appropriated by man'. By these definitions lesbians are not women: not 'women' to men sexually, but also economically, politically and socially (Wittig). Others note that female heterosexuality works politically to separate women from each other, inhibiting our solidarity and our bonding in resistance. Instituted female heterosexuality, presented as natural, renders lesbian experience invisible, or if visible, aberrant and abhorrent. Some note the erasure of lesbian existence even in the women's movement and academic feminist scholarship (Rich). Suggesting a lesbian continuum (Rich; in B.Smith; Card), some have emphasized the wide range of woman-bonding (in marriage-resistance, nunneries, lesbian connection, etc.) and look to female friendship as a model both of ethics and resistance (Raymond). Some argue that it is only friendship, intimate connection, and not mere commitment to political principles, that adequately supports women's solidarity across barriers of race and class (Lugones and Spelman in Pearsall; Anzaldúa; Hoagland).

Focusing on still another material reality of women's situation, racism, women of colour have continuously challenged white feminists. Arguing that black feminism has distinct origins, theorists articulate the interrelatedness and simultaneity of oppressions (in B.Smith; Moraga). Naming a different history of economic participation, domination by white women, and 'freedom' from the dubious privileges of

femininity, feminists argue that black women face distinct problems in resisting capitalist male domination, and have distinct cultural sources of resistance (in B.Smith; A.Davis; Lorde; Kingston). Feminists decry finding themselves in someone else's discourse or story, trapped either in a picture that distorts their lives because of hidden cultural assumptions, or in silence because they have ceased to try to fit into the dominant context (Lugones and Spelman in Pearsall). Noting the relation of ignorance to acts of ignoring (Frye), feminists began articulating privileges that some women enjoy in patriarchy which permit them to distort, co-opt and exclude the concerns of other, less privileged women. Arguing that race and class differences must not be simply tolerated, feminists show they provide the 'fund of necessary polarities between which our creativity can spark like a dialectic' (Lorde). Thus feminists analyse the importance of theories of women of colour moving from margin to centre (hooks).

Some feminists focus on separating from men and from masculine discourse as a way of undermining heterosexual patterns and male parasitism, of becoming woman-identified (Radicalesbians in R. Morgan). Total power is unconditional access, and the first act of shifting power involves taking control of male access to women (Frye). Further, some say that when white feminists argue that women must work with men, they in effect align themselves with white men, their connections with women of colour being at best distant and lacking the revolutionary intimacy of friendship. Thus their analyses are too simple, failing to acknowledge both the differences in the situations of women of colour and the possible fruits of alliance (Lee in Hoagland and Penelope). In not reaching towards women of colour, they acquiesce for example in black men's assuming the right to define black culture. Others argue that separatism is a lens through which we perceive the world and is the prism for many of our ethical choices, focusing our attention on matters central to lesbians and other women (Anderson in *Signs,* 19.2). As such, separatism is a form of engagement. Actually most feminists engage in separating in one way or another from patriarchal values—humanism, masculine notions of rationality, gender roles, individualism, for example—in the effort to free up feminist imagination from defensive focus on men's agendas and to construct new values in new frameworks.

As feminist philosophy moves on, each achievement of clarity reveals more complexity. One early problem and all its variations has yielded a central contribution of feminist philosophy: explorations of how women are agents while neither fully in control of our situation nor total victims—how we are both subjects (agents) and subjected (de Lauretis). Actually the related questions of agency and subjectivity inform, explicitly or implicitly, most feminist philosophy.

A good portion of feminist theory starts from understanding ourselves as victims and therefore as unlike the free-willed, self-defined Man of dominant western philosophy. Prior to feminist activism, rape, wife-beating, incest and sexual harassment were all regarded as private and personal matters, a woman's fault and, contradictorily, a matter of boys being boys. Much feminist work involves articulating ways men victimize and then blame women. However, by the mid 1970s, feminists noted that we must avoid both blaming the victim *and* victimism—the perception of a woman as only a victim and not also a resister. (Barry.) In fact, perceiving women only as victims fails to acknowledge that women *act* in patriarchy. There are many ways both of resisting male domination and of collaborating, and this must be acknowledged to fully understand women's situations and agency. Even direct coercion standardly involves arranging circumstances and options and then depending upon the victim to choose the least bad option available. We are agents, but not free agents, when we choose intercourse over lifethreatening bodily harm. (Frye.) We collaborate when we hold men to lower standards as colleagues, friends and lovers than we hold women to. On the other hand, many feminine stereotypes, as is true of slave stereotypes, obscure resistance to domination, for example acts of sabotage are interpreted as incompetence or insanity (Hoagland).

Perceiving women only as victims also keeps us from realizing how women participate in other oppressive structures, for example ways white women in feminist organizations ignore African-American or Latina women, ways middle-class women use middle-class standards against working-class women, ways heterosexual women silence lesbians, ways able-bodied lesbians ignore disabled women's needs, ways Christian-cultured women (white, black or Latina) foster Christian values uncongenial to Jewish and Native American women, ways middle-aged women champion ageist values when perceiving old women and discount the young. (In Moraga and Anzaldúa; in Anzaldúa; in B.Smith; Macdonald in Macdonald and Rich; in Bunch and Myron.)

An historic example shows how tricky this gets. In one of the early US works dealing cross-culturally with disciplinary inscriptions of power on the body, Mary Daly investigated forms of men's torture of women: European witch-burning, Chinese foot-binding, Indian suttee, African genital mutilation and American gynaecology. By researching men's agendas she shows, for example, that the history of gynaecology is a continuation of the history of the contest over women's bodies. Audre Lorde, however, points out that Daly explored all these atrocities but provided only European images of resistance, and thus does disservice to women of other cultures by erasure of the fact that they have constructed means of resistance within their own traditions. How would Chinese women, for example, be recognized beyond the victim status (Chow in Mohanty)? Even active engagement in resistance does not ensure that we are not also participating in oppression.

Women's agency, ability to act, is compromised overtly by men's violence and imposed barriers to movement, and covertly by masculinist conceptions of female virtue and the self. Early feminist work on morality involves naming the immorality of masculine political agendas and demanding rights, such as the right to control our bodies. Other work challenges socially prescribed feminine virtues such as nurturance and volunteerism, and argues that the standards of womanhood involve self-sacrifice to a degree that is immoral. (In R.Morgan; in Gornick and Moran.)

Some have noted that in masculine discourse the traits defining women's goodness mark them as morally deficient, and have undertaken to revalue stereotypical feminine traits. For example women's 'weak ego boundaries' actually indicate the capacity of empathy, women's 'deference' is actually sensitivity to the needs of others. (Gilligan.) Others question the revaluing of feminine 'virtues'. Nurturing has not cured the violence in women's lives; a woman's misplaced gratitude towards men for taking less than full advantage may be mistaken for care, and misplaced gratitude is a form of moral damage. Women have developed these skills and capacities to survive under patriarchal domination; it does not mean they are timeless virtues. (Card.)

Nevertheless, responding to the fractured view of ethical relations produced by a focus on rights and justice and duty, many feminists reach for an ethics of care (Held; Noddings; Manning; Tronto). Such an ethics more accurately addresses relationships among people than does the fiction of the masculine ethical agent, one who is autonomous, aggressive and competitive (i.e. socially inept), for example the contractual man of liberal utilitarian theory. This model is inadequate to the majority of social arrangements. For example the mother/child relationship is neither voluntary nor contractual. An ethics that uses the model of a mother acknowledges dependency and sharing in relationships. (Held.) Further an ethics that involves not a stance of impartiality (ignoring institutionalized social oppressions) but a stance of partiality (within which one can empathize with the individuals involved) reveals a ground from which different sorts of solutions to moral problems become apparent (Friedman).

All thought arises out of social practice, and maternal practice is governed by concern for the preservation, growth and acceptability of children. It arises out of practices oppressive to women and children and can involve inauthenticity, so it needs a feminist analysis. Nevertheless, maternal practices can

give rise to distinctive ways of conceptualizing, ordering and valuing which can found a feminist peace politics capable of exposing flaws in masculinist militaristic thinking and masculine conceptions of peace (Ruddick). Other feminists question the ideology of heterosexual virtue by which women are held to be better than men because allegedly nurturant and non-violent. Noting this ideology ignores the material history of nurturance (women give freely, expect nothing in return, and are responsible for righting the destruction of men's actions without appropriate power and resources), they argue this framework obliterates women who reject these values and women who actively resist men's appropriation of women's labour (Allen).

Other feminists note that dominant western conceptions of womanhood have excluded black women from the definition of woman and femininity (A.Davis; Cannon; Carby). Some argue that many women do not have the relationship to motherhood that is romanticized in patriarchal images. The cult of womanhood as applied to the southern plantation mistress glorified a wifehood and motherhood and was denied to black women slaves: white men's control over white women yielded heirs and citizens, their control over black women yielded property and capital. (Carby) Consequently some concepts that apply to white women don't apply to black women. For example, self-sacrifice is not a *moral* imperative for those consigned to sacrifice in a state of slavery (Cannon). Others argue distinctive values emerge from women of colour's motherwork, namely survival, identity and empowerment. Simply contrasting an ethics of care with an ethics of justice may bypass survival values as in effect pre-moral. Questions of survival are central and cannot be taken for granted; black mothers resist oppressive ideology both in terms of their own capacity to mother and their children's ability to develop a meaningful racial identity. (Collins.)

Some question the rejection of a justice ethic. An ethics that leaves starving strangers outside the realm of moral consideration, as a care ethic seems to do, is inadequate, especially when we have had a hand in creating those conditions and/or benefit from them (Card). Others note the care ethic's inadequacy in addressing those outside the caregiver's circle, and they question the opposition between justice and care (Friedman; Okin; Young). In developing a feminist concept of justice, they continue challenging the impartial masculine moralist, arguing for a body politic that articulates rather than homogenizes difference (Young).

Significantly, resistance often emerges from neither the care nor the justice frameworks (in Anzaldúa). On the one hand, if we were to focus on women's choices in resisting rape, we might find values emerging that are different than those associated with the care ethic (Moody-Adams in Card). On the other hand, some address questions of survival and resistance, arguing that the moral sphere of black women is survival against tyrannical systems of oppression. Moral agency, thus, involves developing virtues under these circumstances. The virtue of feistiness allows black people to resist white agendas. Unctuousness, acting sincere with the insincere, can help women create possibilities where none existed before. While drawing on notions of care, theorists nevertheless contextualize it with an ethics of survival and resistance that derives from the lives of black women during 250 years of slavery and 100 years of segregation. The emerging moral wisdom involves not only how to survive but how to prevail with integrity. (Cannon)

Central to moral agency under oppression is realizing one is neither in total control nor a total victim: it is not because we are free and moral agents that we are able to make moral choices; rather, by making choices, acting within limits, we declare ourselves to be moral beings. Some suggest the function of lesbian ethics is the development of lesbian integrity, agency and community, and that rather than value autonomy and regard ourselves as related to others antagonistically as occurs under patriarchal ethics whose function is social control, we value autokoenony—self in community. Thus we regard ourselves as one among many, realizing our possibilities emerge only in community and across communities. (Hoagland.)

Revolutionary interacting across communities involves playful world-travel. This is not men's idea of play: to conquer and kill, to colonize and demoralize; one must not play with conquerors. Worldtravel instead involves flexibility, playfulness and epistemic uncertainty. (Lugones) Here we encounter the trickster who unsettles our solidity, seriousness, our ignorance, our arrogance (Cameron). The trickster and play (which can be life-threatening, but then ignorance is life-threatening) become ethical options to disciplinarian notions of duty and justice, dismantling the dismissing power of privilege and erasing the dominant power of ignorance. Here also we become each others' resources, learning about ourselves and each other by travelling to each others' worlds. World-travel offers passage from the constraints of any one culture's ethical construction and is essential to realizing the liberatory potential of feminist thought. (Lugones.)

The theme of women-as-agents transposes, in the realm of epistemology and philosophy of science, to the theme of women-as-knowers. Feminists have consistently attended to the matter of who the scientist or knower is; they have not accepted the abstraction of knowledge from the knowers. They indict the 'impartial' knower much as they do the 'impartial' moralist.

Current feminist challenges to science, following nineteenth-century feminist criticisms, began by exposing the sexist bias of (male) scientists. For example, at a time when scientists thought the frontal lobe was the centre of thought, men did studies 'proving' women's frontal lobes were slightly smaller than men's. When upper- and middle-class women were wearing torturous corsets, their tendencies to fainting were cited by men as 'proof' of their frailty. Some feminists argue that the construction of the masculine *rational* and *orderly* stands on the grave of the feminine *passionate* and *unruly,* and they challenge the whole endeavour for its fractured construction (Griffin). Related feminist queries challenge the laboratory construction of knowledge which extracts pieces from nature, and wonder at the knowledge thereby lost (Merchant; Keller). Still others question the research methods meant to obtain objectivity, questioning the sort of knowledge that is thereby constructed (in Tuana).

Contrasting the earlier nature-as-organism metaphor with the nature-as-mechanism metaphor underlying modern science, feminists argue that the rise of science as an ideology of (male) control over (female) nature results in wilful disregard for and exploitation of the planet and thereby in ecological disasters. Exposing sexual and sexist metaphors scientists use, they argue that sexual politics structures the nature of the scientific empirical method which pretends to be free of cultural and political assumptions. Scientists also inject values into their descriptions of the facts to be investigated. Sexism is intrinsic to scientific discourse. (Merchant; Keller; Irigaray in Tuana) Many feminists explore the use of scientific authority and ideology to keep women 'in their place'—economically dependent and intellectually deprived.

Others focus on the elitism and classism of the professional endeavour—the gate-keeping that ensures that science is a preserve of privileged men. They trace the theft of knowledge/practice from women and the suppression of knowledgeable women, for example the outlawing of midwives during the rise of gynaecology. They demand the reclamation of science, both of empirical, common-sense knowledge (knowledge, for example possessed by European witches about herbs) and of sophisticated technologies, for the service and benefit of the people who are not to be the passive consumers of the mysteries of the elite. And they argue that the professionalization of science, together with the ideology of progress, develops knowledge which primarily benefits only certain classes. (Ehrenreich and English.)

Feminists have exposed some spectacularly bad science which promotes sexism and sexist agendas (Bleier). Arguing about whether the practice of science is intrinsically sexist and racist or whether sexism and racism distort a science which is intrinsically a sound practice, they agree nonetheless that science is not value-neutral (Harding). Some think feminism can bring science more in line with its own goals, exposing the wilful ignorances of a self-selected group of male thinkers. Others argue that the goals

themselves are hopelessly mired in the depths of masculine imagination. A collage of contributions to the understanding of science emerge out of these critical discussions. Many feminists set about recovering women's contributions to science, women whose work has been used by men who receive awards. Others continue to expose the sexist and racist underpinnings of scientific work. Others develop feminist methodology and epistemology or theory of knowledge.

The science upheld as paradigm and most prestigious and, not accidentally, the science most male-identified and 'hardest', is physics. Feminists challenge the assumption that physics is paradigm on the grounds that (1) the subject matter of physics is not complex; (2) physics provides descriptive formulas which are not explanations, and explanations which are vague metaphors, e.g. 'Big Bang' and 'Black hole'; (3) it excludes intentional, learned and 'irrational' behaviour. Reality is complex; science should explain; and the phenomena of intelligent animals have as much right to a high place on the agenda as sub-atomic particles. (Harding.) Standard conceptions of science take the visual knowing of an inanimate object as the paradigm of knowing. Developing a theme of interdependency, some feminists suggest, instead, knowing a person as the paradigm (Code). The latter involves knowing something massively complex; in knowing persons we constantly provide ourselves with explanations; and such knowledge is interactive. Conceiving the knower or researcher as non-interactive enables 'him' to remain transparent. The ideal of scientist as a neutral, objective, irrelative observer allows particular political agendas *(status quo)* to go unquestioned (as is the case with the impartial moralist), promotes knowledge as an instrument of domination and silences his objects of study, his subjects. Acknowledging and inviting interaction between knower and known casts the knower as an interactive agent in the world.

Pursuing the question of bias in science and knowledge, some feminists have articulated various versions of a 'standpoint' theory (Hartsock; Frye; Gilligan; Collins; Harding). The core theme of 'standpoint theories' is that knowers differently located in history and social structures have access to different knowledge of both the social and non-social worlds. For example, men's studies of lions, invoking king-of the-jungle mythology, portray males as dominant. Actually, however, lions are socially expendable, unable to join together in mutual co-operation and protection; 'lion' prides centre on the activities of adult lionesses (Reed). In this and other studies of animal behaviour women observers have discovered very different things than are recorded by men observers (Haraway). In situations where immediate observations are unlikely to differ so dramatically, research agendas and design are affected by the locations and interests of the inquirers. At the very least this means a complete science would require contributions from many locations. Furthermore different lives may also generate quite different, even non-communicating, conceptual frames, values and meanings, so the different knowledges may not be readily assimilable into a collective unified knowledge of a unitary world.

Many feminists also suggest there are different concepts of rationality. Masculine rationality is constructed by excluding attributes and experiences of women and the underclasses. Some pursue the observation that a rational (coercive) unity that appeals to 'truth' doesn't necessarily move people to action; there is no evidence that appeals to reason, knowledge or truth are uniquely effective. Political action and change involve many capacities besides reason including capacities for empathy, anger and disgust. (Flax.)

Feminist rethinking of the knower has also led to the suggestion that individuals' knowing is derivative of community knowing. In a sense the primary knower is a community: what counts as evidence is communal, and construction and acquisition of knowledge are communal processes (Nelson).

Some feminists have questioned the feminist preoccupation with epistemology understood as matters of relations among knowledge, knowers and truth. The interesting relations include those among knowledge, desire, fantasy, passion and various kinds of power (Daly; Flax; Jaggar). The claim that feminist revisions will increase the objectivity and truth of science may be an attempt to make feminism innocent when what we

want is power. When we don't pay attention to desire and fantasy and power, we more easily make epistemology a site of retreat from the conflicts and complexities of interpersonal and political issues (Flax). For example, when privileged white feminists' own projects of knowledge are criticized by other women, women of colour and/or less privileged, as harmful to them, the response often has been not to attend to the women who are being harmed but to attend to theoretical questions about knowledge and theory (Lugones).

Partly as a result of these sorts of considerations, feminists began to realize that the concept of standpoint is not sufficiently complex. It tends to be about fixed locations in a reified 'world'; in the background is an image of two people standing on opposite sides of a statue seeing different things, where one observer is the Husband and the other is the Wife. A much more complex concept was developed, 'situated knowledges' (Haraway). It adds to that background picture, acknowledging differences in allegiances among observers (for example, they may be members of cultures which are in conflict), and places the observers in three-way conversations with the statue which is now animate and talks back. Some ecofeminists have perhaps been most insistent on some version of the world as an active subject (Griffin; Adams; in Gaard; in *Hypatia,* 6.1; in Warren) and on making room for the world's independent sense of humour (Bigwood). We can acknowledge the trickster, 'give up mastery but search for fidelity, knowing all the while we will be hoodwinked' (Haraway).

One reason for a feminist emphasis on epistemology in relation to the project of exploring women's agency has been to rescue women from men's 'knowledge'/construction of women. Feminists focusing on psychology note how it constructs the female (Weisstein in R.Morgan). For example, mental health for a woman is defined by psychiatrists as her being feminine, heterosexual and sexually accessible to therapists (Chesler), and the adult standard replicates the male standard while the female standard is quite different. Early challenges to psychology note the circularity of psychoanalysis: women who deny being phallically oriented in fantasy or reality merely 'prove' that orientation by their denials, women who report incest merely 'affirm' theories of rape fantasy, etc. Feminists expose the theory that women fantasize rape as a male professional cover-up for the sins of the fathers (Rush).

Others challenge concepts such as hysteria and frigidity, while also suggesting one investigate instances of testeria (the ability to calmly, efficiently and maturely carry out assaults, torture and genocide, and planetary disaster such as war, capitalism, totalitarianism) (in R. Morgan; in Gornick and Moran; Loesch in Kramarae and Treichler). Feminists note the types of behaviour for which one is most often hospitalized are disturbingly correlated with race, caste and sex (in Gornick and Moran; in R.Morgan). Others note that psychology, including some feminist psychology, interprets political phenomena as personal problems and pathologies, reversing the feminist-activist discovery that the personal is political (Kitzinger and Perkins). One feminist 'take' on psychoanalysis interprets it as an unwittingly revealing description of patriarchal society and the damage done to individuals as they are inducted into it (Mitchell; Rubin in Reiter).

Focusing on men's relationship to power and the effect material life has on consciousness, some argue that because of the way women are responsible for rearing children in nuclear families in western industrial societies, the infant's first intimacy is solely with a person who is female and socially subordinate. The process of identity formation, thus, is different for boys and girls. This suggests that in such societies men's propensity towards separation and aggression and women's propensity for connection and community result from the sexual division of labour in child-rearing. The social organizing of parenting produces women more capable of non-hostile relations but it also perpetuates patriarchy through the reproduction of mothers. (Chodorow; Hartsock)

In the western patriarchal tradition 'the knower' is unitary, that is, all knowers are in principle the same—the rational man. Feminists introduced plurality and complexity, recognizing many knowers with different knowledges, first with the revolutionary addition of women as knowers and the exploration of differences between women and men as knowers and agents. But the concept of the self, male or female, as having unity and stability is also challenged. A feminist picture emerges of the partial autonomy of a world of desire and fantasy, suggesting that the subject is a shifting and always changing intersection of complex, contradictory and unfinished processes (Flax). The unitary self exists only through the practice of domination, and can sustain its unity only by repressing other parts of its own and others' subjectivity (Flax; Lugones). Particularly in the work of women of colour, we find that plural subjectivities are fluid rather than solid, and contextual rather than universal (Lugones; Anzaldúa).

Challenging the phallic appropriation of meaning and knowledge, refusing to enter the male symbolic by leaving females' sex as negative or unnamed, some feminists undertake to construct a positive female difference that is elusive, fluid and ambiguous (Irigaray), wild, chaotic and disorderly (Daly). By giving voice to that which has been repressed in the canon of philosophy, feminists force canon-mongers to abandon their pretence of neutrality and reveal themselves as gendered, indeed sexed.

Far from being neutral, the ideally rational moralist, scientist and citizen of the liberal state constructs and unifies himself by splitting off aspects of the self he associates with the lives of the disenfranchised, and he thereby commits himself to the logic of paranoia (Scheman). He is threatened by the always already impending accusations from abused women (Nye). The resulting problems of modern philosophy (mind/body, reference and truth, other minds, scepticism) are the neuroses of privilege and are unsolvable so long as the subject's identity is constituted by those estrangements (Scheman; Bordo). Post-modern masculine renditions of the mind/body split are no less abstract, metaphysical, psychotic, misogynistic (Brodribb).

White identity is similarly dependent on marginalization of difference (Spellman): only by defining women and the East as peripheral can western man/humanism present itself as central (Spivak). Much of the theory of oppression in the earlier phases of feminist philosophy concerned oppression by the most privileged people, whose locations of oppression were the most simple (namely privileged white males). Feminist theories of the nature and mechanism of oppression have been made more complex and nuanced since attention has shifted to the ways oppression is enacted by people in mixed positions, like for instance that of white women in western societies or class-privileged women in other societies, and how oppression is experienced by other women who might desire sisterhood and alliance with them.

When western feminists write about Third World women, making assumptions about women's oppression which are rooted in western experience, western feminists become the only true subjects of the counter-history. This contributes to the colonization or erasure of Third World women, robbing them of their history and political agency. (Mohanty; Chow in Mohanty.) When white feminists construct the category of woman as unitary and universal, they replicate patriarchal pseudo-neutrality—this time a cultural or racial neutrality. They achieve the unity by infusing the notion of woman with their own cultural experience and meanings, splitting off and marginalizing women of other cultures. This ethno-centring enables white western women to write about Third World women in ways that impose white western women's meanings and agendas and which erase Third World women's history, agency *and* perceptions of white western women. Western feminists can learn from Third World women they study that the latters' access to the political and sexual scene is autonomous and authoritative. There must be simultaneous questions: 'Who is the other woman? How am I naming her? How does she name me?' (Spivak.) Who am I to her?

Feminist projects involve progressive revisions of our understanding of ourselves as we dialogue with each other, discover problems in earlier theory, and explore new ways of appropriating our experiences and enlarging their scopes through consciousness-raising, playful world-travelling and theory-making. We focus

on divergent aspects of our subjectivity emerging from our experiences as variously situated selves, and in the process offer and find varied contributions to creating/ dis-covering feminist resistance and revolutionary constructions of female agency.

Simone de Beauvoir argued that women must come to full consciousness by antagonistically opposing men as men have opposed women and each other, making Others of men. Many feminists have rejected both de Beauvoir's individualism and this vision of liberation, but it does provide a picture of the fate that befalls you if you decide resistance is enough: you end up in the masculine world of selves busily trying to annihilate each other. Feminists have emphasized the urgency of creating for women (and other oppressed folk) alternatives to a life or self defined only by resistance to and assimilation to male orders of law and language. More significantly, many argue that enduring alternatives cannot be created, like camp-sites for campers, by some women for all women. They have to be continuously created through the creation of selves in community—identities independent of the oppressors and their agendas that do not await validation or legitimation by dominating individuals or institutions (Daly; hooks).

Though much of de Beauvoir has been rejected, many of her themes endure: the theme that selves are continuously created; the idea that making of selves is mortally risky and requires existential courage; the recognition that if you fail to create yourself you will collapse into someone else's creation; the idea that in creating one's self (selves) one is creating value. Feminists variously characterize such selves as wild, radical, creative, feisty, plural, lesbian, self-critical, fiery. The continuous creation and instability of the female selves is also emphasized by many theorists (Daly; Anzaldúa; Lugones). Consciousness is never fixed because discourses change, because historical and material conditions change, because the relationships with others through which identity which is negotiated change; because we are alive. Subjectivity, thus, is not a fixed point of departure or arrival but an on-going construction, (de Lauretis.) The difficulty of women's self-construction leads some feminists to focus on rehabilitating genuine passions such as anger and lust (Daly; Lorde; Parker), some to focus on respect (Addelson; Card), and some to focus on the prerequisites of the integrity necessary to resist coercion, manipulation and de-moralization (Cannon; Hoagland).

The idea that making female selves is mortally risky and requires great courage is perhaps most vividly expressed in the work of some mestiza women (women who cross borders, women of mixed race) (Anzaldúa; Lugones). Leaving behind the familiar, predictable, boundaries and frames within which female and racialized selves have been constructed, giving up the hope of integrity in a prefabricated identity, there is the possibility of being nothing—going someplace unimaginable and not finding yourself upon arrival. Removing masks: the possibility that there is no one at the core (in Anzaldúa). It is a creative project of freedom to recognize one's varied selves in different contexts, to recognize one's self deprived of agency but retaining imagination, to recognize the self oppressed as another face of the self resisting, to grasp that an intention formed by the self you are in one place cannot be carried out by the self in another, and still recognize yourself (Lugones; Anzaldúa).

Mestiza plurality/multiplicity is distinct from the multiplicity of those who develop multiple personalities as a creative survival technique in the face of severe childhood trauma and/or abuse. Mestiza plurality is often characterized as plural modes of being which are available and evolving in plural or ambiguous external situations. While there is no uniform experience of multiple personality, its multiple modes flow in relation to present external situations, as well as according to logics of past situations no longer externally real, and logics internal to the structure of multiple selves. These experiences wreak havoc with the whole constellation of concepts related to *self:* unified self, core personality, choice, authenticity/inauthenticity, conscious/unconscious, memory, epistemic community, co-operation, consensus, difference, community, 'I'. (Leighton.)

The human possibility of multiple personality, as distinct from the plurality of a sort exemplified by the mestiza, reveals that there is more to self and subjectivity and their formation by violence and domination than feminists have yet understood. What can become a problem for people with multiple personalities is not multiplicity but amnesia and sabotage and what is required is not sterile singularity but memory, hobnobbing and solidarity—which suggests that multiple personality may be the useful analogue of communities created under oppression. (Card; Cuomo in Card; Leighton.) Having unavoidable and intimate acquaintance with simultaneous multiple perspectives, some multiples can verify most decisively that there are different ways of simultaneously thinking and feeling with integrity about one and the same thing—something feminists resisting patriarchal science, ethics and politics may need verified repeatedly (Leighton).

Mestiza consciousness also provides for new understanding. It models a tolerance for ambiguity, a transgression of rigid boundaries, of borders set up by dominant groups to distinguish 'us' from 'them'. (Anzaldúa.) It is a consciousness that lives on the borders—lives in neither place and both. Mestiza consciousness raises questions and suggests new thinking about locatedness and its relation to identity.

Mestiza consciousness, unlike a unitary patriarchal consciousness that preserves itself by insisting on seriousness and a unitary world, can show to all feminists the possibility of playful world-travelling which undermines the seriousness fertilizing tyranny and indicates how liberatory possibilities only emerge in community with others. When we travel to another's world, we see what it is to be them in their world. And we see ourselves as we are constructed in their world. (Lugones.) By travelling to each other's worlds, we gain knowledge we need to change, we begin to unravel some of the mind-binding of professional masculine authority, and we thereby begin to dismantle dominant ideology. We are each other's sources of knowledge.

World-travellers engage in conversations, moving the centre around. If they never did before, they begin to speak for themselves, they recognize in others what was hidden in themselves, they speak to their sisters, resisting the gaze of conquerors. If they ever did before, they cease trying to speak for the other, cease trying to exercise an imperialist moral gaze, cease trying to be in charge; instead they listen in a way that finds the other speaking back to challenge not only their understanding of her but their understanding of themselves. They see and are seen in her life. And they locate themselves in the histories of women.

Feminist philosophers generally reject any biological determinism according to which the oppression of women might be explained or justified as a natural consequence of anatomical configurations and functions of male and female human bodies (de Beauvoir; Daly; Wittig; Butler). Perhaps as a result of the desire to avoid any hint of such biological determinism, a good deal of feminist philosophy neglects the female 'sexedness' of our bodies, leaving it unremarked and not integrated in the theories, except in connection with critiquing or revaluing motherhood. But some feminists are very concerned with female bodies, sensual pleasures, physical eroticism and sexuality, independently of their connection with reproduction (Irigaray; Frye; Wittig; J.Allen; Spivak; Zita; Bartky). It is suggested that a fundamental process of the oppression of women is the suppression, indeed annihilation of autonomous female sexuality—eroticism intrinsically related neither to male/men/masculinity, nor to reproduction, and this is connected by many feminists with the erasure of autonomous female selves or subjectivities and with the enormity and riskiness of the projects of selfconstruction (Irigaray; Cixous; Daly; J.Allen; Spivak).

The suppression of autonomous female eroticism is vividly enacted in the erasure of the lesbian alternative, or its co-optation in pornography, and many feminists have argued that making lesbian eroticism a real and practical option for all women is an essential part of liberation strategy (Hoagland; Frye; Card; J.Allen; Trebilcott; Wittig; Wittig and Zeig).

Some claim that the feminist focus on reproductive freedom or the patriarchal appropriation of the womb—especially the tendency to make this the defining issue of feminism—is a mistake and mistakenly buys

into the image of woman as mother. Prior to coupling and maternity, cross-culturally and transhistorically, is physical, symbolic and/or psychological clitoridectomy. The suppression of the clitoris is presupposed by patriarchy and family. It may well be that the patriarchal suppression and feminist reinstatement of clitoral (independent of men and non-reproductive) sexuality constitutes an intersection of cultures and simultaneously an intersection of body and identity at which the immense variety of women and our needs, perceptions, creations and theories can communicate and be articulated. (Spivak.)

Each feminist effort gives us yet another aspect of our possibilities. There is truth in all of them. The political discussion and the process of constructing female selves and agency is multivocal (Lugones). Many feminists argue that only plural subjects can invent ways to struggle against domination that will not merely recreate it, and that subjectivities can be imagined whose desires for plurality impel them towards liberatory action (Lugones; Flax).

Wild Women (Daly). Willful Virgins (Frye). Womanists (A. Walker). Lesbians. Amazons. Home girls (in B.Smith). Witches. Spinsters. Las Mestizas (Anzaldúa). Crones (Macdonald in Macdonald and Rich; B.Walker). Lovhers (Brossard). Sorceresses. Woman warriors (Kingston). *Les guérillères:*

> There was a time when you were not a slave, remember that. You walked alone, full of laughter, you bathed bare-bellied. You say you have lost all recollection of it, remember…. You say there are not words to describe this time, you say it does not exist. But remember. Make an effort to remember. Or, failing that, invent.
>
> (Monique Wittig)

NOTE

1 In feminist philosophy there is such a rich ferment of ideas and so many women tumbling over each other in discussing them, that it is formidable, if not impossible, to attribute origination of these ideas to any individual. Key ideas have often emerged nearly simultaneously in several authors' work, and ideas expressed most influentially in a particular text may have originated elsewhere, in particular, among feminist activists and artists engaged in political activity and struggle. Further, it is misleading to attribute a view to a person which she held five years ago, but not now, thereby encapsulating her thought and denying the incredible vitality of the field. The movement of these ideas is not a history of individuals. Thus we avoid forms which attribute ideas to one person while nevertheless naming some who were there and in whose work you can find this material. Further, we are not trying to be textually faithful to particular writings in characterizing positions; we are blending the accounts of several feminists in the ideas we explore. Our work exhibits a North American slant, particularly in the forms disputes over difference have taken, because that is our location of feminist activism and philosophizing. Finally, virtually no claim here ascribed to 'feminists' or 'some feminists' should be assumed to be shared by all feminists; none should be taken to serve as the criterial test of who or what counts as 'feminist'.

A note on reference style: authors referred to are named in the Bibliography and cited in parentheses in the text (inside the sentence punctuation when the scope of the reference is just one sentence, and outside the sentence punctuation when the scope is more than one sentence). If just a name is given, the reference is to that author's book(s). If a name is preceeded by 'in', the reference is to an anthology edited by that woman. If a reference has the form 'Smith in Jones', the reference is to one or more articles by Smith in an anthology edited by Jones.

CHAPTER 11
Philosophy of law

Calvin G.Normore

The past forty years have seen a remarkable interpenetration of law and philosophy. Philosophical treatises like J.Rawls's *A Theory of Justice* (1971) have been studied with as much care by lawyers as philosophers while philosophically sophisticated works of legal theory like H.L.A.Hart and Tony Honoré's *Causation in the Law* (1959) have had an influence in areas of philosophy with no obvious connection to law. So deeply connected have the two subjects become that it is probably not possible any longer to say where the philosophy of law leaves off and the rest of philosophy or the rest of law begins. This essay discusses recent work in the areas usually treated as central in books and courses in the philosophy of law—fundamental jurisprudence, the theory of crime and punishment, and issues in responsibility and tort.

FUNDAMENTAL JURISPRUDENCE

Contemporary work in Anglo-American jurisprudence starts from H.L.A.Hart's *The Concept of Law* (1961). In that book Hart argues for a sophisticated legal positivism which finds the source of legal authority in the acceptance by a community of a system of rules. That system is grounded in a fundamental rule of recognition which determines what is to be included among the rules which are the ordinary laws ([11.9], 97 ff.) This picture has two essential aspects. First there is the role of acceptance. Unlike natural-law theories Hart's finds a crucial aspect of the binding force of law in its acceptance by a community as binding. Second there is the notion of a rule. Unlike earlier positivist theories, notably that of John Austin which focused on the idea that a law was a command (typically a threat) issued by a sovereign and backed by force, Hart's theory claims that laws are rules which serve as standards for guiding conduct. Deviations from these standards may well be punished and many people may be motivated to conform merely by the fear of such punishment but theirs is not the point of view from which these are standards and give rise to obligations. That point of view, rather, takes the law as a guide for behaviour and holds the fact that something is a law to be a reason for following it. Those who find or make themselves outsiders to the law may nonetheless act in accord with the law (out of fear of sanction or a desire not to stand out for example) but they do not follow it. Hart illustrates the difference between the two points of view by reflection on the difference between a typical attitude to the law— which is taken to obligate and is used as a guide to action —and to the threats of a gunman—which may oblige us but do not obligate us and with which we would not comply if we did not fear the consequences of non-compliance ([11.9], 80 ff.) Hart recognizes that a system of rules for guiding conduct could exist without officials of any kind but thinks that such a system will have obvious defects which can be overcome by supplementing the primary conduct-guiding rules with secondary rules governing the recognition, change and enforcement of the primary rules. A fully developed legal system will consist of rules of both kinds.

I began by describing Hart's position as sophisticated legal positivism and it is certainly the case that he distinguishes sharply between moral and legal obligation and refuses to ground either in the other. Nonetheless he recognizes an intimate connection between them which is itself grounded in what he takes to be the fact that both are systems of rules closely connected with human survival. For him this fact ensures that there will be a minimal content 'naturally' present in any plausible legal or moral system. Thus while he denies that the immorality of a rule automatically excludes it from the law he recognizes that some features of law are natural in the sense of being a part of any well-established legal system governing the behaviour of human beings in a world like our own. Prohibitions like 'Thou shall not kill' and structural features like the attachment of sanctions to prohibitions are examples to which he points.

Hart's picture of the law opened new and wide avenues of communication between legal theory and philosophy. His conception of rules, of rule-following and of the relations among systems of rules was closely connected with ideas worked out by Wittgenstein and J.L. Austin and forcefully advocated by writers like P.Winch. His insistence on the need for thought about how the law could be normative connected him both with those writers and with others who were concerned with how norms could be part of a philosophy which took modern science seriously.

What distinguishes Hart most sharply from traditional positivist theories of law is his recognition that law has a normative aspect which cannot be reduced to anything like predictions or threats. The law 'claims' that we ought to obey it. What distinguishes him most sharply from traditional natural-law theorists is his insistence that the norms involved in the law are specifically legal norms which arise in the acceptance of a legal system by a community.

How norms could emerge from the combination of the existence of a practice and its acceptance has come to be seen as one of the deepest problems of contemporary philosophy. The problem's significance for legal theory was already recognized by H.Kelsen who in his *General Theory of Law and the State* (1961) arrived at the remarkable view that every legal system rests on a single norm (roughly of the form 'the laws of this system ought to be obeyed') which is presupposed in the operation of that legal system and in legal (as contrasted with sociological) study of that system. In effect Kelsen took the normativity of the law to be presupposed by the law. Hart's view, on the other hand, was that law was indeed normative but was nonetheless entirely constituted by the existence and acceptance of certain practices. Since to accept a rule is at least to treat it as a reason for action, it is not implausible that one's own acceptance of a legal system gives one reason to follow it but why the acceptance of such a system within your community should give you reason to follow it whether or not you accept it yourself is considerably more mysterious. In consequence at least one of the most notable of Hart's students, Joseph Raz, has been driven, in *The Authority of Law* (1979), to acknowledge that there is no general obligation to obey the law (in the sense of 'obligation' in which being under an obligation entails having a reason to act).

Contemporary jurisprudence is dominated by responses to Hart. Perhaps the most influential has been that by Ronald Dworkin. In a series of papers collected in *Taking Rights Seriously* (1977) Dworkin challenges key aspects of Hart's picture. First he argues that Hart has overemphasized the role of rules at law. Dworkin contrasts rules with what he calls 'principles'. They differ in that when a rule clearly applies to a case it dictates how the case is to be treated. Rules may conflict but such conflicts must be resolved by deciding which rule is to apply. Rules may be vague but such vagueness is resolved by deciding whether the rule applies. Hart had suggested that when such decisions are themselves not dictated by other rules a judge who makes them is simply legislating. Since conflict and vagueness seem inescapable in the law Hart thus recognized a realm of judicial discretion practically indistinguishable from legislation. Principles on the other hand have 'weight' for Dworkin. In *A Matter of Principle* (1985) he develops his earlier argument that different principles may clearly apply to a situation and may point in different directions. In such a case the

decision should take all of them into account. Principles are (or provide) reasons for action and like reasons can conflict, override and be overridden, and serve as guides to the interpretation of statute and of precedent cases.

Having argued for the category of principles Dworkin applies it in two striking ways. He uses it first to provide a new model of adjudication and second to argue for a very close relation between law and morality.

Dworkin illustrates his model of adjudication through the figure of Hercules, a judge who knows every statute and every case and suffers no limitations of memory or cognitive capacity. Dworkin suggests that what Hercules must do to settle a case before him is to come up with a theory of the law as a whole and apply it. To generate such a theory of the law Hercules will treat precedent cases and existing statutes as data and will be guided by his current stock of principles. His aim is a theory which accounts for as much of the data as possible and gives each principle the range and weight which seems appropriate. In constructing such a theory Hercules may be led to the view that there are implicit in the law principles not previously noticed. To construct a sufficiently general and coherent theory he may also be forced to conclude that some earlier cases (those which he cannot fit into a satisfactory theory) were wrongly decided. Once he has such a global legal theory Hercules will apply it to the case before him. This case then serves as a further data point. Dworkin suggests that in a well-developed legal system there will be enough cases, statutes and already recognized principles to make the construction of such a global theory possible. Thus he thinks it at least very unlikely that judicial discretion in Hart's sense is ever called for.

In his magisterial *Law's Empire* (1986) Dworkin re-phrased the project in which Hercules is engaged as a project of providing an interpretation of the law by analogy to the way in which a director might interpret a play by Shakespeare. Dworkin regards the project of interpreting as a project of discovering the intention behind something —even in those cases in which we cannot suppose that what is being interpreted is a product of anyone's actual intention. Thus we can interpret a social practice (Dworkin's example is the practice of doffing one's cap in the presence of certain others) by treating it 'as if it were the product of a decision to pursue one set of themes or visions or purposes, one "point" rather than another' ([11.7], 58–9). This move illuminates Dworkin's project but it also makes it more controversial because, by appealing to the concept of interpretation and to literary and dramatic examples of its use, Dworkin opens jurisprudence up to the debates about interpretation which have raged among literary critics and philosophers of literary criticism for much of this century. This has had the sociological effect of giving literary critics employment in law schools and the theoretical effect of embroiling legal theory in the debates around deconstruction.

In *Law's Empire* and his more recent papers Dworkin develops his account of how cases, statutes, rules, principles and other elements are to be interpreted around the slogan 'Law as Integrity'. The integrity of the law is a matter of its internal coherence and the systematic application of its fundamental principles. To conceive of the law as having integrity involves first taking it to be an ideal of political practice that legislators try to make the law morally and politically coherent and second taking there to be a requirement on the part of judges to try to interpret the law as morally and politically coherent. Dworkin takes this demand for coherence to be of one piece with the requirement that the law be just and both substantively and procedurally fair. He argues that interpretive practice of judges must attempt to treat the law as though it flowed from principles of justice, fairness and procedural due process. This has the consequence of placing a theory of political practice (a rather hopeful liberal theory of political practice) at the heart of the theory of adjudication. Not surprisingly this has been highly controversial.

Dworkin argues for a much closer relation between law and morality than Hart admits. He claims, for example, that the Constitution of the United States of America appeals directly to moral principles and moral rights which thus become part of the law and have a legal weight which must be respected in deciding cases. He argues that fundamental moral values, fairness for example, have legal force and can be used both

to determine what the law is and how it is to be applied. He has argued that in situations where it seems to a citizen that a statute violates a moral right for whose legal standing a substantial case can be made the citizen is under no obligation to obey the statute and that the state should take special care with such cases of civil disobedience and should be very reluctant to prosecute them.

Dworkin's relationship to the natural-law tradition is complex and subtle. His accounts of the legal force of moral principles and rights are put forward as claims about the best interpretation of the actual constitutional and legal systems of the North American and European democracies. He denies that what is to be properly called 'law' in any society at any time must respect even the fundamental aspects of morality as we conceive it—or even as that society at that time conceives it. He rejects, for example, the thought that Nazi law was not law at all. Nevertheless he also suggests that 'law' is what a Wittgensteinian might call a 'family-resemblance' concept and that Nazi law differs *as law* in significant ways from Anglo-American law —ways which might make it incapable of justifying coercion. He seems thus committed to the possibility that there might be valid law which did not provide anyone with a reason for acting.

Whether or not we count Dworkin as a natural-law theorist there has been a revival of natural-law theory in the work of philosophers and jurisprudents like Alan Donagan, John Finnis and Germain Grisez. At the centre of this movement has been Finnis's book *Natural Law and Natural Rights* (1980). Finnis begins with the claim that law is necessary for the provision of certain goods which are essential to human flourishing. Among those goods he counts life and health, knowledge, play, aesthetic experience, friendship and other forms of sociability, practical rationality and the contact with the larger order of things which he calls religion. Finnis claims that, properly understood, this is an exhaustive list and that the goods on it are each basic in the sense of being neither reducible to the others nor ranked with respect to them. They are incommensurable requirements for full human flourishing. What Finnis calls the 'common good' of a community is a complex of all these goods and their derivatives in the particular forms appropriate to the members of that community. It is, thus, itself very complex. Finnis reasons from this fact and from his reflections on the nature of the good of practical rationality itself to the conclusion that authority is necessary. Nor is authority necessary only to deal with those who put their own interests ahead of the common good. Even in a community of those striving to attain the common good there would be need for authoritative solutions to co-ordination problems. Such solutions can be found in custom, but, because custom is such an unwieldy instrument, are more likely to be provided by rulers and the legal systems they create. For Finnis the authority of a particular legal system is parasitic upon the fact that most of the community does in fact conform to the demands that legal system makes. This fact and the need for some legal system legitimize *(ceteris paribus)* the particular system in place. There is thus provided a reason for conforming to the demands of that legal system.

Whereas Dworkin conceives of law as an instrument of justice and Finnis conceives of it as an instrument of goodness, Richard Posner and the 'Law and Economies' movement of which he is a central figure conceive of it as an instrument of economic efficiency.

The Law and Economics movement began from Ronald H. Coase's paper 'The Problem of Social Cost' (1960). It received impetus through Guido Calabresi's analysis of the fault system in his *The Costs of Accidents* (1970 [11.30]) and through the analysis of entitlements in G.Calabresi and A.D.Melamed's 'Property Rules, Liability Rules and Inalienability: One View of the Cathedral' (1972 [11.31]). It achieved the status of a movement after the publication of Richard Posner's *Economic Analysis of Law* (1973). Posner agues that the basic aim of law is to alter incentives. For example the law deters activity by raising the expected costs of that activity above the gains to be anticipated from it. Posner suggests that the basic formal structure of law—features such as that compliance must be possible, that like cases are treated alike and that law must be public—can be explained if we suppose that the point of the law is to give people

incentives to do what is economically efficient and suppose that judges are implicitly attempting to determine what would promote that goal. He argues further that the descriptively most adequate theory of the common law treats it as a method for allocating responsibilities among interacting agents so as to maximize the joint value of their activity—that is so as to produce economic efficiency. In his seminal paper Coase showed that standard economic theory entails that if there are no costs to transactions among the interacting parties and if the parties are willing to bargain and trade then any assignment of entitlements among them will be efficient. If efficiency requires that one party have an entitlement it does not have then everyone would be better off if that party bought the entitlement from whoever does have it. If such buying and selling were costless and everyone was willing to buy or sell whenever it was in their interest, then the entitlements would end up wherever it was most efficient that they be. But these conditions are often not met. In particular transaction costs are often quite high. In such cases Posner argues that the law should 'mimic the market'. As he puts it 'Transaction costs are minimized *when the law (1) assigns the right to the party who would buy it…if it were assigned to the other party instead and transaction costs were zero, or (2) places liability on the party who, if he had the right and transaction costs were zero, would sell it'* ([11.12], 18).

Although Posner thinks that his theory gives a good account of the common law he admits that it gives a poorer account of statute law. He argues that this too is explicable on his approach because an economic theory of legislatures will show that they may be expected to be much less concerned with efficiency than are markets or appellate judges. Markets produce efficiency directly and only redistribute wealth incidentally. Legislatures on the other hand have powerful economic incentives to be concerned primarily with the distribution of wealth and only incidentally in efficiency.

Posner ends *Economic Analysis of Law* by leaving as an exercise to the reader the problem *'Can the idea of "justice" as it is used in discussions of law and legal rules and institutions, be deduced from the economist's idea of efficiency? If not are justice and efficiency incompatible?'* ([11.12], 395). Almost all the critical discussion of the Law and Economics movement has been concerned with precisely this question (cf. Coleman [11.2]).

All of the movements with which we have been concerned so far share the view that much, if not quite all, Anglo-American law is justifiable in some fairly full-blooded sense. This position is rejected by the Critical Legal Studies movement.

The Critical Legal Studies movement does not speak with one voice and both its supporters and its critics sometimes treat it rather as a political movement to which one does or does not belong than as a position to which one may or may not subscribe. One of the most central figures in the movement has been Roberto M.Unger, and I will focus on his formulation of its aims and methods. In *The Critical Legal Studies Movement* (1986) Unger describes the movement as having arisen out of a tradition concerned to criticize what he calls formalism and objectivism. Formalism is the view that legal decisions are not political decisions but can be justified by methods of legal reasoning which can be recognized as themselves justified from a standpoint within the law. Objectivism is the view that the legal system as a whole is not merely the resultant of power struggles among competing factions within the society but is justifiable as the embodiment of an objective order of some kind—usually conceived of as a moral or rational order. Unger argues that these two views are mutually supporting and suggests that once the idea that the law embodies objective morality or rationality has been rejected one can see clearly that the project of justifying particular legal decisions by uncontroversial methods must itself be rejected.

The Critical Legal Studies movement positions itself as the heir to the legal realism of Frank, Holmes and Llewellyn and the opponent of both the view which Dworkin represents (what Unger calls the 'rights and principles school') and the Law and Economics movement. Unger calls these watered-down versions of nineteenth-century jurisprudence motivated largely by the fear that if one accepted the critique of formalism

and objectivism then legal doctrine and perhaps even the possibility of normative argument would be undermined. It is understandable that the verbal (and institutional) clashes between the Critical Legal Studies movement and its opponents have been unusually bitter.

It is significant that Unger does not think that Critical Legal Studies undermines either legal doctrine or normative argument. What it does, he suggests, is to continue the legal-realist programme of expanding legal doctrine by bringing both empirical social theory and debate about the right and feasible structure of society explicitly to bear upon the law and legal justification. One consequence of this, he thinks, is to separate political and legal ideals—like that of equality or market rationality—from current conceptions of these ideals, conceptions which treat contingent institutional arrangements as part of the ideal itself. This is to be done partly through detailed historical studies which show how the law typically contains opposing conceptions (principles and 'counter-principles') and show in detail how through political struggles and political deals they came both to be present. This process is illustrated in the law of contract where two conceptions are very much in evidence—one which emphasizes the freedom to choose both with whom to bargain and what terms to accept and another which emphasizes that unfair contracts, no matter how voluntary, are not enforceable. Each of these conceptions can be generalized to a complete theory of contract and each will then treat the core examples of the other as isolated limiting cases. Neither conception by itself can give an adequate account of the existing law of contract and once one sees this one sees also that the concept of contract is not tied to either conception.

The Critical Legal Studies movement sees the law as essentially contested and thinks it highly unlikely that the kind of interpretive project Dworkin proposes—which would yield a theory of the law as a coherent whole—could be carried out for even a very small branch of the subject. The basic reason for this is that the law of a society reflects the history of that society. Since the history of all the larger societies is a history of political and social conflict it is very likely that the law of these societies will itself reproduce these conflicts in the history of precedent cases and the history of statute. At a more abstract level Unger wants to insist (specifically against traditional Marxism) that history is not the working out of a deterministic process but reflects significant choices that could have been made differently. Law will reflect this indeterminism and to attempt retrospectively to impose on these legal choices an explanatory structure which treats the development of law as the unfolding of a single theory is deeply misguided.

It is at this point that the Critical Legal Studies movement intersects currents in contemporary literary theory and contemporary general philosophy. In developing his account of legal interpretation Dworkin appeals to the hermeneutical work of H.-G.Gadamer. In response his critics appeal to other parts of nineteenth- and twentieth-century German and French philosophy—to Hegel, Marx and Nietzsche, to Foucault and Derrida, and sometimes to Heidegger. Dworkin's analogy between legal and literary interpretation has been taken up by deconstructionist critics, lawyers and philosophers who argue that the best picture of texts is not one which treats them as though they were the product of a single coherent authorial intention but regards them instead as more like the field on which various forces and purposes play themselves out. If this is how it is with texts then if Dworkin's analogy holds it will be so with law, and rather than seeking a coherent theory of the law the jurisprudent should recognize its incoherence and its frankly political character. This will involve abandoning legal science as someone like Dworkin conceives it for something more like Unger's expanded doctrine. Philosophical support for these moves is found in Hegel's account of contradictions, in Nietzsche's genealogical account of morality, in Foucault's archaeology of concepts and in Derrida's deconstruction of text (cf. Cornell, Rosenfeld and Gray [11.3]).

THE ENFORCEMENT OF MORALITY

Excepting Law and Economics all of the schools of jurisprudence discussed above agree that there is a deep connection between morality and the sources of law.[1] They disagree fiercely over what that connection is. But morality can also enter the law in quite another way. The law can be called upon to apply legal sanctions to what are perceived to be immoral activities even when no issue of justice or fairness seems to be at stake. The issues involved here are not entirely distinct from the debates in fundamental jurisprudence canvassed above but they have given rise to another literature and another set of connections between law and philosophy.

The contemporary debate about the enforcement of morals at law began with Patrick Lord Devlin's 1958 Maccabean lecture to the British Academy which criticized the recommendation in the 1957 Wolfenden Committee Report that homosexual relations between consenting adults be de-criminalized. The Wolfenden Committee offered the ground that sexual relations between adults were a matter of private morality and that the state had no business regulating private morality. This recommendation echoed the views of the drafters of the Model Penal Code published just two years before in the United States and suggested a trend in Anglo-American jurisprudence. Against this line of thought Devlin argued that the distinction between private and public morality which it presupposed could not be sustained. In 1963 Hart entered the debate with his lectures published as *Law, Liberty and Morality*. Devlin replied in 1965 with his *The Enforcement of Morals*.

Hart's defence of the Wolfenden Report rested on an appeal to and defence of a principle which he found in Mill's *On Liberty* and which has become known as the 'harm principle'. In Mill's formulation it is that 'the only purpose for which power can be rightfully exercised over any member of a civilized community, against his will, is to prevent harm to others' (Mill [11.21]). Mill understood this principle as grounding both liberty of conscience and expression and liberty of tastes and pursuits. Hart agreed and argued that something very like the harm principle lay at the core of a liberal-democratic conception of law. Devlin, on the other hand, argued that such a principle neither could be found in the law as it stood (which criminalized not only homosexuality but also suicide and other self-regarding acts pretty clearly excluded by the principle) nor should be imported into it. At the core of Devlin's argument lay the view that whatever else it may be the law is a means whereby a community exhibits its shared values. Devlin argued that a society is justified in ensuring its own preservation (which is after all why treason is a criminal act). Therefore if the spread of immoral or offensive activity threatens the continued existence of the society the society may prohibit it even if no member of the society is harmed by such acts. An activity can threaten a society's existence in several ways. It can, for example, open a society to conquest or bring it to the brink of civil war. It can also threaten to transform the society in ways which would make it a different society sharing and exhibiting quite different values. A society has a right to protect itself against its destruction in any of these ways. Hart replied that the right of a society to preserve itself against being transformed into another society was much more limited than Devlin admitted. A society had the right to prevent its violent destruction but not the right to prevent its evolution by persuasion.

The Devlin/Hart debate not only reprised the debate between Mill and Stephen (as Hart himself made clear) but also brought into sharp focus the contrast between the liberal conception of the state (which both Mill and Hart accept) and the conception of the state which Hegel espouses in his *Philosophy of Right* and which Devlin and later conservative writers like Roger Scruton (in *The Meaning of Conservatism*) accept.

The debate next moved to the United States. The US Supreme Court, in a series of decisions from *Griswold* vs *Connecticut* (1965) (which struck down a Connecticut ban on contraceptives which extended to married couples) to *Roe* vs *Wade* (1973) (which found that a woman had the right to an abortion in the second trimester of a pregnancy), found in the US Constitution a previously unrecognized right to privacy,

just the sort of right Hart had argued was essential to liberal democracy. Despite this line of cases courts in the US (and elsewhere) steadfastly maintained that the state was under no obligation to permit marriages between same-sex couples (which it was widely recognized were prohibited precisely because they were found immoral and offensive by a large segment of the population). Meanwhile debate over the banning of materials deemed obscene or pornographic continued to grow and to attract the attention of higher courts and controversy arose within some jurisdictions (notably the United States) about whether someone could be prohibited the use of a means to express views because those means were deeply offensive to some person or group (Nazi groups marching through public streets in Jewish neighbourhoods for example) and in other jurisdictions (notably Canada) about whether the dissemination of views which could not be reasonably held to be true and which would incite hatred could be prohibited. In all these issues the adequacy of the harm principle was directly at stake.

At the level of theory there was also considerable development. Eugene Rostow came to Devlin's defence in his *The Sovereign Prerogative* (1962). Dworkin entered the fray in 1966, arguing that there was no right held by a society to enforce a consensus of opinion no matter how deeply held unless that consensus could be defended as a moral consensus, and to be so defended it would have to be shown to be reasonable by the standards of rationality and reasonableness the society and its courts were willing to apply elsewhere. Mere unanimity of feeling did not, he claimed, amount to moral argument. But the most detailed work on this subject has been by Joel Feinberg and is systematically presented in his four-volume *The Moral Limits of the Criminal Law* (1984–8). Feinberg focuses on four principles which have been supposed to provide reasons for criminalizing behaviour. The first is the harm principle. The second is what Feinberg calls the offence principle—that an act's seriously offending others can be a reason to prohibit it. The third is legal paternalism—that an act's harming the agent can be a reason to prohibit it—and the fourth is legal moralism —that an act's profound immorality can be (by itself) a reason to prohibit it. Feinberg accepts both the harm principle and the offence principle but rejects both legal paternalism and legal moralism. In the case of legal moralism he thinks that there is no essential connection between something's moral status and someone's welfare in even the widest sense and so the mere fact that an act is morally reprehensible is no ground for prohibition. Feinberg wants to reject legal paternalism but admits that a person can, even voluntarily, undermine her own interests. This consideration is trumped he argues, by the interference with personal autonomy the prohibition of such acts would require. By accepting the offence principle Feinberg distances himself from Mill. He motivates this distance by having us imagine a 'ride on the bus' during which a remarkable set of very unpleasant incidents occur, all of them quite intentionally produced by others without any concern for their obvious unpleasantness to you. Feinberg argues that these are clearly evils for you, though evils of a sort he thinks different from harms, and that you are wronged by them. Hence the state may prohibit them.

Dworkin, Feinberg and Hart consider themselves to be articulating the attitude liberalism should take to the enforcement of morals but it is hard to find a principle which distinguishes them all from Lord Devlin. Dworkin's disagreement with Devlin is not about whether the community's morality counts but about what counts as the community's morality. Hart's disagreement with Devlin is about whether it is the community's morality as distinguished from 'such universal values as individual freedom, safety of life and protection from deliberately inflicted harm' (Hart [11.19], 70) which licenses prohibition. Feinberg's disagreement with Devlin is over whether anything which does not count as a harm or offence to another person could ground prohibition. These are such different grounds for argument that one is led to wonder whether they are unified by more than the conclusion that certain kinds of sexual conduct should not be criminal.

In recent years the discussion of the enforcement of morality has focused in the United States on whether pornography should be banned. Among the theoretical issues involved has been whether the harm principle justifies such prohibition. Some of this discussion has turned on whether pornography harms individual women or women as a class by increasing the incidence of violent sexual crimes but there have also been several attempts to argue for new categories of wrong and to extend the 'traditional' harm principle to them. For example Andrea Dworkin and Catherine MacKinnon [11.17] have argued that pornography harms women not by (or at least not simply) by causing acts of sexual violence but by creating a climate of values in which it is more difficult than it should be to see such acts as having the scope and gravity they should be seen to have. In more recent work MacKinnon [11.20] has argued that pornographic depictions should be conceived not merely as semantic vehicles but as acts with the power to harm.

PUNISHMENT

Perhaps the most basic question in the criminal law is what justifies punishment. This question can be understood either as asking for a justification of a penal system or as asking what explains how a society is justified in treating a criminal very differently from either a tortfeaser or someone who has innocently caused a harm.

Contemporary discussion of the first reading of the question begins from Calabresi and Melamed in 'Property Rules, Liability Rules and Inalienability' [11.31]. Calabresi and Melamed distinguish between a system of property rules and a system of liability rules. A system of property rules recognizes rights or entitlements which holders can transfer at will but of which they may not be deprived without their consent. A system of liability rules recognizes rights or entitlements may be taken from the holders provided the holders are fully compensated. Calabresi and Melamed point out that when the cost of obtaining a holder's consent is high it may be more efficient to have a system of liability rules than a system of property rules. Reflecting on this issue Robert Nozick (in *Anarchy, State and Utopia* [11.28]) raises the question why not simply have a system of liability rules. Since no one would take an entitlement and fully compensate the holder unless it improved their own situation and since the compensation guarantees that the holder is not made worse off any taking would be a Paretoefficient move. Why not then encourage such takings?

Nozick points out that in economic terms such a system would be one which sets the price of every entitlement at the minimum the holder would take for it. It thus solves the problem of setting a 'just price' in a way that is systematically advantageous to the buyer. He suggests that this is unfair to the holders of goods —who could reasonably hope to do better if their consent were required and who, Nozick argues, have a natural right not to have their goods taken without that consent. (Except in unusual situations: Nozick seems uncertain about the rights of holders when the transaction costs are indeed prohibitively high.) Nozick's conclusion is that a system of property rights is necessary, not for the sake of efficiency but to protect the natural rights of holders. If 'thieves' were only required to compensate their victims they would have no incentive not to take first and compensate later so without punishment in addition to compensation a system of property rights would collapse into a system of liability rules. Hence a society which endorses property rights has an incentive to have punishments as well as compensation.

This ingenious argument does not immediately justify punishment in the sense of the second reading of our question. Even if a system of punishment is a necessary condition for a system of property another argument is required to show that this is not a *reductio* of the view that property rights are themselves justified. This argument has been surprisingly difficult to produce. The argument is required because punishment involves doing to the guilty what it would be impermissible to do to the innocent—depriving

them of life or liberty or some of the means they might otherwise use to pursue happiness. But it is far from clear exactly how the mere fact that someone is guilty could justify such deprivation.

Contemporary justifications of punishment are usually classified as consequentialist, retributive or communicative—though these labels are ill-fitting Among consequentialist theories most focus on the uses of punishment either as a deterrent to crime or as a way of rehabilitating the criminal while others focus on such effects as the greater security punishment yields the innocent. Retributivist theories argue that punishment is deserved by the criminal and communicative or educative theories hold that a crime makes it appropriate to send the criminal a moral message and that punishment does this.

Theoretical work in the first part of this century was largely consequentialist and emphasized the benefits of criminal rehabilitation. In the early 1970s the influence of this approach began to wane. On the one hand behavioural psychologists argued that punishment was less effective than reward as a method of behaviour-modification and on the other rising crime rates and statistics which indicated that existing rehabilitation programmes were a failure combined to suggest that rehabilitation could not justify the existing penal system. At a more theoretical level there was increasing concern that some practices involved in rehabilitation, notably that of indeterminate sentencing, were unjust.

More recent discussions of consequentialist theory have focused on deterrence and on the benefits of keeping criminals off the streets. Here again there has been little clear evidence that the punishments Anglo-American jurisdictions apply deter crime (especially murder and other very serious crimes) and increasing evidence that the societies cannot afford to incarcerate (or legally execute) enough of those whom their policies classify as criminals to induce a sense of security in their cities. Moreover deterrence-based theories of punishment conflict as badly as do rehabilitative theories with the strong intuition that there should be some proportion between the crime and its punishment. If deterrence requires that the expected value of the crime be lower than the expected value of not committing it then one could anticipate that the punishment required for deterrence would vary inversely with the likelihood that the criminal would be caught. Since this likelihood seems to have no necessary connection to the seriousness of the crime then the punishment required for deterrence will have no such connection either.

Perhaps the most interesting recent theoretical work on deterrence theories of punishment has grown out of reflection on the general structure of deterrence. One deters an agent by instilling in that agent a fear of the consequences of his act. One way of doing that is to threaten the agent with harm. When then is one justified in threatening an agent with harm? Several authors (notably Warren Quinn and Dan Farrell) have seen a connection between such cases and cases of selfdefence. Farrell has suggested that the right to self-defence can itself be grounded in a moral permission to distribute harms in such a way that they fall upon the agent who is acting wrongfully rather than upon her innocent victim. He suggests further that one has a moral permission to undertake a plan of action which would so redistribute the harms and therefore that one has a moral permission to undertake a plan of action which would threaten to redistribute the harms. But a plan of action which involved such threats but did not involve carrying them out would not be a credible plan and so would not redistribute the harms. Hence one has a moral permission to a plan of action which involves threatening to redistribute harm which would be wrongfully done one so that it falls on the wrong-doer instead and involves carrying out that threat. Just as I may knock out a thief who attempts to steal my purse so I may threaten to knock him out if he does steal my purse and I may carry out my threat. Such a theory has the advantage over other deterrence theories that it supplies a natural way of setting limits upon punishment parasitic upon the acceptable limits on the force one may use in self-defence. This approach to punishment builds upon a lively recent debate about deterrence sparked by work of Gregory Kavka.

Most of the theoretical work on the theory of punishment in the past quarter-century has been within the broad framework of retributivism theories. Retributive theories argue that by committing her crime the

criminal deserves punishment. Most of the recent work on such theories has been done within rights-based ethical frameworks and so has had to face the question of how it is that the criminal no longer has the rights one ordinarily has within a system of property rules not to be killed, incarcerated or deprived of one's property without one's consent. Contractarians about morality have been tempted to the view that by his crime the criminal voids society's contract with him and so relieves others of their usual moral and legal obligations to him. This approach seems to share the difficulties traditional consequentialists have had in explaining why punishment should be proportional to the gravity of the crime. If something no longer has moral or legal standing then it would seem the issue of proportionality should not arise. But it seems clear that in criminal cases it does arise. Those among retributivists who hold that rights are natural have been less tempted to think that criminals forfeit them than that they are overridden by other considerations. The difficulty here has been to reconcile this with the idea that rights are in some sense absolute and cannot be balanced by other considerations.

Among the most interesting recent work on punishment has been the communicative theories advocated by R.A.Duff and J.Hampton. These theories owe something to Plato and Hegel and something also to Nozick. Hampton [11.26] argues that punishment is justified because a society has a moral right, and perhaps even a moral duty, to convey basic moral and legal principles to its members. Sometimes this can only be done or can be best done by a vehicle which will make a deeper impression than mere words would and perhaps especially conveying to them what it is like to be the victim of a crime. Punishment then is a kind of 'act speech' which communicates values in a striking way. Moreover, Hampton argues that it is the only kind of communication which is necessarily connected with the goal of moral education because it is the only kind of communication which shows the criminal both that her behaviour is wrong and what is wrong about it. Hampton's view is that the state may not use these methods upon all its citizens because the value of autonomy is a strong one which cannot be lightly overridden. The presumption has to be that a citizen understands the basics of morality and law and has the ability to apply them unless she shows otherwise by her behaviour. The latter is precisely what the criminal does. Hampton is insistent that this theory holds punishment to be education and not conditioning and must respect the autonomy of the criminal to the extent this is compatible with communicating the message. Thus she thinks the theory has the resources to explain the intuitive limits on punishment (related presumably to how morally blind and incapable the criminal, as evidenced by the crime, has shown himself to be). Hampton's is a general theory of punishment and her illustrations focus on the ways in which parents educate their children morally through punishment.

Part of what fuels both classical retributivist and communicative theories of punishment is the conviction that consequentialist theories are incapable of treating a criminal as someone who has voluntarily done wrong rather than as something more like a mechanism which has malfunctioned. Thus both retributive and communicative theories insist that the criminal's free choice in the commission of the crime must play a role in the account of punishment. The communicative theorists, for example, regard the criminal as a participant in a communicative situation who has herself spoken and who is being pressed to listen to a reply which she may or may not accept. This emphasis on the criminal's free choice plays an essential role in another theory of punishment which seems to escape the classifications offered above. John Finnis suggests (in *Natural Law and Natural Rights* [11.8]) that we can provide a satisfactory account of the justification of punishment by regarding it as a means to restore the balance of advantages between the criminal and the law-abiding which the criminal has disturbed by his crime. Part of this balance is restored by the ordinary methods of compensation and restitution but, Finnis argues, the criminal has stolen another advantage which is precisely that of exercising his free choice without regard for the consequences to others. To deprive the criminal of this advantage his free choice must be (at least temporarily) restricted beyond the

scope permitted the law-abiding. Finnis thinks that it is this that punishment does and its doing so explains why it usually takes the forms of incarceration and deprivation of resources needed to exercise choice.

CAUSATION, RESPONSIBILITY AND TORT

The classic among contemporary works on causation and responsibility at law is H.L.A.Hart and Tony Honoré's *Causation in the Law* (1959). Hart and Honoré painstakingly analyse the concept of cause as that is used both by philosophers and by lawyers and apply their analysis to issues of legal responsibility. Hart and Honoré are concerned to chart a careful path between those whom they term 'causal minimalists' who in the extreme deny that the question of who caused a harm or loss is at all relevant to the issue of who should be held liable and 'causal maximalists' who argue in the extreme that issues of liability should be settled entirely by reference to causal criteria. Their own view is that the paradigm cases of liability are those in which that liability falls on the party which caused the harm or loss but that these cases by no means exhaust the subject. There are, they point out, clear cases in which a party may be liable though having no causal connection whatever to the act for which they are held liable—an insurer or guarantor may be liable for acts caused by the insured for example. There are also a variety of cases in which a party is liable though their conduct was not the cause of the harm in the ordinary sense of cause but at most an occasion or what lawyers and medieval theologians call a *sine qua non* cause. And there are cases, notably in the law of negligence, where an agent is merely an occasion but is held liable.

The connection between responsibility and causation is an issue in moral as well as legal theory and practice and has received considerable attention in both quarters since the publication of *Causation in the Law*. The entire contemporary debate has been conditioned by the difficulty of giving an adequate analysis of causation. Two recent philosophical analyses have received special attention. One is J.L.Mackie's treatment (in *The Cement of the Universe,* [11.37]) of a cause as an insufficient but necessary member of a minimal set of conditions jointly sufficient (but not necessary) to produce the effect. The other is David K.Lewis's analysis of 'A is a cause of B' as 'A and B and if it were not the case that A it would not be the case that B' [11.36]. Neither of these accounts distinguishes between what Hart and Honoré would consider causes and what they would consider occasions or *sine qua non* causes. Given that the most influential philosophical accounts of causation do not make that distinction it is not surprising that much legal theory has refused to do so. Since in a typical case of tort both parties will be *sine qua non* causes of the harm done and in a typical crime the behaviour of both criminal and victim will be *sine qua non* causes of the crime, then if the best analysis of causation cannot distinguish *sine qua non* causes from other causes, there will be no causal principle which will distinguish the roles of the parties. In that case the law will have to rely in general on something other than causation to settle liability. This position has long been advocated by Leon Green but has received important impetus on the one hand from the recent general willingness to treat 'factual' issues (like questions of who caused what) as being themselves partly normative issues, and on the other from the rise of the Law and Economics movement which claims that tort law (and the common law more generally) can be adequately interpreted as pursuing the goal of economic efficiency—a goal which does not require settling causal issues between the parties. One can then reconstruct the reasoning of Hart and Honoré's causal minimalists as follows: 'In almost any situation in which a harm occurs that harm would have been avoided by a different behaviour on the part of any of the parties. Thus the behaviour of each of the parties is a cause of the harm. We should then regard the harm as a joint product of the activity of the parties and treat the question before us as that of dividing the joint product between them. Since our best theories of causation give us no grounds for distinguishing the contribution of the parties to the joint product we must look for a non-causal (legal or moral) principle which does.' At this point we should expect

causal minimalists to begin to disagree as they propose different normative bases on which to divide liability, and they do.

Although little of the recent work on causation would make one sanguine about using causal principles from outside law and morality to settle issues of liability or blame the revival of moral and legal theories which emphasize individual autonomy and agency points in a different direction. For example Alan Donagan's *The Theory of Morality* (1973) takes it as the standard case that one is morally responsible for exactly that for which one is causally responsible and then proceeds to discuss deviations from this standard case. R.A.Epstein maintains that one should be held liable for exactly what one causes according to a number of paradigmatic causal scenarios. Such theories presuppose an account of causation adequate to their needs.

OTHER SUBJECTS

The areas discussed above have been the most central and most active parts of the philosophy of law in recent years but they do not exhaust the subject. In particular there is the issue of group or collective rights. In several common-law countries (notably Canada and New Zealand) questions about the existence of collective moral and legal rights are of immediate legal and political importance and if the apparent trend towards multicultural and multilingual societies in the common-law countries continues these issues will become more widely pressing. At the theoretical level the philosophical issues involved have been recently explored by Will Kymlicka in *Liberalism, Community and Culture* (1994) and some of the legal issues involved have been treated in a special issue of *The Canadian Journal of Law and Jurisprudence* (1991 [11.38]) devoted to collective rights. There is every indication that this will be an increasingly important area of the philosophy of law in the near future.

NOTE

1 And one could argue that Law and Economics should not be excepted because economic efficency could be understood as a moral ideal.

CHAPTER 12
Applied ethics

Justin Oakley

INTRODUCTION

Applied ethics is a branch of philosophy which employs ethical theory and the methods of philosophical reasoning to illuminate and resolve important practical problems. In so doing, applied ethics addresses issues which go beyond purely theoretical ethical concerns with the systematic justification of moral judgements, dealt with by normative ethics, and questions about the nature of moral statements, which is the province of meta-ethics. Instead of focusing on those theoretical issues, applied ethics takes as its subject matter the more immediate problems confronted in our lives and in the lives of those with whom we share the world. It does so by bringing the distinctive strengths of philosophical analysis and argument to bear on a variety of practical issues such as abortion, euthanasia, warfare and environmental pollution. These are the kinds of issues which feature prominently in our popular press, but the deeper ethical questions they raise receive scant if any attention there.

After many decades of neglect, applied ethics has flourished in the latter half of the twentieth century, and in fact, has probably undergone more growth during this time than has any other area of philosophy in the same period. It would be a mistake, however, to assume that philosophical activity in applied ethics is only a recent phenomenon, for many of our philosophical forebears were actively engaged with practical ethical questions in their writings. Indeed, the distinctions among meta-ethics, normative ethics and applied ethics reflect recent trends towards specialization, and earlier philosophers writing on ethics would have regarded themselves as addressing questions from all three of those domains. Many of the ancient Greek philosophers shared Aristotle's view that ethics is pre-eminently a *practical* enterprise, and this is clearly reflected in their discussions of the ethics of friendship, death and justice in public life. Medieval scholastics such as St Thomas Aquinas wrote dissertations on war and human sexuality, while several centuries later, David Hume, Immanuel Kant and Voltaire dealt with topics such as suicide and world peace. In the late eighteenth century, Jeremy Bentham applied his revisionary utilitarianism to the ethics of capital punishment, and in the nineteenth century John Stuart Mill developed his influential views on liberalism and on equality between the sexes. We can see, then, that representatives of the three main traditions in normative ethics—Aristotelian virtue ethics, Kantian deontology and utilitarianism—all believed it important to consider the ramifications of their theories for the ways we live our lives. This also gives some idea of the diversity of issues examined in applied ethics, and it illustrates the variety of approaches to ethics through which philosophers have attempted to cast light on important practical problems.

In view of this historical background, it is somewhat surprising that philosophers writing on ethics in the first half of the twentieth century did not share this belief in its practical importance and value. Influenced

by the dominant positivist school of thought, according to which all inquiry was modelled on the empiricist methods of science, philosophers regarded normative ethics as speculative and unscientific, because ethics was thought not to be grounded in facts, and hence to be unphilosophical. The proper task of philosophy, it was argued, is to examine meta-ethical questions about the nature of moral judgements, and about how such judgements are to be classified. So in 1936 A.J.Ayer proclaimed that 'A strictly philosophical treatise on ethics should…make no ethical pronouncements', and that 'ethics, as a branch of knowledge, is nothing more than a department of psychology and sociology' (Ayer [12.1], 103, 112). Thus was dispatched normative ethical theory from the province of true philosophy, and its companion, applied ethics, shared the same fate.

The reign of meta-ethics and the antagonism towards normative ethical theory set the agenda for philosophers until the late 1960s, when normative and applied ethics underwent something of a renaissance. The resurgence of applied ethics was a natural consequence of the renewed activity in normative ethics during the late 1950s, which itself grew out of increasing dissatisfaction with the sterility and insularity of the dominant concerns of meta-ethics. This disenchantment with an inward-looking meta-ethics, and the return of philosophers to an examination of substantive questions of normative ethics, was essentially stimulated by the profound and widespread social changes which began in the west in the 1960s. There was enormous questioning of the dominant moral codes of behaviour, and the study of substantive ethical questions began to be viewed as directly relevant to the broader concerns about equality and racial discrimination raised by the American civil-rights movement, and to issues about civil disobedience, pacifism and international justice, raised by the widespread student protests against US involvement in the Vietnam War. Normative ethics, as practised by academic philosophers, began to be seen as offering an important and distinctive perspective on these social developments, and philosophers started moving away from their preoccupation with metaethics and again engaged with substantive issues of broader public concern. Scholarly institutes devoted to the philosophical study of applied ethics began to be set up, pioneered by the establishment of the Hastings Center in New York State in 1969. The motivation for this renewed activity in applied ethics was the recognition of the value of ethics both in identifying the crucial issues at hand, and in lending the rigour of philosophical argument to the burgeoning discussions of those issues.

One of the earliest areas where dominant social values began to be widely questioned in this period was sexuality and personal relations, and here philosophers contributed articles challenging received views on the ethics of contraception, monogamous relationships and homosexuality. These debates fed into others which were beginning in related areas, such as the morality of the law, punishment and civil disobedience. For example, in the United Kingdom in the late 1950s, the Wolfenden Committee's influential report recommending the decriminalization of homosexuality stimulated a lively debate between Lord Patrick Devlin and Oxford philosopher H.L.A.Hart on whether the law should aim to uphold our shared moral beliefs, or to prevent harm to others. Also, Pope Paul VI's 1968 condemnation of contraception, after an earlier papal commission had already supported the use of contraception in marriage, aroused much controversy among moral theologians. Around the same time, many states began to look afresh at whether or not to retain capital punishment, and ethicists discussed whether punishment should seek to exact retribution, or to deter future offenders—a question which had been addressed by philosophers since Bentham. Civil disobedience arose as a major issue in the civil rights debates of the early 1960s, and with the entry of the United States into the Vietnam War in 1961. Although the civil-rights movement made some headway with the introduction in 1964 of the US Civil Rights Act, continuing concerns about widespread discrimination, along with the activation of legislative provisions for civil conscription during

the Vietnam War maintained the focus of many citizens on the issue of whether it is morally permissible to disobey the law, and philosophers began to take up these concerns in their writings.

The Vietnam War and the massive bombing raids which were thereby undertaken also raised renewed concerns about our treatment of the environment, which had been simmering since the Hiroshima and Nagasaki bombings of 1945, and had reached into new areas in 1962 with Rachel Carson's expose in *Silent Spring* of the effects of widespread use of insecticides such as DDT on delicate ecosystems. During the late 1960s and early 1970s, ethicists joined with biologists and anthropologists to protest against our unrestrained pollution and depletion of the world's natural resources, where the earth was regarded as an object to be plundered for our own purposes, rather than as worthy of respect in its own right. This led to discussions of questions of international justice raised by concerns about overpopulation and Third World poverty. What moral obligations, philosophers began to ask, do we owe to the victims of famine? To what degree are we morally responsible for these catastrophes?

Some philosophers and political scientists argued that a major factor in the occurrence of these tragedies was the single-minded drive of western transnational corporations towards profit, at the expense of human welfare of the citizens of the host countries. This led to a major upsurge of activity in an area which came to be known as business ethics. Philosophers began discussing whether, as economist Milton Friedman argued in 1962, the social responsibility of a business corporation was to concentrate single-mindedly on maximizing its profits, or whether private corporations could also be held accountable for the social and environmental consequences of their actions. Spurred on by these developments, ethicists began to reflect on the nature of professional ethics and their relation to ordinary ethical standards.

The relation of ordinary ethical standards of conduct to professional ethics also arose as a question within medical ethics, where doctors were beginning to deal with the novel and difficult ethical issues brought about by developments in modern medical technology. In this context, ethicists turned their attention to issues about death and dying, and about whether doctors and other health professionals have the right to override a patient's request for the withdrawal of medical treatment. These discussions took up older debates about the nature and moral significance of death and the morality of suicide.

The movement supporting equal rights for women raised new areas of debate about equality of employment opportunities and the justifiability of preferential hiring policies. The women's movement also brought questions about the morality of abortion out of the churches and into the public consciousness, where access to abortion became an issue of bitter public debate.

As this brief introduction indicates, the term 'applied ethics' encompasses a broad range of areas in public and private life. There is the ethics of national and international justice, environmental ethics, ethics of health care, reproduction and genetics, ethics in public policy, business ethics, police ethics, engineering ethics, media ethics and the ethics of the legal profession. Three areas of enduring interest in applied ethics are bioethics, environmental ethics and business ethics, and I shall discuss developments in each of these fields in detail. These areas have become more distinct as the study of applied ethics has flourished; however after an initial divergence, there has been something of a confluence of various sub-disciplines under the heading of 'professional ethics'. This has occurred because of the recognition that each field addresses certain common issues, such as whistle-blowing, conscientious objection and the limits of professional responsibility.

BIOETHICS

One of the earliest areas of resurgence in applied ethics was bioethics. Originally coined as a term describing the ethics of population and the environment, bioethics has come to refer to the study of ethical issues in health care, reproduction, biology and genetics. As such, it includes in its ambit medical ethics,

nursing ethics and ethical issues raised in the other paramedical and welfare professions, such as psychiatric care and social work. Bioethics was at the forefront of the renaissance of applied ethics for several reasons. To begin with, advancements in disease control and the development of new medical technologies such as artificial respirators—which could prolong almost indefinitely the life of a comatose patient—led to a re-examination of received views about death, withdrawal of life-support, and the allocation of expensive medical resources. But the rise of bioethics *was* the result of social as well as scientific and technological factors, for in the 1960s there was an increasing move towards the recognition of patients' rights to due care and adequately informed consent. This movement began to broaden its agenda from initial concerns about experimentation on human subjects, which had been an issue since the Nuremberg Trials of 1947 and the subsequent ethical code of practice issued in 1949, to more general consumerist matters of informed consent and patients' rights to treatment without discrimination.

This consumerist movement towards greater recognition of patient rights intersected with the increasingly vocal women's movement of the late 1960s on the issue of access to abortion. After the de-criminalization of abortion by Britain in 1967, and by New York State in 1970, the most significant event for the pro-choice movement was the 1973 US Supreme Court decision in *Roe* vs *Wade,* which held that women have a constitutional right to an abortion in the first six months of pregnancy. Against this social and legislative background, philosophers turned their attention to the morality of abortion with renewed vigour, and this became one of the earliest issues in applied ethics to attain prominence. Before 1970, most twentieth-century discussions of the morality of abortion focused on whether a fetus has a right to life.[1] If this right could be established, it was argued, then abortion is immoral. However, the first issue of the pioneering journal *Philosophy and Public Affairs,* published in September 1971, carried a ground-breaking article on abortion by the American philosopher Judith Jarvis Thomson, which not only changed the face of the abortion debate, but became one of the most widely known and influential articles in applied ethics ever written.

Thomson rejected the premise that the morality of abortion revolves around the right to life of the fetus. By means of an ingenious analogy, Thomson convincingly demonstrated that granting a fetus a right to life does not entail that abortion is immoral. Thomson asks us to imagine that we awake after being kidnapped by the Society of Music Lovers to find our circulatory system connected to a famous concert violinist, who because of his defective kidneys requires the use of our kidneys for nine months in order to stay alive. In this case we would think, and quite correctly Thomson argues, that the concert violinist has no right to the use of our kidneys for that period, and that we could permissibly disconnect ourselves from him immediately, even knowing that this will result in his death. Having secured our assent to this claim, Thomson goes on to argue that the situation with pregnancy (at least when pregnancy is unchosen) is similar in the relevant respects. That is, the fetus, like the violinist, may well have a right to life, but a pregnant woman can nevertheless justifiably abort the fetus, just as we could justifiably unplug ourselves from the concert violinist (Thomson [12.28]).[2] The effect of Thomson's article was to shift the focus of the abortion debate away from the moral status of the fetus and onto he question of the extent of a pregnant woman's right to control her own body, which Thomson herself saw as the fundamental issue.

Thomson's article was seen as providing a solid philosophical basis for the growing pro-choice movement in favour of abortion on demand, and it spawned a whole industry of books and papers devoted to assessing her argument and its implications for the morality of abortion. One issue arising out of Thomson's argument which has been receiving increasing attention is whether a woman's right to bodily autonomy also gives her the right to fetal destruction. This has become important in the wake of advancements in life-supporting technologies for extremely premature infants, whereby progressively younger infants can be saved, for this means that abortion, at increasingly earlier stages of pregnancy, need not entail the death of

the fetus. Also, the legalization of abortion itself raised new ethical questions about research on the aborted fetus.

Another early issue which continues to receive attention was the question of infanticide, especially in the case of severely disabled newborn infants. The most radical view on the morality of infanticide was advanced by Michael Tooley in a highly controversial paper published in *Philosophy and Public Affairs* in 1972. In this paper, Tooley argued that it is not only fetuses which lack a right to life, but new-born infants possess no such right either, and so infanticide shortly after birth is morally permissible. Tooley's argument for this extreme position is based on his contention that it is only persons, rather than human beings as such, which have a right to life. Tooley's central claim is that personhood requires the capacity for self-awareness, which new-born infants lack. The argument for this claim is premised on certain ideas about the nature of rights. Tooley begins by arguing that conferring rights on a being entails that we are obliged to treat that being in certain ways. The next (and most questionable) step in the argument is that we have obligations towards a being in regard to a certain feature only if it is capable of *desiring* that feature, and this in turn requires that it must be able to have a concept of that feature. Tooley then argues that no being can desire that it *continue* existing as a subject of experiences and mental states unless it believes that it is *now* such a subject. However, since infants are apparently incapable of conceiving of themselves as continuing subjects of experiences until at least three months after birth, Tooley concludes that it is not in itself wrong to kill them before they acquire such a capacity for self-awareness (Tooley [12.29]). For a variety of reasons, many rejected Tooley's specific conclusions about infanticide, although many philosophers found his distinction between the moral standing of humans and that of persons persuasive, and went on to apply it to arguments about severely disabled new-born infants, the elderly and ethical issues in our treatment of animals. For example, utilitarians such as Peter Singer and Helga Kuhse have appealed to Tooley's notion of personhood as a morally significant boundary which can be invoked in making non-treatment decisions about seriously disabled new-born infants (Kuhse and Singer [12.19]). However, others have argued that the moral significance of potentiality and parents' duties towards their offspring would rule out infanticide as immoral.

Moving from the beginning to the end of the life cycle, ethical issues in death and dying have been a major focus of discussion in bioethics from the very beginning of its resurgence in the late 1960s. Improvements in dealing with infectious diseases, in organ transplantation and in life-support systems at that time led philosophers and others to reflect anew on the meaning and moral significance of death, and on the ethics of care for the terminally ill. A question which has aroused great controversy is whether it is ever morally justifiable to bring about, by act or omission, the death of a patient at their request, when this is done for humane reasons. Advocates of voluntary euthanasia support the idea that bringing about the death of a patient in these circumstances is morally justifiable, given that the patient was competent when the request was made. Indeed, to hold otherwise, many argue, is to deny a person their right to 'die with dignity'. This position is put forward by both utilitarians (see Rachels [12.24]), who seek to maximize preference-satisfaction, and by some Kantians, who champion the importance of respect for patient autonomy. However, those opposed to voluntary euthanasia argue that a request to bring about death is an admission of defeat, and, moreover, involves usurping the will of God, who alone can decide when a person's time has come.

These debates re-engaged those discussions of the ethics of suicide which were prominent in the writings of some pre-twentieth-century philosophers, but modern medicine's unprecedented ability to sustain life brought hitherto unforeseen issues into the arena. One of the key events upon which much of the contemporary debate has focused is the 1976 New Jersey Supreme Court ruling on Karen Ann Quinlan, who had been lying comatose with respirator support since April 1975. The court supported Karen's

parents' right to withdraw artificial lifesupport, so that Karen could die in peace. Even though after removal of the respirator, Karen actually survived in a persistent vegetative state until 1985, the court's decision provoked great controversy about the implications it was perceived as having for the obligations of healthcare professionals to maintain life-sustaining treatment, especially in cases where the benefits of such treatment to the patient appeared to be negligible. Some ethicists have thought that the justification of voluntary euthanasia centres on whether death is brought about actively or rather by an omission to provide treatment, and they have argued that euthanasia is sometimes justifiable in the latter case, especially where the treatment withheld would be regarded as 'extraordinary means'. Others have argued that actions which bring about death as a foreseen but unintended consequence are morally permissible (see Steinbeck [12.27]). Many utilitarians have responded that these arguments rely on morally irrelevant distinctions, and that the real issue is whether death would be on balance a benefit rather than a harm (see Glover [12.15]; Kuhse [12.18]), although some (e.g. Beauchamp [12.7]) have defended the moral relevance of the active/passive euthanasia distinction on utilitarian grounds.

The Quinlan case and others involving terminal care for conscious patients gave new momentum to the movement to legalize voluntary euthanasia, which had originated in Britain in the 1930s, to press for legal recognition of competent patients' refusals of medical treatment. Indeed, following the 1973 decision by the courts in the Netherlands not to prosecute doctors who provide voluntary euthanasia, ethicists have discussed at length the implications which such liberalization has for the common objection that such a legalized euthanasia leads inexorably down a slippery slope towards a Nazi-style systematic eradication of the 'socially undesirable'. Those who hold such a view also point to the recent advent of self-administered 'suicide machines' and manuals, which have received much media coverage, as further evidence for their claims. The Quinlan case also reopened an old debate about the definition of death, and contributed to a gradual shift away from the traditional heart-lung notion to the now widely accepted brain-death criterion.

The ethics of abortion and euthanasia were at the forefront of the rapidly emerging field of bioethics during the 1970s, but important scientific advances in new reproductive technologies in the late 1970s and early 1980s sparked a second wave of activity in bioethics, which dealt with the novel and fundamental ethical issues raised by those advances. Foremost among these developments was the birth in 1978 of the first baby from *in vitro* fertilization (IVF), where conception occurs in a test tube rather than inside a woman's body. Initial concerns about IVF surrounded the question of whether it is permissible to 'tamper with nature' in this way, or to usurp God's power to create human life (as arose in the euthanasia debate regarding the taking of human life). However, with the enormous growth in IVF programmes in many countries, later issues focused on whether public expenditure on this new procedure could be justified, against the competing claims of preventive health care, which arguably was far more cost-effective (see Singer and Wells [12.26]).

Early feminists such as Shulamith Firestone, who in 1970 proclaimed that 'pregnancy is barbaric', had eagerly anticipated new reproductive technologies like IVF, for their potential to emancipate women from the burden of reproduction (Firestone [12.13], 198). But the advent of these new technologies met with substantial opposition from many feminist ethicists, who argued that such procedures, carried out mainly by males, merely reinforced existing structures of oppression against women, and bring a range of serious risks which are often undisclosed to the women who participate in them. However, some feminist ethicists have recently come out in support of these technologies on the grounds that, when properly conducted, they actually enhance rather than undermine the autonomy of women (see Birke *et al.* [12.9]).

The apparent success of these reproductive technologies gave added impetus to biological and genetic research into embryo development, and the expertise of bioethicists was called on by government bodies in Australia, the UK and the USA to help draft legislation to regulate such research. This research and its

obvious demonstrable benefits raised new questions about the permissible limits of embryo experimentation, and bioethicists turned their attention to discussions about the moral status of the early embryo.

Embryo research and advances in our knowledge about gene sequences also provided new opportunities for pre-natal screening of embryos for genetic diseases and other characteristics, such as sex. This, combined with progress in the Human Genome Project's attempt to map the entire human genome, has brought manipulation of human characteristics through genetic therapy and genetic engineering from the realms of fantasy into reality. These developments raise questions at the frontiers of applied ethics, and bioethicists have only just begun to respond to the call for further discussion of these unprecedented ethical issues. For example, bioethicists are turning their attention to questions about when genetic manipulation for therapeutic purposes might be justified, and whether eugenic genetic engineering is ever morally permissible. Also, the massive genetic data bank being created by the Human Genome Project has raised interesting new questions about the patenting and ownership of genetic sequences and life forms, and about confidentiality in relation to human genetic information.

This brief survey amply illustrates the diversity of issues addressed in bioethics, and indicates how, like many areas of applied ethics, discussions in bioethics draw on knowledge from a range of disciplines outside ethics and philosophy. However, underneath this apparent variety of topics yielded by the spreading branches of bioethics are some common fundamental questions which remain unresolved. For example, the debates on abortion, infanticide and euthanasia have all placed the traditional Christian notion of the sanctity of human life under critical scrutiny, and adherents of this view have been challenged to give an account of the extent, if any, to which quality-of-life considerations may be permitted to influence decisions to bring about the death of a human being. This challenge has been issued by writers who believe, contrary to the sanctity-of-life view, that different human lives may vary in value, as is suggested by our sense that death at certain stages of life may be significantly more tragic than it would be at other stages. For instance, dying just prior to the fulfilment of one's major goals is arguably more tragic than dying before the 'journey' of one's life has begun, or after it has been completed (see Singer [12.25]). Given that our greater technological capacity to sustain human life often comes at great expense, the question of justice in the allocation of health-care resources is also beginning to assume centre stage, especially in the wake of the widespread influence of economic rationalism in the late twentieth century. A range of bioethicists writing on justice in health care have drawn on the work of political philosophers such as John Rawls, in the Kantian tradition (see Veatch [12.30]; Daniels [12.11]), and Robert Nozick, in the libertarian tradition (see Engelhardt [12.12]), in order to provide the moral grounds of a system of healthcare resource allocation, and this is an area where much work can be expected to be done in the future. Among other unresolved issues which arise in several contexts are questions about the value of privacy, and its implications for determining when the confidentiality of patients with HIV and other infectious diseases might justifiably be breached. Also, the increasing use of advance directives in health care raises questions about personal identity over time, and about the conditions under which paternalistic intervention in patient care may be justified, and further work remains to be done in this area.

A feature of the bioethics movement, however, is its capacity to reach consensus on certain fundamental points. Most notably, there is widespread agreement on the importance of personal autonomy for justifying decisions in patient care, and this concept plays a major role in the arguments of many writers in such areas as the ethics of reproductive decisions, medical experimentation and the permissibility of euthanasia. In particular, the rise of informed consent from a specific doctrine in medical experimentation to a general and virtually inviolable principle in patient care, is testimony to the priority given by bioethicists to the value of autonomy, upon which this principle is based. Indeed, the principle of informed consent has been supported by bioethicists from both the utilitarian and Kantian traditions (see Beauchamp and Childress [12.8]). There

is also a significant degree of agreement on the point that the citizens of a just state have a right to a certain minimal level of health care, and that this care ought to be distributed at least partly according to the needs of the potential recipients.

We can see, then, that bioethics has been quite successful in identifying, examining and in some cases resolving a variety of practical issues; however, bioethics is not simply the mechanical application of ethical theories to practical problems in health care. For the discussion of these practical issues has led in turn to a certain reorientation and re-examination of various aspects of ethical theory itself. This reflexive focus on theory has taken two different forms. First, there has been some adjustment in what are perceived to be the paradigmatic problems of moral practice against which any adequate ethical theory is to be tested. So, for example, the concept of personal autonomy has been accorded a great deal of moral weight in justifying decisions in health care, and so any ethical theory which seeks to be action-guiding in bioethics must be able to account for the importance of personal autonomy. The value of autonomy is naturally explained in Kantian ethics, with its emphasis on right action being determined by humans as self-legislating moral agents. Utilitarianism, however, has traditionally had difficulty in adequately capturing the moral value of individual autonomy, given utilitarianism's single-minded concern with maximization of overall well-being, although recent utilitarians have been making concerted attempts to give autonomy due recognition. Another case where practical issues have redirected the focus of ethical theory is in the renewed attention being paid to the nature and moral significance of personal identity, in light of debates about brain death.

The second way in which attention to issues in bioethics has influenced ethical theory is more fundamental. That is, the very concepts in terms of which these theories are defined and articulated have changed in some instances, as a result of difficulties in applying them to practical problems. For example, Bentham and Mill's classical formulations of utilitarianism in terms of maximizing subjective experiences of pleasure and happiness are regarded as vague by many modern utilitarians, and later writers cast utilitarian theory in terms of maximizing the satisfaction of interests or preferences (e.g. see Hare [12.16], [12.17]). This move has been made partly as a way of broadening the moral sphere to allow consideration to be given to the interests of beings who may not at that time be undergoing any experiences, such as future generations and the comatose, and it has also been influenced by applications of economic theory. Another example of such theoretical modification is the way in which modern Kantians such as Onora O'Neill have focused on the immorality of deceptive and coercive institutions, rather than on the direct application of Kant's categorical-imperative procedure itself (see O'Neill [12.21–3]). And finally, the initial move to subsume professional ethics within broader-based universalist ethical theories has provoked a contrary trend to revive a distinctive medical ethic, grounded in the particularities of the doctor-patient relationship, which modern formulations of virtue ethics and feminist ethics of caring have been thought by some as especially able to capture.

Thus, there is to some extent a dialectical relationship emerging between applied ethics and ethical theory, with each challenging and forcing amendments to the other, in response to their application to the kinds of practical problems discussed above. Also, there is some overlap in the underlying issues addressed by bioethics, on the one hand, and environmental ethics and business ethics, as we shall see.

ENVIRONMENTAL ETHICS

Turning from bioethics to environmental ethics, one may initially be struck by the differences between the kinds of issues addressed by these two fields of applied ethics. However, both these movements share common roots in the widespread challenges to popular consciousness during the 1960s, and both raise certain common underlying ethical issues which are difficult to resolve. Broadly speaking, environmental

ethics deals with questions of rightness and value regarding our relationship with the rest of the natural world. As such, environmental ethicists discuss issues which arise in relation to pollution, the exploitation of natural resources, overpopulation, our attitudes towards and treatment of animals, and the value of ecosystems themselves. In doing so, discussions in environmental ethics often proceed by identifying the kinds of values or features which are at issue, and by attempting to determine, in light of those values or features, what various ethical theories or principles would have us do.

The beginnings of environmental ethics in the twentieth century can be traced back as early as 1915, when Albert Schweitzer began to develop an ethics based on 'reverence for life', in which he included animals, insects and plants as well as human beings. This expansion of the realm of value was quite explicitly taken further during the 1930s and 1940s by the American ecologist Aldo Leopold, in his book *A Sand County Almanac* (1949), which promulgated a holistic 'land ethic', whereby value was attributed to the whole integrated biosphere of landscapes and ecosystems, rather than merely to individual life forms (Leopold [12.37]). This was a precursor to the 'deep-ecology' movement of later decades, which, as we shall see, developed a quasi-spiritual view of the intrinsic value of the biosphere.

However, activity in environmental ethics took a quantum leap during the 1960s, with mounting concerns about pollution, resource depletion and overpopulation. The watershed of the environmentalist movement was Rachel Carson's revelations in *Silent Spring* of widespread land degradation resulting from the use of chemical insecticides such as DDT (Carson [12.32]). The exposure by Carson of the poisoning and fracturing of fragile ecosystems broadened existing public concerns about toxins in food and the environmental effects of nuclear fall-out. Carson's highly influential book, which she dedicated to Albert Schweitzer, forced many to reconsider their instrumentalist attitude to the natural world as an inexhaustible 'resource' which could be unthinkingly used for human edification.

This reassessment led to the formation of broad environmentalist movements, which began to gain a great deal of exposure through public events such as 'Earth Day' in 1970, where American Senator Gaylord Nelson called for every American's 'inalienable right to a decent environment' to be enshrined in the constitution.[3] The word 'green' began to be used as a verb to denote the development of a commitment to environmental concerns. There was also discussion about whether pollution and overutilization of land violated the rights or interests of future generations to inherit a world which was still livable. Some ethicists argued that, as with spatial distance, temporal distance between populations is irrelevant to setting our moral obligations, and so decisions about the utilization of non-renewable resources must make allowance for our duties towards future inhabitants of Earth. This argument draws on intuitions shared by many about our duties to generations in the not-too-distant future, such as our children, but some philosophers objected to this argument because of the epistemic difficulties in foreseeing what the interests of generations in the distant future will actually be.

These concerns about environmental degradation took on a new urgency with the so-called 'energy crisis' in the 1970s, where many became aware that the known reserves of oil and other fossil fuels, on which much of the world's economy depends, were diminishing at an alarming rate. The recognition of the finiteness of these conventional energy sources inspired developments in alternative energies such as nuclear power, but these carried environmental problems of their own. Concerns about resource depletion also gave rise to a variety of theories which sought to explain this phenomenon. A controversial explanation, tracing the problem to demographics, was offered by Paul Ehrlich in his 1968 book *The Population Bomb.* Echoing Malthus's eighteenthcentury views, Ehrlich argued that the environmental crisis was due to the burgeoning world population, which was doubling in size approximately every forty years, and to the resulting exponential increase in the consumption of non-renewable resources (Ehrlich [12.33]). Ehrlich's argument, which pointed to the increased consumption arising from the desire for higher living standards, also raised

questions about the ethics of private corporations deriving profits from meeting desires induced by increasingly sophisticated methods of advertising, which I shall discuss later under business ethics. Ehrlich's claims also intensified the debate about the ethics of contraception, discussed in the previous section, for the widespread availability and use of contraception was championed by many as an answer to the dangers of overpopulation. The overpopulation argument also raised some fundamental questions about the extent of the western world's moral responsibility for and duties regarding the plight of populous but underdeveloped Third World countries stricken by famine and poverty.

The question of moral responsibility also arose in relation to scientists whose research had the potential for application in areas which carried hazards of environmental degradation and pollution, such as agriculture, genetics and weapons research. Here ethicists challenged the appeal to ignorance of consequences, or the attempt to diffuse responsibility over the research organization, which scientists often invoked as a way of excusing themselves from the burden of responsibility for the harmful environmental applications of their research. This led to increased attention being paid to questions about foreseeability, culpability and collective responsibility.

However, during the 1970s the early focus on the human impact of environmental destruction began to be regarded as too narrow and 'anthropocentric', and started to be supplanted by an ever increasing expansion of the ethical sphere to include animals, plants and eventually all life forms. This move was being driven largely by philosophers, whose concerns about the environment led them to reconsider traditional assumptions about the boundaries of moral value and moral recognition, and it was really only with the advent of systematic reflection on these deeper considerations that a distinctive and recognizable movement in environmental ethics began to take shape. An indication of this coalescing of concerns was the appearance in 1979 of the first issue of the international journal, *Environmental Ethics*.

One of the earliest issues in this expansionist movement, which bore clear philosophical roots in ethical theory, was the call to include animals in the moral domain. Thus, drawing on the civil-rights movement's rationale for extending proper moral consideration to blacks and women, Australian philosopher Peter Singer's 1975 book *Animal Liberation* presented a powerful argument in favour of granting adequate recognition to the moral status of animals. Condemning common practices in animal farming and experimentation, Singer argued in favour of vegetarianism on utilitarian grounds, and in doing so brought applied ethics to the dinner table, where our eating habits became a matter of ethics rather than simply of etiquette. Singer argued that the principle of equal consideration of interests underlying arguments against racism and sexism entails that discrimination against beings solely on the basis of their species, or *speciesism,* is also unjustifiable. For any being which has the capacity to suffer thereby has interests which, opponents of racism and sexism must in all consistency agree, ought to be given equal consideration. Therefore, since all animals (except perhaps molluscs and some other invertebrates) have the capacity to suffer, and to experience suffering in much the same ways as humans (given the physiological similarity and common evolutionary origin of their respective nervous systems), all such animals are entitled to equal moral consideration. And if we accept that causing such suffering is morally wrong, then we ought to reform our attitudes towards and treatment of animals (Singer [12.46]). *Animal Liberation* touched the lives of many people, and lit the candle of the animal-liberation movement. Some ethicists extended Singer's arguments to campaign in their writings against zoos and animal blood sports, and began to investigate different approaches to establishing why and to what extent animals can justifiably be included in the moral sphere.

With the rapid diminution and extinction of plant as well as animal species occurring during the 1970s due to industrial, transportation and urban-land developments, the environmental movement lobbied successfully for legislative changes to protect endangered species, which resulted in the Endangered Species

Act being passed in the United States in 1973. These popular and legislative moves led some ethicists to fix their gaze more broadly, and they began to focus on the difficult question of why, if at all, we ought to preserve diversity of species. This broke new ground in applied ethics in two ways. First, the variety-of-species question was taken up in a *general* way, without giving the human species undue priority, and it took the preservation of orchids and other plant species to be an ethical issue. But second, and more fundamentally, the *reasons* which environmental ethicists began to offer for the importance of maintaining species diversity went beyond the value of species to us as humans. That is, while some ethicists argued for preserving biological diversity by appealing to the value of natural variety in enhancing our understanding and appreciation of nature, others argued that whole ecosystems themselves have intrinsic value, and that the value of a particular species could be seen in terms of its importance for maintaining the integrity of that ecosystem (see Norton [12.42]).

This embracing of ethical value in aspects of nature itself found inspiration in the earlier ethics of Schweitzer and Leopold, and was taken even further in the 'deep-ecology' movement, which began in 1972 with a landmark article by Norwegian philosopher Arne Naess, who drew a distinction between shallow and deep approaches to ecological ethics. Naess argued that environmental movements which were motivated by 'shallow' ecological concerns were inadequate, since they operated within the traditional anthropocentric framework, whereby the environment had value because of its contribution to human wellbeing. A 'deep' ecological movement, on the other hand, was committed to maintaining the intrinsic value of the whole biosphere for its own sake, rather than simply for our human edification (Naess [12.39]). There are several varieties of deep ecological theories, grounded in a range of different metaphysics. Some deep ecologists, who regard nature as an extension of themselves, have been criticized as chauvinistic by writers such as Richard Sylvan, who argues that such approaches fail to recognize the otherness of nature and its profoundly non-personal character (Sylvan [12.48]).

This notion of an environmental ethic grounded in the intrinsic value of all nature inspired many writers to go on and develop their own variants of a life-centred or biocentric ethics, and some went beyond this by arguing that even *inanimate* nature has its own independent standing or its own intrinsic value. For example, in a highly influential 1972 paper, legal philosopher Christopher Stone argued that trees, forests, rivers and oceans ought to be recognized as having legal rights. Stone's argument for this claim begins by making explicit the criteria for an entity to have legal rights, which include the provision that legal actions can be instituted *on its own behalf,* having injuries *to it* taken into account by the courts in determining legal relief, and having compensation awarded *to its own benefit* (and not merely to a guardian). Stone then offers a systematic critique of the prevailing legal position on the environment, arguing that there are no good reasons for holding that natural objects cannot fulfil these criteria. Stone suggests that the legal problems of a natural object can be handled by appointing a guardian to act as an advocate for its needs and interests, as is done with persons who have become legally incompetent, and he argues that the cost of 'making the environment whole' (e.g. through reseeding a logged forest, repairing its watersheds and restocking its wildlife) should be the guiding principle in determining the amount of compensation awarded to it (Stone [12.47]). In the early 1980s the philosophical foundations of this approach were further developed by Kantian philosopher Paul Taylor, who argued for a kind of egalitarian environmental ethics, whereby every living thing is entitled to equal respect as a member of the 'community of life' (Taylor [12.49], [12.50]).

However, other ethicists, such as J.Baird Callicott and Holmes Rolston III, rejected the individualism or atomism prevalent in many theories of environmental ethics. In contrast to these approaches, which emphasized the flourishing of individual members of species, Callicott and Rolston were inspired by the earlier ethics of Leopold to attribute value to the entire community of life forms, land forms and ecosystems as an integrated whole, which was given greater weight than any of its component parts. Thus, in Callicott's

ethics, oceans and lakes, mountains, forests and wetlands are assigned a greater value than individual animals, and even viruses and bacteria are included in the realm of value (see Callicott [12.31]). Indeed, Rolston argued that entities such as stalactites, crystals and even entire planetary systems have intrinsic value (Rolston [12.45]). However, some philosophers, such as animal-rights advocate Tom Regan, have argued that this holistic ecocentrism is really just a form of 'environmental fascism', in its indefensible requirement that the rights of individuals must sometimes be sacrificed to the good of the ecosystem as a whole.

Certain writers have recently sought to give this holistic approach to environmental ethics a metaphysical basis. For example, the Australian philosopher Freya Mathews argues for a Spinozistic 'ethic of interconnectedness', whereby the apparently different features of the natural world are regarded as attributes of the same underlying substance. Mathews endorses English biochemist James Lovelock's claim, in his influential book *Gaia: A New Look at Life on Earth,* that the biosphere consists in systems of self-realizing beings. Recalling Spinoza's notion of *conatus* (or the drive to self-realization), Mathews goes on to argue that these self-realizing beings have equal intrinsic value, although she does allow that some degree of species loyalty is morally permissible. Further, in developing our commitment to our own self-realization, Mathews argues that we come to identify with this *conatus* in other beings, and so become properly disposed both emotionally and practically to safeguard Nature in all its manifestations. (Mathews [12.38]).

The move by ethicists towards a larger picture has also been reflected in a shift in the environmental movement during the 1980s away from an exclusive focus on narrower local issues, such as the preservation of a particular species, towards a more global outlook, with the advent of problems in ozone-layer depletion, the 'greenhouse effect' and consequent global warming. This broader perspective has raised new and challenging ethical issues about international environmental justice, and has brought out interesting tensions between environmental values and the claims of social justice. One example of this tension between competing values which is beginning to receive attention concerns the question of the extent to which it is justifiable for affluent western nations to compel impoverished Third World states to preserve wilderness areas, when the economies of those states are so dependent on exploitation of the land for farming and other activities. The question of moral responsibility for this potential conflict also arises, since some writers argue that western nations have helped to bring about a situation of Third World dependence such that wilderness areas in those countries are now under threat.

In summary then, the movements in the intellectual landscape of environmental ethics can be portrayed as a progressive broadening of our concern for different life forms, corresponding to a gradual deepening in our views of what is valuable. But exactly how far we must extend our ethical concerns in these directions remains a hotly debated issue, and the boundaries between the diverse camps in environmental ethics can by and large be drawn according to the different answers they give to this question.

However, it should not be thought that the proper limits to extending the moral domain can be found simply by rigorously applying the particular ethical theory one is already committed to. For as we saw with bioethics, environmental ethics also has a reflexive aspect, where the application of ethical theory to practice has led to new issues and problems for ethical theory itself. For example, ethicists who had adopted the discourse of rights have had some difficulty in capturing the moral status of animals, plants and landscapes in those terms, and some have subsequently abandoned rights talk in favour of the broader notion of 'interests', which they think is better able to accommodate environmental values (on rights and interests, see Feinberg [12.36]). Others, such as John Rodman [12.44], have reformulated Kant's well-known categorical imperative urging us to treat people as ends in themselves, rather than using them as mere means, and have argued that this principle applies to all living things and natural systems which have ends of their own. More fundamentally, the application of ethical theory to environmental issues has also

cast debates about the nature and importance of intrinsic and instrumental values into a new arena, and has led to some clarification of how candidates for intrinsically valuable entities, such as ecosytems, are related to our valuing them. These debates have connected in interesting ways with other, broader, debates in meta-ethics, such as that between Humean projectivism and moral realism.

Another way in which discussions in environmental ethics have raised deeper issues is in the ecofeminist critique of the very idea of an environmental ethic based on a 'theory' at all. Ecofeminists reject the need for theory as a masculinist prejudice which ignores the reality and plurality of experience, and especially of women's experience. In support of this approach, some writers point to the similarities between man's quest for domination over nature, and his attempts to subordinate women (see Warren [12.52]). Other writers argue that historically, women have experienced a close emotional identification with nature (see Ortner [12.43]), and that women are characteristically more sensitized than men to the particularities and the contextual features of situations. While such large claims cannot be evaluated here, we can nevertheless see that issues similar to those raised in feminist critiques of new reproductive technologies and of abstract ethics, which we noted above in discussing bioethics, are beginning to receive much attention in environmental ethics also.

BUSINESS ETHICS

A third area which has emerged as a distinct and active sub-discipline of applied ethics is business ethics. Generally speaking, business ethics is the study of ethical issues in private enterprise and the conduct of commercial affairs. A variety of ethical issues arises in those contexts, but the attention of ethicists has centred mainly on questions concerning the social responsibilities of private corporations, collective responsibility for environmental pollution and other harms, the morality of bribery and extortion, and the justifiability of whistleblowing against one's colleagues. The orientation of business ethics differs from those of both bioethics and environmental ethics in several respects. To begin with, since business ethics is really a sub-division of professional ethics, it is comparable to such fields as medical ethics and legal ethics. For like those fields, business ethics deals with issues which are somewhat narrower than those addressed in bioethics and environmental ethics, which raise fundamental questions about the moral status of human beings and the value of life itself. Also, unlike philosophers engaged in bioethics and environmental ethics, philosophers writing on business ethics have on the whole not made deliberate attempts to formulate unified theories or world-views within which to explain and resolve the distinctive problems which arise in studying the activities of private corporations. Of course, discussions in business ethics do involve applications and examinations of traditional utilitarian, Kantian, and Aristotelian ethical theories, and there is also some scrutiny of broad political and economic theories such as liberalism, capitalism and socialism. However, philosophers have not by and large tried to develop a distinctive 'business ethic', in any sense analogous to either a philosophical medical ethic, or an environmental ethic such as deep ecology. Indeed, the absence of attempts to articulate an overall business ethic is not surprising, given the variety of different commercial enterprises which business ethicists take as their cases in point, and the absence in business of any general traditional professional ethic, akin to the Hippocratic Oath of the medical profession.

The ethics of business and commerce have been discussed by philosophers since the ancient Greeks and Romans, and such concerns also figure prominently in the Christian tradition of moral theology. But the groundwork for many modern discussions of ethical issues in business was laid by the eighteenth-century Scottish philosopher-economist Adam Smith in his classic text on political economy, *The Wealth of Nations* (1776), which argued that a nation's wealth is maximized by permitting individuals to pursue their own interests, rather than through political intervention to secure some notion of the common good. Despite

these historical antecedents however, it was really only in the late 1970s that the somewhat disparate range of concerns addressed in business ethics were brought together as a unified field of study. The seeds of this emerging field were planted in America during the late 1950s and early 1960s, when the behaviour of private corporations came under closer public and government scrutiny. This increased attention was due to a number of factors, such as the growing consumerist and civil-rights movements during that period, but there was also a significant move within certain corporations themselves to examine conventional business practices, in response to their desire to remain competitive with the resurgent economies of Japan and Germany. These movements raised concerns about such issues as industrial pollution, unjust discrimination, corrupt business practices and the extent to which weapons manufacturers gave impetus to US involvement in the Vietnam War.

It is common to distinguish between three levels of analysis in business ethics. The first and most fundamental level deals with the values arising out of the broad social, cultural, political and economic environment in which the activities of corporations are set, and addresses underlying questions about issues such as the compatibility of the free market with considerations of justice and general welfare. The second level of analysis examines the ethics of corporate behaviour directly, in light of certain background assumptions about the distinctive institutional norms of private corporations, while the third level concentrates on the rights and obligations of individuals within a particular business organization.

Following the concerns raised by the environmental and civilrights movements in the early 1960s, one of the first debates in business ethics concentrated on the fundamental question of whether private corporations have any broader social responsibilities, such as maintaining the environment, or alleviating poverty and suffering, or whether it is morally permissible for corporations to focus exclusively on maximizing returns to their shareholders. One of the principal proponents of the latter view was the well-known American economist Milton Friedman, in his 1962 book *Capitalism and Freedom.* Reacting against what he saw as the rising tide of support for the idea that private corporations have greater social responsibilities, Friedman argued that a corporation is purely an instrument of the shareholders who own it, and so its obligations are owed exclusively to them, rather than to the members of society at large, who have no legitimate claims on it. In Friedman's view, the responsibility for dealing with broader social problems falls into the hands of governments themselves, who already exact contributions from private corporations for broader social purposes in the form of corporate taxation. Friedman also supported his position by invoking Adam Smith's argument that social welfare is in any case often best promoted by allowing private corporations to pursue their own interests, since such activity will be indirectly led by an 'invisible hand' to promote social welfare in ways which are often more effective than any corporate activity which aims more directly at this goal (see Friedman [12.61]).

However, this Friedmanesque plea for laissez-faire capitalism and free-market corporate behaviour was hotly contested on a variety of grounds. Many argued that this approach took a far too narrow and atomistic view of private corporations, since their activities affected not only their company shareholders, but also what are sometimes called their 'stakeholders', such as their employees, clients, consumers and the broader community who live near them (see Solomon [12.68]). This raised the question of whether the realm of interests which must be considered in evaluating the activities of businesses can be justifiably expanded in such ways, and this has become one of the central issues of business ethics. Others expressed scepticism about Friedman's empirical claim regarding the effects of the invisible hand on social welfare, and argued instead that an unregulated laissez-faire market would often have significant undesirable consequences for social welfare.

Another branch of opposition to Friedman's view focused not so much on the general question of whether a corporation's neglect of broader social obligations in concentrating on maximizing profits is

wrong in itself, but instead challenged a specific implication of that view in regard to environmental and other public harms, in cases where a clear causal link could be established between a corporation's activities and those broader ill-effects. This kind of criticism arose largely in response to widespread public concerns about the environmental effects of industrial pollution, and about the safety of food additives and pharmaceuticals, especially with the emergence of the devastating sideeffects of certain drugs, such as Thalidomide. Philosophers started to take up these public concerns, and began to debate conceptual and ethical questions about corporate moral responsibility, and about the extent, if any, to which a body of people (a corporation) could meaningfully be held responsible for wrongdoing. Many argued that where social and environmental harms could be shown to be the direct result of business activities, as in industrial pollution and the manufacture of hazardous products, there is a clear case for holding corporations accountable for those consequences (see Arrow [12.55]). However, other writers, influenced by sociological and legal views of the nature of organizations and their limited liability, argued that the idea of a corporation being held morally responsible for harmful outcomes is incoherent, and contended that the notion of moral responsibility is properly applicable only to individuals.

This debate led to discussions among business ethicists and philosophers about the kinds of entities which moral responsibility can be legitimately attributed to, and they examined whether the organizational decision-making structures involving corporate reasons for actions are sufficiently analogous to those of individual persons to treat corporations as accountable moral agents (see French [12.60]). Some have conceded that corporations can bear *collective* moral responsibility for wrongdoing and be liable to sanctions as a result, but have insisted that they cannot be allocated *distributive* moral responsibility for such consequences, and so responsibility and blame cannot be meted out to individual employees. However, others have argued that in the process of incorporating and co-ordinating the disparate actions of individual employees into a structure of power and responsibility, corporations themselves often have a relatively clear idea of how responsibility is distributed over the organization. Indeed, some have pointed out that a refusal to make these structures explicit has enabled corporations to 'shield' guilty parties from appropriate legal and moral sanctions for their contribution to great human and environmental disasters (see Wells [12.70]). One widely supported suggestion often made in this context is that corporations should develop clearer organizational structures so that individual employees can know what they are and what they will be held responsible for. Many corporations are beginning to take such measures, and this suggestion has also had an impact on professional business-ethics education. However, questions remain about what share of moral responsibility it is justifiable to allocate to individual members of large corporations, in cases where social and environmental harms are clearly the result of the activities of the corporation which employs them. This also raises issues about conscientious objection, conflicting loyalties and whistle-blowing, which we shall turn to later.

The publicity surrounding the harmful social and environmental effects of certain corporate activities also raised deeper questions about the relationship between ordinary and professional standards of mora-lity, which we saw also arose in the context of medical ethics. On the Friedman view, the appropriate guiding norms of business are given content entirely by reference to its overriding single goal of maximizing profits for shareholders. In response to protests from those who sought to demonstrate the wider moral responsibilities of business in a democratic pluralist society, supporters of the Friedman approach drew on the common analogy between business and sports, which have their own internal systems of rules, and where ordinary moral standards are somewhat attenuated. The rejoinder to this, however, has been to point out that even in those seemingly extra-moral enclaves, ordinary moral and legal requirements are not suspended altogether. So, for example, a footballer who uses excessive violence during a match can still be charged with assault. Thus, neither a sportsman nor a businessman can properly be regarded as 'a law unto themselves'. Indeed,

some writers, such as environmental lawyer and ethicist Christopher Stone (familiar from the previous section for his argument that trees should have legal rights), turned Friedman's question around, and asked instead why there is any reason to believe that corporations ought to be *exempted* from the ordinary moral obligations of non-maleficence and beneficence which apply to all members of our society. How can a corporate executive, just in virtue of the role he or she occupies, properly regard himself as immune from ordinary moral obligations in respect to his behaviour in his corporate capacity (Stone [12.69])? This kind of argument drew on interesting work in the morality of roles and their attendant obligations, which some philosophers have argued offers a framework better able to capture the distinctive moral position of a company employee than is provided by analyses in terms of the dichotomy between individual and corporate responsibility. For, as R.S.Downie argued, 'an individual person can act in a public or official capacity…[and] in accepting the role he adds to his share of rights and duties those which go with the role' (Downie [12.59]). This also raised questions about the concept and moral basis of professionalism, and about the limits of professional autonomy, which also arise in medical, legal and other areas of professional ethics.

Another early issue which has received much attention by business ethicists is the ethics of advertising, which became prominent as a result of the massive spread of television and its enormous expansion of markets during the 1950s. An initial skirmish in the early 1960s between influential American economists J.K.Galbraith and F.A.Hayek, on the relationship between advertising and consumer demand, brought out one of the key issues in the debate. Galbraith argued that the effects of television advertising confounded traditional justifications of the free market based on its alleged efficiency in meeting existing consumer demand, because of what he called 'the dependence effect'. This is the phenomenon whereby increases in an individual's wants are directly responsive to increases in the levels of production and consumption, since the production which satisfies existing consumer demand itself often results in the creation of new wants (see Galbraith [12.62]). In other words, as a society becomes better off and more productive, and corporations acquire greater access to advertising, individuals come to develop new desires for material goods, through the influence of advertising and their desire to emulate the affluence of others. James Joyce was aware of this long ago: 'Mass seems to be over. Could hear them all at it. Pray for us. And pray for us. And pray for us. Good idea the repetition. Same thing with ads. Buy from us. And buy from us.'[4] Galbraith argued that the creation of these artificial wants, which could be met only through acquiring more goods, simply increased the spiral of consumption, and he argued that we should concentrate instead on meeting those wants which individuals would experience in the absence of those seductive influences. The creation of wants by advertising illustrated another dimension to the social responsibilities of corporations, and aroused important debates in ethical theory about the moral status of different kinds of preferences.

In response to this, Hayek contended that Galbraith's emphasis on meeting original desires uninfluenced by the existence of products which society makes available is a fruitless search for a chimera, since most of our desires, including those for literature, music and other cultural pursuits, are influenced in some way by socialization. Hayek also argued that the producers of goods are not themselves able to determine what consumers will come to want, since people are able to make free choices about such matters for themselves (Hayek [12.64]), and indeed, advertising arguably performs a useful function in informing people of what products are available. However, as others have pointed out, advertising can properly perform this informative function only if it is honest about the products it promotes, but this may well not be the case, since lying or concealing the truth may often serve the company's interests in selling its products and maximizing its profits. This has led to debates about what level of honesty advertisers are morally obliged to uphold, and whether there ought to be legislative provisions against false advertising to protect the rights of consumers (see Goldman [12.63]).

All these issues have been discussed since the early 1960s by a variety of groups, such as economists, political theorists, corporate executives and the public at large. However, it was not really until the late 1970s that philosophers began to engage in sustained discussions of these ethical issues, and this upsurge of activity is evident in the many anthologies on business ethics which began to appear then (see Bibliography, p. 396). With the publication of the inaugural issue of the *Journal of Business Ethics* in 1982, business ethics became the latest of the three main fields of applied ethics to emerge as a recognizably distinct area of study.

Since becoming involved in business ethics, philosophers have developed the early discussions of broad questions much further, and they have also written extensively on specific issues which arise in the context of the individual employee's relationship with his or her corporation. There has been much recent discussion of the morality of various forms of corruption, such as bribery, extortion and insider trading, and also of the moral responsibilities of individual employees who become aware of such activities within their organization.

Business ethicists have taken an interesting approach to discussing the morality of bribery and extortion. Instead of simply issuing blanket condemnations of these practices, business ethicists have argued that there are various circumstances where such practices may be justified. For instance, since bribery is aimed at influencing a person to violate his or her institutional duties or expected roles, one situation where bribery has been claimed to be morally justified is where the institutional duties or roles of the person bribed are themselves already morally unjustifiable. Some writers also argue that the distinction between bribery and extortion is morally significant, since bribery takes the form of inducements for the provision of special favours, whereas extortion (or, as it is more commonly called, blackmail) involves receiving payment for something one is already supposed to do, but which one threatens not to do unless one receives a certain payoff (see Philips [12.67]). Since bribery involves an inducement to violate impartiality, it has been regarded by many as much more difficult to justify than extortion, which does not involve such a violation, and which utilitarians argue is justifiable in cases where such action would prevent great harm. Another kind of situation where bribery and extortion have been defended is where such practices are an integral part of the customs of a particular country in which one is a guest. This has raised interesting meta-ethical questions about the validity of cultural relativism, but many ethicists reject the relativist position, and so argue that it cannot be used to justify acts of bribery and extortion.

With the enormous profits being made during the stock-market boom of the 1980s, and the equally large losses incurred in the stockmarket collapse of 1987, business ethicists turned their attention to questions about whether practices such as 'insider trading' in company shares are ever morally justifiable. Insider trading involves buying large numbers of shares in a company which one knows through 'inside' information is about to be the target of a takeover bid, and then selling these shares at an inflated price to the company making the takeover bid. Insider trading raises ethical issues because it is a practice whereby employees make a personal profit from confidential information about their company's intentions which they have been entrusted with. Insider trading has been portrayed by some as ethically unobjectionable, on the grounds that it is just another example of the spirit of entrepreneurship upon which the business world is built. Nevertheless, ethicists have argued that insider trading is immoral, for a variety of reasons. For example, Gary Lawson argues that the shareholders of the target company are being deceived into making an unfair trade, since they are selling their shares without knowledge of the impending takeover, and so without knowledge of their true market value. Lawson also argues that insider trading may be thought wrong on the grounds that employees are thereby breaking their promise to their employers not to use their position to seek undeserved personal advantage, and that it may be tantamount to stealing information which rightly belongs to their employers (see Lawson [12.66]).

However, since these practices clearly do take place within the modern corporate world, what have business ethicists advised an employee to do where he is aware of such practices occurring, or is being told to participate in these or other immoral practices himself? These situations are extremely difficult for individuals, especially since the burgeoning numbers of unemployed are likely to make many reluctant to take any action. One course open to employees asked to participate in the immoral actions of a corporation which is, say, causing serious environmental damage, would be to refuse on conscientious grounds to carry out their duties. This kind of situation also occurs in the context of nursing and patient care, and it raises important questions about the moral significance of personal integrity, which has received much recent attention in debates about ethical theory. However, where an employee is aware of wrongdoing within their organization but is not themselves participating in it, under what circumstances would they be morally obliged to 'blow the whistle' on their colleagues? This question about the justifiability of whistle-blowing arises in many areas of professional ethics, and ethicists have given different reasons in support of such action being taken. Kantians argue that whistle-blowing is justified because one's duties to prevent harm and injustice to others override one's institutional duties, while utilitarians have defended such action in cases where the harms one is calling attention to are worse than the harms which occur as a result of one's blowing the whistle (see James [12.65]). These kinds of situations often raise difficult questions about conflicting loyalties, and their resolution may well weigh heavily on the individual who has carried out the whistle-blowing (see Wren [12.71]).

We can see then, that business ethics often brings out vexed questions which require deeper analysis in terms of ethical theory before they can be resolved. Nevertheless, business ethics does not generally raise ultimate questions about the nature and value of life itself, and so the reflexive focus back on issues of theory has been less apparent in this field than it is in bioethics and environmental ethics. Nonetheless, the rise of international business and the variations in customs regarding gifts, payments and bribes has led to some revival in discussions of cultural relativism, which had been dismissed by many earlier philosophers. And more importantly, the recognition of the role which the profit motive plays in business affairs has led some business ethicists to raise interesting questions about moral motivation, and about their implications for professional business-ethics education.

CONCLUSION

In this broad sweep over the terrain of applied ethics I have sought to demonstrate both the diversity of issues which have been discussed within its various sub-disciplines, and also how the application of different ethical theories allows some progress to be made in resolving these issues. There are many smaller fields within applied ethics which have made significant progress during the period we have been dealing with, but it is beyond the scope of this chapter to discuss these in any detail. Some of these, such as legal ethics, and computer ethics, may well go on to become highly active fields in their own right. In any case, as we approach the end of the twentieth century, what emerges from this brief survey is that the field of applied ethics has transcended its origins in the popular movements of the late 1950s and early 1960s, and has gone on to become perhaps the most flourishing of all branches of philosophy. In doing so, it has added depth and rigour to popular debates about the most pressing issues in our lives, and has set new challenges for ethical theory. It has also developed the interdisciplinary aspect of ethics, which has always been one of philosophy's great strengths. Let me say a little in closing about what I believe the future directions and issues in applied ethics are likely to be.

In environmental ethics, the rise of globalism and the move towards a new world order in the 1990s seems likely to usher in a greater interventionist role for the United Nations in environmental protection,

and since environmental values may diverge from what social justice requires of us in regard to the survival of those in underdeveloped countries, we can expect further discussion of what kinds of trade-offs between justice and environmental values might be justifiable. This issue also looks likely to arise in regard to the international behaviour of transnational corporations. In bioethics, new advances in reproductive technologies may lead to a questioning of women's responsibilities with regard to child-bearing, and the continued march of the patient-rights movement will intensify debates over both the morality of voluntary euthanasia and its possible legalisation. Justice in health-care resource allocation and its implications for patients' rights to adequate access to and delivery of care will be another subject of continued debate, especially in the wake of our ageing populations, and the widespread moves by many governments to further ration healthcare expenditure. Also, progress in gene-mapping coupled with increasing sophistication in pre-symptomatic genetic screening techniques will raise new questions about the desirability and use of such measures both in reproduction and in the workplace. In business ethics, affirmative-action programmes for increasing the participation of women in the workforce will ensure further discussions of justice and fairness in employment policies, and there seems likely to be a greater focus on the moral responsibilities of individual employees in cases where they are acting in an official capacity.

On a deeper level, there are already signs that the renaissance of applied ethics is spawning a satellite industry of philosophers and others engaged in a reflexive critique of the very enterprise of applied ethics, its influences, its methodology and its relation to ethical theory.[5] For example, some writers have recently argued that bioethics is overly dominated by an ideology of individualism, where the value of personal autonomy has too often been allowed to reign supreme over values of beneficence and community (see Callahan [12.10]). There also promises to be further discussion of the distinction between professional and ordinary morality, and of the special rights and duties which an employee's role confers on him. This might have implications for ethical theory, for it might suggest that there are important limitations on the capacity of the traditional partiality/impartiality framework to capture role-based values and obligations (see Blum [12.2]). The focus on professional roles might also pave the way for stronger connections between applied ethics and moral psychology, where questions about the importance of psychological notions such as 'identification' may arise in relation to the concept of a profession as a 'vocation'. Thus, we may begin to see the development of fields such as applied moral psychology.

The importance of psychology for applied ethics may also become apparent in the context of professional ethics education, where after more than a decade of teaching such courses, philosophers are beginning to ask deeper questions about what the aims of such courses are. For example, ought we to be trying to teach doctors and businessmen just to be good reasoners, ought we be trying to develop their sense of conscience, or ought we be aiming to bring about fundamental changes in their characters? These questions cannot be adequately answered without returning to the nature of ethical theory itself, and the role which different theories give to the importance of character development in acting rightly. This has also raised the question of whether there can be any 'moral experts', which some writers regard as an oxymoron, and on which we can expect to see a good deal of further debate in the future.

John Dewey once said that philosophy should be judged by its capacity to meet the challenge of the very conditions which give rise to it. Applied ethics has helped rescue moral philosophy from the intellectual doldrums of the earlier twentieth century, and it is vital to the future of the discipline, for the disengagement of philosophy from practice can only abet the case for the prosecution.[6]

NOTES

1 The idea that the immorality of abortion follows from the moral status of the fetus is largely a twentieth-century phenomenon. Prior to that, purposes was widely regarded as morally permissible, unless sought for certain purposes, such as convenience or sex selection (see Luker [12.20]).
2 This article has probably been more widely anthologized in applied-ethics collections than any other single article, and that alone indicates a measure of its influence.

CHAPTER 13
Aesthetics

George Dickie

INTRODUCTORY REMARK

Aesthetics in the English-speaking world during the twentieth century, with regard to its central problems, falls into three relatively distinct periods: the psychological, the analytic and the contextual.

Until the 1950s, philosophers attempted to resolve aesthetics' central questions—the nature of the experience of art and the nature of art—by using notions of *individual psychology,* notions of what persons do or undergo as individuals. The attempt to define 'art' as the expression of emotion is an example of the use of such a concept. These notions of individual psychology contrast with social notions of what persons do or undergo as members of groups, for example, a person scoring during a game or receiving a degree from a university.

During the 1950s and 1960s aesthetics was impacted by the two strains of analytic philosophy. One strain is of a formal and stipulative sort. The principal figures in this tradition, Monroe Beardsley and Nelson Goodman, have much in common with the philosophers of the psychological period.

The second strain of influence from analytic philosophy derives from Wittgenstein and the ordinary-language philosophers. Philosophers in this tradition deny that 'art' can be defined and generally advocate a non-essentialist approach in aesthetics. These philosophers, unlike Beardsley and Goodman, break sharply with the methods of the psychological period.

From the early 1960s, a number of philosophers have attempted to resolve the central problems of aesthetics with *contextual* theories. Philosophers during this most recent period have done three things. One, they attacked the use of the notions of individual psychology. Two, they ignored or attacked the anti-essentialist approach of the Wittgensteinians. Three, they attempted to describe the experience of art and/or to define 'art' in terms of artworks' contexts.

I shall discuss relatively few philosophers in order to give more complete accounts of their views. Even so, the accounts may not be complete enough to give a full sense of why the theories of these philosophers were so persuasive and influential at the times they were set forth. The Bibliography, structured with the headings used in the text, lists other works related to the views discussed.

THE PSYCHOLOGICAL PERIOD

Aesthetic experience

Edward Bullough

Schopenhauer, in the nineteenth century, was the first to present a full-blown aesthetic-attitude theory, a theory that places disinterested cognition and a detached state of mind at the centre of aesthetic theorizing. This way of theorizing has been enormously influential. Bullough's article on psychical distance (1912 [13.1]) presents the earliest of the well-known, twentieth-century, aesthetic-attitude theories. Bullough, following Schopenhauer, seeks to allay the philosophical fear that people, unless psychologically restrained, will behave practically towards natural scenes and behave towards art in the practical way they behave towards reality.

Bullough claims that to appreciate aesthetic qualities, one must be psychically distanced, a state that puts one 'out of gear with practical needs and ends' and blocks practical thoughts and actions. This state detaches the experience of aesthetic qualities from the rest of experience. Ethel Puffer, Bullough's contemporary with a similar theory, claims that the description of aesthetic detachment 'constitute[s] a theory and a definition of hypnotism'.

Bullough illustrates psychical distance with two cases: someone in a fog at sea and a jealous husband at *Othello*. Supposedly, a distanced person would be able to appreciate aesthetic features because his state of being distanced would prevent him in the one case from being consumed with thoughts of dangers at sea or in the other case with thoughts of an unfaithful spouse. Bullough generalizes from such cases and concludes that all appreciation of aesthetic features requires being psychically distanced. He even claims that being psychically distanced makes stage characters fictional for audience members; gallant, undistanced spectators will attempt to rescue stage actresses from stage villains.

There is a certain plausibility to the view that persons in desperate straits, say, in a fog at sea, must be psychologically restrained in order to appreciate aesthetic features. Most aesthetic situations—looking at a still-life in a museum, for example—are not desperate and do not suggest the need for psychological restraint. It is a mistake to generalize from desperate cases to non-desperate ones. Even in the desperate cases there is no reason to think that psychological restraint occurs or is needed. Worrying about dangers at sea or a wife's suspicious behaviour are just ways of being distracted from the aesthetic qualities of the fog or the action of the play, not ways of being free of psychological restraint. If one's fear or suspicion are allayed, one can attend to aesthetic qualities or a play's action.

That the experience of art requires a detached state has led to the condemnation of certain artistic techniques. One Bullough follower (Dawson [13.2]) condemned Peter Pan's appeal for applause to save Tinker Bell's life because it would supposedly destroy psychical distance and make children unhappy. Should these imaginary, theoretical children be taken seriously? Multitudes of children over the years have responded enthusiastically to the appeal! Incidentally, an actor addressing the audience is an old and common device.

Aesthetic-attitude theorists think that threatening situations, certain theatrical devices, and (if attended to) the intellectual, moral and referential content of art can destroy the detached state that makes aesthetic experience possible. They believe, however, that being psychically distanced can block attention to art's content and allow it to be properly experienced—as the object of aesthetic experience.

David Prall

In *Aesthetic Judgment* (1929), Prall continued the aesthetic-attitude tradition. He begins by declaring that art and the experience of it 'do not contribute to the interested practical and social activities of men' [13.4]. The proper experience of art is of its 'aesthetic surface', colour, sound, spatial order, rhythm, and the like, features that are appreciated independently of anything they are related to. If one attends to the intellectual, moral or referential content of art rather than merely to its aesthetic surface, one 'depart(s) from the… aesthetic attitude'. Prall devotes much space to detailed discussions of aesthetic surfaces. Late in his book, he has second thoughts about art's content. Of literature, he says we experience 'the vast possibilities of life, of human passion and emotion,…and all the thousand relations that men bear to each other'. He then tries to link aesthetic surface to content by 'thickening' aesthetic surface to encompass art's intellectual, moral, and referential content. He first defined aesthetic surface as a perceptual quality experienced as *unrelated* to anything else, but now he wants to *relate* it to what it can represent, describe, state and refer to. Prall ends in a contradiction, trying to give both the content of art and aesthetic surface the weight they deserve.

Jerome Stolnitz

The staying power of the aesthetic-attitude tradition is shown by the fact that Stolnitz claims in 1960 [13.5] that *attending disinterestedly* detaches aesthetic experience from the rest of experience. Stolnitz contrasts disinterested attention with interested attention. He claims, for example, that a critic attending a concert to write a review attends to music *interestedly,* while a person with no such ulterior motive attends *disinterestedly* and has an *aesthetic* experience. The difference between the critic and the non-critic is, however, one of motives, not attention. Motives can affect attention—distract it, focus it—but if the critic and the non-critic attend to the music, despite their motives, their attentions will not be of different kinds. Attending in order to write a review is not a kind of attending, although the prospect of writing a review might focus attention sharply. The critic case and other cases that Stolnitz calls 'attending interestedly' do not involve a kind of attending but simply attending with a particular motive. Some of his cases of 'attending interestedly' turn out to be cases of inattention.

John Dewey

Dewey's theory of aesthetic experience is discussed out of chronological order because it acts as a corrective for the highly influential aestheticattitude theories. Dewey begins *An as Experience* (1934 [13.3]) with a promising account of the experience of art, focusing on the experience of an organism within its environment. In speaking of art *as experience,* he is emphasizing the distinction between what he calls 'the art product', for example, a canvas covered with paint and what he calls 'art', the art product when properly experienced. Dewey understands the experience of art to be a development out of ordinary experience, and it is not seen as detached from life.

Dewey envisages the experience of art as aesthetic experience, which he sees as a development out of the aesthetic experience of natural things. He explicitly rejects the conception of aesthetic experience that flows from Schopenhauer through Bullough to Prall. He sees aesthetic experience not as detached and contemplative but simply as experience with a substantial degree of internal coherence; it is for him the kind of thing we note as being '*an* experience', experience in which the elements cohere into a consummately unity and stand out from the flow of experience.

Dewey does not say much about the referential aspects of art. Reference is troublesome for aesthetic-attitude theorists because features of art that refer from *inside* a supposedly detached and self-contained

aesthetic experience to something outside it are thought of as disruptive of aesthetic experience. Referential features of art are not a problem for Dewey. The elements of aesthetic experience, for him, cluster together but they are not detached and isolated from the rest of experience.

The philosophy of art

George Santayana

While Santayana's *Reason in Art* (1905 [13.11]) is perhaps the earliest of the twentieth-century philosophies of art in English, its philosophical theses are neither developed nor argued for. The book is largely devoted to art criticism.

Santayana begins with a discussion of the place of art within his philosophical naturalism. By 'art' he means technology. Santayana then moves to the *fine* arts, defining them as 'productions in which an aesthetic value is or is supposed to be prominent'. He notes that fine art 'has many non-aesthetic functions and values', a thesis that recurs frequently to emphasize the continuity of art with life. Santayana's definition and his repeated thesis are never defended, and the holders of opposing views are not mentioned. The philosophical topics appear merely to be prologue to the art criticism.

Clive Bell

Bell's *Art* (1914 [13.6]) presents what is generally regarded as a formalist philosophy of visual art. The foundation of Bell's theory is 'the aesthetic emotion', an emotion distinct from the ordinary emotions of life such as pity and fear. All *sensitive* persons, he says, can experience and identify this emotion. He then asserts, 'The objects that provoke this emotion we call "works of art".' The next step is to discover what works of art have in common as their essential quality. He assumes that only *one* thing causes aesthetic emotion. His answer is that the essential quality of art is *significant form*. He means by 'form' the relations of line and colours in visual art, and by 'significant form' he means the sub-set of these forms that evoke aesthetic emotion. Bell denies that representation as such in art has any artistic value.

Bell's view is not really a philosophy of art because it excludes many objects ordinarily viewed as works of art. He asserts that the great bulk of paintings, statues and the like are not works of art; they do not provoke aesthetic emotion. Another reason his theory is not a philosophy of art is that he says significant form, art's essential quality, sometimes occurs in natural objects—he cites a butterfly wing. Bell's class of works of art includes objects that no one regards as art!

Bell's theory is really an instrumentalist theory for the *evaluation* of visual art, that is, a theory about what in visual art is instrumental in producing valuable experience (aesthetic emotion). It seems unlikely that there are aesthetic emotions, although valuable experiences are produced by art. The psychological content of Bell's theory is suspect, but as an evaluational theory, its instrumentalist structure is promising.

John Dewey

The expressionist theory of art arose in the nineteenth century and remained a powerful influence well into the present century. In *Art As Experience* (1934 [13.8]), Dewey presents one of the earliest of the twentieth-century expressionist theories. He launches into an account of art as the expression of emotion without any argument, seeming to regard it as obviously true, as did many others of the time. Dewey distinguishes the mere

venting of emotion from the expression of emotion, the latter requiring the conscious ordering of a medium. This distinction allows him to exclude some emotional behaviour (venting) from the domain of art.

Although he writes at length about expression and expressive objects, it is not clear whether he identifies the expression of emotion with art, or whether he thinks expression is just a necessary condition of art.

Art frequently has expressive qualities, but affirming the expression theory of art is another matter entirely. The expression theory has received effective criticism in recent years; few today believe that every work of art is an expression of emotion of its creator or that every expressive quality of a work of art is an actual expression of an emotion.

Dewey claims that the expressiveness of art entails that each art form is a language for a kind of communication. Whether every art form is a language and a means of communication is very doubtful and that this follows from being expressive is even more doubtful.

Despite the difficulties of Dewey's theory of art, much of what he has to say about expression and expressive qualities is quite sound. He also shows a very considerable knowledge of the arts, especially the visual arts.

R.G.Collingwood

In *Principles of Art* (1938 [13.7]), Collingwood, also following the expressionist tradition, claims that what he designates 'art proper' is *identical* with the expression of emotion. He gives an argument of sorts to support his claim: he is making clear how words are used in English. The meanings of 'art (proper)' and 'craft' are completely distinct. A craft object is a preconceived product produced by the application of a skill to a raw material, while art is a completely spontaneous, unplanned thing. Crafts may be involved in the conveying of art to its audience, but art and craft are distinct.

Collingwood asserts without argument that 'Art has something to do with emotion', i.e. that art and emotion are necessarily connected. He assumes two possibilities: something can express emotion or something may be designed to evoke emotion. The latter would involve a preconceived end (the evoking of emotion) and would, therefore, be a craft product. Expressing emotion is spontaneous. He concludes that art, which he believes to be spontaneous and unplanned, is identical with the spontaneous phenomenon of expressing of emotion. Even if his premises were granted and it were agreed that art is necessarily connected to the expression of emotion, it does not follow that art is *identical with* the expression of emotion.

Collingwood's conclusion appears to make rages and the like into art. He tries to avoid this difficulty by saying that such behaviours are not art because they are betrayals rather than expressions of emotion, which, he claims, are controlled actions. This move narrows the ordinary meaning of 'expression of emotion'.

Collingwood claims people sometimes confuse art proper with the crafts he calls 'magical art' and 'amusement art'. Magical art, for example, patriotic and religious art, is craft because it is designed to evoke emotions to sustain certain life activities, and amusement art is craft because it is designed to evoke emotion for enjoyment. He suggests that because they were designed to evoke emotion in Elizabethan audiences, Shakespeare's plays are not art!

The expression of emotion is an act of the imagination in that it brings something into consciousness. Collingwood takes this to mean that an act of expression, i.e. art, is imaginary and takes place in the mind only and is purely mental. Thus, for Collingwood, paintings, statues and the 'noises' musicians make are not art; they are craft objects that enable others to re-create art in their own minds. This means that what are ordinarily understood to be artworks are understood by Collingwood to be craft objects, and that what are

ordinarily understood to be the conceiving of and the understanding and appreciation of art are understood by Collingwood to be artworks.

There are several difficulties with Collingwood's theory. First, it excludes many things that almost everyone thinks of as art, namely works with no emotional content. His response is that a product of serious activity always retains an element of emotional expressiveness. He cites Eliot's *The Waste Land* as an example of art. This work is the result of serious activity and has emotional content, but it is not clear that a serious activity must always have an emotional element. It is also not clear that the creation of art is always a serious affair. Second, his theory is also flawed if, as he apparently thinks, it excludes Shakespeare's plays from the domain of art. The third difficulty is that his *identification* of art with the expression of emotion would turn into an many things that no one thinks are an. When a parent says in a controlled but exasperated tone, 'Turn off the television and do your homework', that parent is expressing emotion but not thereby creating a work of an.

Suzanne Langer

In *Feeling and Form* (1953 [13.9]), Langer, continuing the focus on emotion, defines 'Art' as 'the creation of forms symbolic of human feeling'. She is claiming that every artwork *as a whole* is a symbol. She explains that art symbolizes by abstraction; for example, 'Music is a tonal analogue of emotive life.' Art symbolizes by abstract resemblances. She is not talking about the resemblance involved in representation; both non-objective and representational art allegedly symbolize. Art for Langer is an iconic symbol, i.e. a symbol that resembles what it symbolizes. The main difficulty with her account is that it ignores the *conventional* basis of symbols. Iconic symbols do not function merely in virtue of a resemblance; as all symbols must, they have to be *established* as signifying what they do. In *Problems of Art* (1957 [13.10]), Langer accepted this criticism which reduces her theory to the view that art is the creation of forms that resemble human feeling.

Does every work of art resemble human feeling? Some music is a tonal analogue of emotive life and some visual art does resemble human feeling. Many works of art—non-objective and representational —however, just do not resemble human feeling; Langer overgeneralizes from what is true of some cases.

General Comment

The central ideas of all the foregoing theories are notions of individual psychology. Psychical distance and disinterested attending would both be phenomena that individuals do or undergo as individuals. Aesthetic surface, aesthetic qualities and significant form are or would be objects of perception, and perceptual discrimination is an ability that individuals exercise as individuals. Dewey's conception of the aesthetic experience as *an* experience of consummatory unity is something an individual undergoes as an individual. The expression of emotion *is* something an individual does as an individual, and aesthetic emotion *would be* a kind of thing that an individual would do as an individual. Langer's basic notion—noting resemblance—is something individuals do as individuals. Two of these notions fall under the category of awareness, two fall under the category of affect, and six fall under the category of perception.

THE ANALYTIC PERIOD

The experience of art

Monroe Beardsley

Beardsley's *Aesthetics* (1958 [13.12]) describes its subject as 'metacriticism', the analysis of concepts involved in describing, interpreting and evaluating art. Beardsley begins by trying to characterize the proper objects of criticism, which he calls 'aesthetic objects' (the aesthetic aspects of artworks). His focusing on *aesthetic* objects shows that he is continuing the earlier tradition of focusing on the aesthetic aspects of art. His first step is to argue that artists' intentions are distinct from artworks and, thus, not aspects of their aesthetic objects. His second step is to distinguish between the *perceptual* aspects of art (those perceptible *under the normal conditions for experiencing art*) and the *physical* aspects of art (those aspects not perceptible under normal conditions). This second step is supposed to eliminate certain aspects of art that are not proper objects of criticism—(1) physical aspects such as sound waves and light waves that are not experienced at all and (2) aspects such as the colour of the back of a painting and the actions of unseen stage-hands that are not experienced under normal conditions. The second step does not eliminate perceptible things such as print marks used to inscribe a poem and the colour of a painting's frame, but Beardsley's third step is supposed to do this. This third step—the consideration of the properties of various perceptual domains—concludes with the definitions of 'visual design', 'musical composition' and 'literary work', which are supposed to eliminate the remaining improper elements. I shall consider only 'visual design', which is defined as 'a bounded visual area containing some heterogeneity'. The colour of a painting's frame is *not,* however, eliminated by the third step; it is perceptible and is part of *a* bounded, heterogeneous visual area, and there are analogous problems in other visual-art cases. Moreover, the perceptual/physical distinction would eliminate important aspects of some aesthetic objects—the non-perceptible meaning of literary works, for example. The second and third steps of Beardsley's account of aesthetic objects both fail; his understanding of the objects of criticism throughout his book is not, however, hampered by this. The initial question of whether artists' intentions are relevant to interpretation is still a hotly debated topic.

Beardsley concludes that *the* function of aesthetic objects is the production of aesthetic experience, and he works out an account of such experience that owes something to Dewey and something to Bullough and others. According to Beardsley, every aesthetic quality (gracefulness, delicacy, and the like) of an aesthetic object is an instance of one of three primary aesthetic properties: unity, intensity or complexity. These three primary properties when perceived can supposedly *cause* a person's experience to have certain affects, namely, to be unified, intense and complex. Aesthetic experience, thus conceived, consists of (1) the experience of the three primary perceptual properties of aesthetic objects and (2) the affects (felt unity, intensity and complexity) that are caused by these primary perceptual properties. In addition, he alleges that aesthetic experience has a *detached* nature deriving from its unity which supposedly insulates and detaches the experience from things outside it. Beardsley agrees with Dewey that aesthetic experience is highly unified. He, however, accepts Bullough's contention that aesthetic experience is detached, a view Dewey explicitly rejects.

Beardsley concludes that any content of art that refers to something outside the aesthetic experience—say, its cognitive or moral content—is nullified by the *detached* nature of aesthetic experience. On his view, only the non-referential aspects of art—the aesthetic qualities of unity, intensity and complexity—contribute to aesthetic experience. Because Beardsley conceives of aesthetic experience as detached, his theory has no

way to account for the functioning of whatever referential content art has. This signals that the notion of the experience of art as detached is flawed; Beardsley should have followed Dewey more closely.

Nelson Goodman

In *Languages of Art* (1968 [13.16]), Goodman agrees with Beardsley that the function of art is to produce aesthetic experience, but his conception of such experience is radically different. Goodman claims that the aesthetic experience of art is not a matter of the appreciation of aesthetic qualities, is not detached and is cognitive in nature. He, thus, breaks sharply with the tradition followed by Bullough, Prall, Stolnitz and Beardsley.

Goodman claims that every work of art is a symbol that symbolizes by description, representation, expression, exemplification or some combination of the four. He asserts that the purpose of symbols and, hence, art, is cognition and that art is to be evaluated by how well it serves its cognitive purpose. Art's cognitive purpose is served by 'the delicacy of its discriminations…the way it works in grasping, exploring, and informing the world…how it participates in the making, manipulation, retention, and transformation of knowledge'.

Many works of art are symbolic, but are they all? In the section on the evaluation of art at the end of this article (pp. 421–5), it will be argued that some artworks (most non-objective art and instrumental music) are not symbolic.

Frank Sibley

Sibley's 'Aesthetic Concepts' (1959 [13.17]) began an important discussion of aesthetic qualities and has generated a large literature. He begins his article by distinguishing aesthetic terms, concepts and qualities from non-aesthetic terms, concepts and qualities. 'Red' and 'square' are examples of non-aesthetic terms, and redness and squareness are examples of non-aesthetic qualities. The application of non-aesthetic terms and the discernment of non-aesthetic qualities requires only 'normal eyes, ears, and intelligence'. 'Fiery' and 'delicate' are examples of aesthetic terms and fieriness and delicacy are examples of aesthetic qualities. The application of aesthetic terms and the discernment of aesthetic qualities requires more than normal perception and intelligence, they require 'the exercise of taste, perceptiveness, sensitivity'. For Sibley, an aesthetic term is *identified* as one whose application requires an exercise of taste, and an aesthetic quality is *identified* as one whose discernment requires an exercise of taste. For Sibley, terms are not aesthetic or non-aesthetic as such; some terms may always be used aesthetically, but some may be used aesthetically and non-aesthetically, depending on context. Thus, for Sibley, taste is the most basic category; taste identifies which use of a term is an aesthetic use and identifies which features are aesthetic features.

Aesthetic qualities, he claims, depend on non-aesthetic features. What is the nature of this dependence relation? Non-aesthetic qualities such as squareness have necessary and sufficient conditions, in this case, having four equal sides and four right angles. Sibley denies that aesthetic qualities have necessary and sufficient conditions because, for example, one object is delicate because of one set of non-aesthetic features and another object is delicate because of a different set of non-aesthetic features. In addition, he also denies there are *logically sufficient* conditions for aesthetic qualities. In a particular case of, say, delicacy, its non-aesthetic conditions do suffice to produce delicacy, but the occurrence elsewhere of those same non-aesthetic conditions is not, he claims, always sufficient to produce the occurrence of delicacy. It is true that certain non-aesthetic features may count only towards and not against the occurrence of a certain aesthetic quality, but the occurrence of such non-aesthetic features cannot guarantee the occurrence of a

particular aesthetic quality. Also, some aesthetic qualities may be governed *negatively* by non-aesthetic conditions; for example, a painting consisting only of pale pastel colours could not be garish. Sibley's view is that aesthetic qualities depend on non-aesthetic features but that they are not positively condition-governed and that, consequently, the applications of aesthetic terms are not rule-governed.

That there are aesthetic qualities and that they depend on non-aesthetic qualities is widely accepted. Many also accept Sibley's contention that aesthetic qualities are not condition-governed. The chief difficulty with Sibley's view is his notion of taste and its use in identifying what counts as an aesthetic quality. This difficulty is brought out by Ted Cohen (1973 [13.14]) who focuses on the perception of aesthetic qualities in simple cases. Consider the perception of *gracefulness* in a female ballet dancer's movements or the *awkwardness* in the walking of a year-old child. Cohen asks, does it take anything other than normal eyes and intelligence to note these two aesthetic qualities? He answers in the negative, and if that is so, then taste does not identify what counts as an aesthetic quality in simple cases. Perhaps to try to forestall this argument, Sibley claimed in 'Aesthetic Concepts' that virtually everyone can exercise taste to some degree in some domains. But if normal sense faculties and intelligence *and* taste are almost always present at the same time, how can we know in simple cases whether it is normal perceptive capacities or taste that discerns aesthetic qualities. Or, consider complicated cases in which one person discerns and another person fails to discern an aesthetic quality. Perhaps the person who fails to perceive does so because his normal perceptive capacities are a bit limited and the person who does perceive has slightly greater normal perceptive capacities. It does not seem that we can be assured in either simple or complicated cases that there is taste in Sibley's sense, and, hence, we cannot be assured that Sibley has a way of identifying what counts as an aesthetic quality.

The philosophy of art

Paul Ziff

Ziff in 'The Task of Defining a Work of Art' (1953 [13.25]) was the first to apply the anti-essentialism that began sweeping through philosophy in the 1950s to the philosophy of art. He claims usage of the expression 'work of art' shows there is no necessary condition for being art, not even being an artifact. A naturally formed stone that looks like a sculpture and is worth contemplating can, for example, be said to be a work of art. This is supposedly so because the stone *sufficiently* resembles a characteristic case of art. The many different usages of 'work of art' supposedly show that many different sufficiency definitions are possible. Each such definition has a characteristic case, say, Rembrandt's *Night Watch,* and anything that sufficiently resembles it is a work of art. Even if a characteristic case is an artifact, members of the class of objects it generates do not need to be artifacts, they need only to resemble the characteristic case sufficiently. No rule can be given, he says, as to what constitutes sufficient similarity. Ziff says that novels, poems and musical compositions are so different from paintings that they cannot be included in the class of objects that sufficiently resembles *Night Watch*. They can, however, be called works of art because they sufficiently resemble other characteristic cases. On Ziff's view, there are as many different definitions of 'work of art' as there are different uses of the term.

Morris Weitz (1956 [13.24]) and William Kennick (1958 [13.23]), influenced by the anti-essentialism of the period, drew similar conclusions about the definition of 'art'. These three articles brought attempts to define 'art' to a virtual halt during the analytic period. Sibley's claim that aesthetic qualities are not condition-governed is in the same anti-essentialistic tradition that Ziff is in.

A naturally formed stone *can* be said to be a work of art and a class *can* be constructed that includes sculptures plus such a stone. Should these two facts cause philosophers to abandon the traditional claim that artifactuality is a necessary condition for art? I think not. Philosophers of art need take no interest in such usage or in a class so constructed, because they have always theorized about a class of human artifacts. Artifactuality is a built-in feature of their activity; their real problem has always been to discover the other defining feature or features of these artifacts. Moreover, there is solid agreement about which artifacts belong to the class of objects they theorize about— paintings, poems, plays, and so on.

Nelson Goodman and Monroe Beardsley

Because of the powerful influence of anti-essentialism, theorizing about art was not a popular activity among philosophers in the analytic period. Whether Goodman's claim that all works of art symbolize is put forth as a partial definition of 'art' or simply as a universal generalization is unclear; either way his claim fails because of his theory's inability to deal with non-objective art and instrumental music.

Beardsley did not turn his attention to the definition of 'art' until 1979. He writes then, 'an artwork can be usefully defined as an intentional arrangement of conditions for affording experiences with marked aesthetic character' [13.21]. This definition, which continues Beardsley's emphasis on aesthetic features, was put forth in explicit opposition to contextual theories of the late 1960s and the 1970s that take the domain of art to include Duchamp's *Fountain,* dadaist works generally and similar artworld creations—works that have little or no capacity to afford aesthetic experience as Beardsley conceives it. Beardsley's ruling out of such avant-garde works in order to make aesthetic considerations *necessary* is a stipulatory move characteristic of his wing of analytic philosophy. Also, since Beardsley's definition of 'artwork' depends on his notion of detached aesthetic experience, his definition inherits all the difficulties involved in the idea of detachment.

General Comment

Many philosophers of the analytic period continued to try to solve the problems of aesthetics with concepts of individual psychology. Beardsley's use of *perceptibility* and the *properties of perceptible domains* to try to distinguish aesthetic objects are uses of such concepts. Perception is an activity a person does as an individual. Similarly, his notion of aesthetic *experience* with its content of aesthetic qualities and their affects and its detachedness is something a person undergoes as an individual. Goodman's claim that the aesthetic experience of art is an *experience* of the reference of symbols involves something persons undergo as individuals. Ziff's notion of *noting sufficient resemblance* is a notion of something that a person does as an individual. Finally, Sibley's attempt to distinguish aesthetic from non-aesthetic features on the basis of what *normal eyes, ears and intelligence* can discern and what *taste* can discern is clearly the use of notions of capacities persons exercise as individuals.

THE CONTEXTUAL PERIOD

Introductory Remark

Contextualist theorists break sharply with the traditions of the two earlier periods. One or more of the three hallmarks of the contextual period—the rejection of concepts of individual psychology, the rejection or ignoring of the prevalent anti-essentialism and the use of the contexts in which artworks are embedded—were

enunciated independently in five articles by four philosophers during the period 1962–5. In 'Is Psychology Relevant to Aesthetic?' (1962 [13.27]), I claimed that the thought and behaviour of art's audiences are not controlled by the psychological phenomenon of psychical distance but by rules of artwork contexts. In 'Aesthetic Essence' (1965 [13.26]), Marshall Cohen attacked a number of individual psychology notions, including psychical distance as a controller of spectator behaviour. Concerning the contextual control of behaviour, Cohen mentioned the *learning* of how artworks are to be experienced. In 'The Myth of the Aesthetic Attitude' (1964 [13.28]), I attacked Bullough and the aesthetic-attitude theories of Jerome Stolnitz and Eliseo Vivas. In 'The Artworld' (1964 [13.37]), Arthur Danto, ignoring the prevalent anti-essentialism, set forth the first contextualist account of the nature of art. In 'Family Resemblances and Generalization concerning the Arts' (1965 [13.48]), Maurice Mandelbaum directly attacked the anti-essentialism of Ziff and Weitz. Mandelbaum also recommended a contextual approach to generalizing about art without attempting to work out the details.

The positive insights of these five articles were developed along two lines: accounts of the contextual control of experiences of art and accounts of the contextual nature of art.

The experience of art

Marshall Cohen and George Dickie

The criticisms Cohen and I made of the mechanisms of individual psychology supposedly involved in the proper experience of art were incorporated into my earlier criticisms of aesthetic-attitude theories and of Beardsley's account of aesthetic object and require no further comment.

Aesthetic-attitude theorists claimed that a particular psychological state (variously described) controls the thought and behaviour of the experiencers of an; jealous husbands can attend to *Othello* if psychically distanced, children are disturbed by Peter Pan's request for applause because it destroys their psychical distance, and gallant spectators do not attack stage villains if they are psychically distanced. If, however, there are no such psychological states, what does control thought and behaviour in the face of artistic phenomena?

Samuel Johnson's eighteenth-century answer was 'The truth is, that the spectators are always in their senses, and know, from the first act to the last, that the stage is only a stage, and that the players are only players' [13.30]. One's knowledge of the nature of an artistic activity, alluded to by Cohen [13.26] and myself [13.27], is what controls spectator's thoughts and actions.

A more extensive, if somewhat piecemeal, account of the contextual control of the experience of art is found in my *Art and the Aesthetic* (1974 [13.29]). Consider the cases of the attacker-spectator and Peter Pan's appeal. There is a general *rule* or *convention,* understood by all, that audience members do not interact with a play's action. A gallant spectator who attacked a stage villain would be someone who flouts this convention out of ignorance of theatre art or because of insanity. Such a spectator would not be someone who had lost the aesthetic attitude, although he could be someone who had lost his mind. When Peter Pan appeals for applause, it signals that the usual convention is being set aside and that a different convention is being put in place. Children catch on right away that there has been a convention shift, even if some aestheticians don't. A convention is by definition something that can be done in more than one way, and different plays have different conventions governing spectator participation. Reflection will reveal that there are many conventions involved in the presentation of the arts to their publics. Although the jealous-husband-at-*Othello* case does not involve being in or losing the aesthetic attitude any more than the other two cases

do, it does not directly involve theatre convention either; the husband is just someone whose thoughts of his wife may cause him not to pay attention to the play.

Aesthetic-attitude theorists claim that being in the aesthetic attitude reveals which characteristics of art belong to the aesthetic object of works, i.e. which characteristics are to be appreciated and criticized. Beardsley makes a similar claim for perceptibility and other criteria. Both claims fail. What does direct attention to aesthetic objects of works of art? It is the background knowledge of theatre—its nature and conventions—that isolates the aesthetic objects of plays. The situation is the same in the other arts; it is the background knowledge of painting, literature, and the like, not the functioning of mechanisms of individual psychology, that guides people to the characteristics of art that are to be appreciated and criticized.

Kendall Walton

I turn from the question of what controls those who experience art to the consideration of the aesthetic content of art. Sibley concluded that aesthetic qualities depend on non-aesthetic qualities. In 'Categories of Art' (1970 [13.31]), Kendall Walton, Sibley's student, goes a step further, concluding that the aesthetic qualities of *artworks* depend also on the historical contexts of the artworks. He challenges the view that artworks' aesthetic qualities can be discovered by *merely* perceiving them. Walton notes that artworks are perceived as members of categories — as statues, as paintings, as cubist paintings. Each category has *standard* features, those features that make for belonging to that category. Flatness, motionlessness and the use of shapes are among the standard features for the category of painting. Flatness, motionlessness and use of *multiple squarish* shapes are standard features for the category of cubist painting. Being the colour of marble and not representing the body from a point just below the shoulders are standard features for Roman marble busts. Each category also has *variable* features, features that may be different in different works of the category and which have nothing to do with works belonging to a category. *Particular* shapes and colours are variable for the category of paintings, and *particular* colours are variable for the category of cubist paintings. A feature is *contra-standard* for a category if its presence tends to disqualify a work with that feature from the category. A protruding, three-dimensional object would be contra-standard for the category of paintings.

Categories are involved in visual representation. Standard features are ordinarily irrelevant to representation. A painting's being flat and motionless does not prevent it from representing a three-dimensional object in motion. A Roman bust's being made of white marble and not representing the body from just below the shoulders does not make it portray a very pale person who has been severed at the chest. In contrast, variable features *are* involved in representation—the particular shapes and colours of a painting and the particular shapes of a Roman bust represent by means of resemblance.

Categories are involved in determining the *aesthetic* qualities of artworks. A person unfamiliar with the category of cubist painting might find a cubist painting to have the aesthetic quality of jumbledness. He would be looking at the painting under the category of ordinary representational painting, taking its multiple squarish shapes to be variable and representative of, say, a rather chopped-up looking man. A person looking at the painting under the category of cubist painting, taking its multiple squarish shapes to be standard, would see the painting to be just a representation of a man and not jumbled. Moreover, when the repeated squarish shapes are taken as standard and not as representative, their repeatedness may impart an aesthetic quality of orderliness to the surface of the painting.

An artwork can thus have one set of aesthetic properties when viewed as a work in one category and another set when viewed as a work in another category. An artwork's *actual* aesthetic properties are the

ones it is perceived to have when it is perceived *correctly*. How is correctness determined? Walton cites four considerations that count towards determining correct categories.

1 An artwork's having a relatively large number of features standard and few or no contra-standard features for a category make for that category's being correct for the artwork. This condition alone does not suffice; certain works of Cézanne would appear to fit into the category of cubist paintings, but they are not cubist paintings.
2 An artwork's being better when perceived in a particular category rather than in others makes for that category's being correct. The two conditions do not suffice; given a mediocre work that obviously fits into a particular category, it would always be possible to invent a new, outlandish category in which the work would be better.
3 An artwork's fitting into a well-established category makes for that category's being correct. This historical condition will not resolve every problem; important, new works and categories are sometimes invented—Walton cites Schoenberg's twelve-tone music.
4 An artwork's being intended by its maker to be perceived in a category makes for that category's being correct. This historical condition will not resolve every case; artists' intentions are frequently unknown or unclear.

These conditions establish the correct category for many cases but leave undecidable cases. Walton cites Giacometti's sculptures. If they are seen as sculptures, their limbs look frail and wispy. If they are seen as thin metal sculptures, their limbs do not look frail but just expressive. It is not incorrect to perceive the sculptures either way, and thus it cannot be said what the actual aesthetic properties of the works are. Walton does not regard the existence of undecidable cases to be a bad thing.

The philosophy of art

Arthur Danto

Danto followed 'The Artworld' [13.37] with a series of publications. In these publications, Danto begins by conceiving of an artwork and a non-an object that are visually indistinguishable: Duchamp's *Fountain* and a urinal that looks exactly like it, Rembrandt's *The Polish Rider* and a randomly produced non-art object that looks exactly like it, and so on. Such pairs show that it is not its exhibited, perceptible properties that make something art but a context in which it is embedded.

What was new for twentieth-century aesthetics is that the context that Danto envisaged involves *cultural* concepts rather than notions of individual psychology. In contrast, the expression theory envisaged artworks embedded in a context involving the expressing of an emotion.

Danto gives two different accounts of the cultural context that makes something an artwork. In 'The Artworld' he claims that the prevailing *art theory* provides the context that enables artifacts to be works of art. Once the prevailing, enabling theory was the 'Imitation Theory of Art', and now it is what he calls the 'Real Theory of Art'. In 'Artworks and Real Things' (1973 [13.38]), Danto claims *being a statement* makes something an artwork—this alleged art-making context is a linguistic one rather than an art-theory one. In 'The Transfiguration of the Commonplace' (1974 [13.39]) and in his book of the same name (1981 [13.40]), he continues to speak of a linguistic context, claiming that being *about* something and therefore being *subject to interpretation* is what makes something an artwork.

At the beginning of his third article [13.39] he makes a less than universal claim about aboutness. Danto conceives of an artist who exhibits a square of primed canvas he entitles *Untitled* and who declares that it is not about anything. Danto then says,

> Our artist has produced something which is of the right sort to be about something, but in consequence of artistic fiat it happens only not to be about anything…. Artworks may indeed reject interpretation, but are of the right sort to receive them.

Danto is saying that artworks are the sorts of thing that are typically about something but that it is possible for artworks not to be about anything and thus not interpretable. Aboutness is not, therefore, a universal property of artworks. However, at the end of this article, Danto writes,

> As for the somewhat empty works [including presumably *Untitled*] with which I launched this discussion, I have this to say, what they are about is aboutness, and their content is the concept of art. [13–39]

Danto originally claimed that the artist's declaration that *Untitled* was not about anything made it not about anything. Is *Untitled* about aboutness or is it merely 'the right sort to be about something'? In any event, there is no reason to think that many present-day non-objective paintings are about anything, even if some non-objective paintings such as *Untitled* are about something. Retreating to an earlier time, a typical piece of eighteenth-century instrumental music is not about anything either. There appear to be counter-examples to Danto's claim, if it is the claim that all artworks are about something. He may, however, be making the weaker claim that artworks are the sort of thing that *can be* about something.

Even if all artworks were about something and subject to interpretation, Danto would not have a theory that picks out only the class of works of art. Statute laws, directions for assembling a bicycle and many other non-artworks are about something and are subject to interpretation.

Danto appears to claim that artworks are about something and subject to interpretation; these two ways of talking about *meaning* point in different directions. Saying that an artwork is about something points to an artist who creates an object. Saying that an artwork is subject to interpretation implies that its meaning can be understood by members of an artworld *public*. Although some earlier philosophies of art have referred to art's audience as necessary, Danto's was one of the first to indicate that the necessary audience is an artworld public—a cultural phenomenon. Danto is right that artworks are bearers of meaning embedded in a context or framework between artist and public; he is not right if he thinks the meaning borne is always aboutness.

Maurice Mandelbaum

In 'Family Resemblances and Generalization concerning the Arts' [13.48], Mandelbaum criticizes the view of Weitz and others that 'art' cannot be defined. These philosophers had claimed that artworks have no common characteristic, just overlapping similarities; they called the concept of such a class a 'family-resemblance' concept. Mandelbaum notes that *family* resemblances literally occur among persons with a genetic tie; no one of the overlapping visible resemblances exhibited by family members may be shared by all, but all *family* members share an underlying genetic connection. He suggests that the defining features of art may be discoverable, if instead of looking at the perceptible characteristics exhibited by art, one looks

for underlying relational features, namely, relationships that can be discovered among art object, artist and contemplator. Mandelbaum does not attempt such a theory.

George Dickie

Danto revealed art's cultural context and implied that artists and publics are necessary. Mandelbaum recommended attention to the relationships among art object, artist and contemplator. Guided by these ideas, beginning with 'Defining Art' (1969 [13.42]) and concluding with *Art and the Aesthetic* (1974 [13.29]), I worked out the earlier of the two versions of the *institutional* theory of art. In both versions 'institutional' refers to a cultural *practice*—the set of practices involved in producing the various arts—not an organization of persons that has meetings and acts as a group. In the earlier version, an artwork is defined as an artifact that has had candidacy for appreciation conferred on some of its features (its aesthetic object) by some person or persons who act on behalf of the artworld. I maintained that artifactuality could be achieved in the usual way by working with artistic media. I, however, also maintained it could be conferred on an object; I argued that *Fountain* and such works had had artifactuality conferred on them. According to this earlier version of the theory, to be an artwork is to have acquired a status within a rather formally described institutional structure as the result of an artist's or artists' action.

Ten years later in response to the criticism of Beardsley and others, I presented in *The Art Circle* (1984 [13.43]) a greatly revised and more informal institutional theory. I dropped the formal terminology—*acting on behalf of* the artworld and *conferring* of candidacy and artifactuality —and spoke instead of artists working with their materials against the background of the artworld. Also, in *The Art Circle,* instead of defining just 'art', I gave five interrelated definitions, which provide the leanest possible account of the new version.

> An artist is a person who participates with understanding in the making of a work of art.
>
> A work of art is an artifact of a kind created to be presented to an artworld public.
>
> A public is a set of persons the members of which are prepared in some degree to understand an object which is presented to them.
>
> The artworld is the totality of all artworld systems.
>
> An artworld system is a framework for the presentation of a work of art by an artist to an artworld public.

Note that the last definition makes use of the key terms of the other definitions. The definitions are obviously circular—but not viciously so. Circularity is vicious if one is confronted with a circular account of an alien phenomenon of which one is ignorant. The making and appreciating of art, however, is a cultural phenomenon people are involved with from early childhood; the meanings of the key terms of this interconnected system are well known to everyone. We learn about the concepts of this circular set at the same time; one cannot be taught what a work of art is without being taught what an artist, an artworld public and an artworld system (painting, theatre, and the like) are. None of the key notions serves as a foundation for the rest. (By the way, new artworld systems—for example, happenings—are introduced from time to time.)

The institutional definition of 'work of art' is value-neutral—it covers good, bad and indifferent art. The definition of 'art' has to be about all art, not just valuable art or any other sub-set. What artworks have in common is not value but a *status* within the artworld. By the way, the definition of 'work of art' refers to

the basic or primary items presented to artworld publics, not things like playbills, programme notes, and the like which are parasitic on the primary items.

The notion of *understanding* is used in the definitions of 'artist' and 'public'. What both an artist and a member of an artworld public understand is the general idea of art, i.e. that they are engaged in a certain, specific kind of activity. What in addition an artist must also understand is the particular medium in which he is working. Also, the definition of 'work of art' speaks of an artifact *of a kind* created to be presented to an artworld public. The 'of a kind' qualification is made in order not to exclude works of art that are created but, for whatever reason, are never presented.

The institutional theory does not mention certain highly valued features of art—representational, expressive, symbolic and aesthetic features. Important as such features are, when they occur in art, they are not universal features of art and, hence, cannot be defining characteristics. Art is a cultural invention that can incorporate all these features and others, but it does not have to involve any of them.

In *Definitions of Art* (1991 [13.41]), Stephen Davies surveys and analyses theories of art presented since the 1950s; he distinguishes between functional and procedural accounts of art. Functional accounts see art as having a specific function—to express emotion, to produce aesthetic experience, to be about something. The institutional account of art is procedural, i.e. defines 'art' in terms of certain cultural procedures. A procedural theory places no limits on what artworks can function to do, but it claims that none of the functions is universal and defining. Davies also discusses a number of recent definitions of 'art' which in one way or another resemble the institutional theory; he characterizes these theories as *historical, narrative* or *intentional*. Works on these theories and on theories not discussed by Davies are listed in the Bibliography: see T.Diffey [13.44]; J.Margolis [13.49]; T.Binkley [13.32–3]; J.Levison [13.47]; M.Eaton [13.45]; L.Krukowski [13.46]; and N.Carroll [13.34].

INTERPRETING AND EVALUATING ART

Interpretation

Monroe Beardsley

Beardsley argues that to interpret an artwork is to understand its meaning. Interpreting the words, sentences, representations, motives of characters, and the like in artworks is not different from understanding parallel things in real life.

Suppose in a conversation about where people are from, someone says, 'He was born in a small town in the state of New Jersey, USA.' The hearer will easily understand (i.e. correctly interpret) the remark. Similarly, there are cases in which it is understood without a doubt what someone's motive is. Some statements and actions are easy to interpret. If someone utters a truly ambiguous sentence, the hearer can not understand it because it does not have *a* meaning, although it suggests two or more meanings; the remark will not be interpretable. If someone utters a garbled string of words, the utterance cannot be interpreted either. Similarly, sometimes we have no idea what motivates a person's action.

The interpretation of artworks, on Beardsley's view, parallels interpretation in real-life situations. A novel that begins 'He was born in a small town in New Jersey, USA' and continues with sentences that are just as straightforward could be easily understood, i.e. easily interpreted. Critics and philosophers, however, are not usually concerned with simple and easily interpreted works but with questions about complicated cases such as 'Is there a hint of pantheism in "A Slumber did My Spirit Seal"?', 'Are the ghosts in "The

Turn of the Screw" real or imaginary?', 'Is Lear senile or sane?' and 'Is the woman in *American Gothic* the farmer's wife or daughter?' On Beardsley's view, in simple and complicated cases alike, there are three possibilities: a correct interpretation that takes account of everything in an unambiguous work, a misinterpretation that does not take account of everything in a work, or no interpretation at all. There may be different reasons why an interpretation cannot be given—for example, a poem may exhibit no clear evidence for or against, say, pantheism, a play may exhibit some evidence, say, for a character's sanity and some for his senility and be inconclusive, and so on. For Beardsley, an artwork may be misinterpreted because something in the work is missed or misunderstood or because someone reads something into the work that is not there.

Joseph Margolis

Margolis and others hold a view of interpretation that seems opposed to Beardsley's. Margolis claims that incompatible interpretations of an artwork can be jointly confirmed as plausible, that is, that a person can justifiably accept incompatible interpretations of an artwork as jointly plausible.

Notice that Margolis's account, unlike Beardsley's, is cast in terms of plausibility. Even so, there seem to be problems. Could it ever be jointly confirmed as plausible that Lear is senile *and* plausible that he is sane? The closest that one could come to this would be if the evidence in the play for Lear's senility and his sanity were equal. We would then say that it is just as plausible that Lear is senile as it is that he is sane, but this is very different from saying that it is plausible that Lear is senile *and* sane.

As it turns out, Beardsley and Margolis are not talking about the same thing. Beardsley is talking about the interpretation of the meaning of words, sentences, representations, motives of characters, and the like in artworks. He is concerned, for example, with the questions of whether word order in a poem hints at a pantheistic or mechanistic universe and whether Lear's words and actions are evidence of senility. Margolis is not talking about the discovery *in* artworks of subtle or difficult meanings, he is talking about what Beardsley calls the 'superimposition' of grand schemes such as Marxism and Freudianism onto artworks. Beardsley agrees that artworks—his example is 'Jack and the Beanstalk'—can be read in the light of, or taken as illustrating elements of, Marxism, Freudianism, and the like. Such viewings, however, do not reveal meaning *in* artworks, although they may impose meanings on them. Incompatible superimpositions of an artwork may perhaps be jointly acceptable as plausible, if they can be fitted onto the artwork.

Deconstruction

If Margolis's view is not inconsistent with Beardsley's, the position of the deconstructionists is. This theory did not orginate in the English-speaking world but its influence has certainly reached it. The deconstructionists maintain that because of the nature of signs and language, correct interpretations of artworks are not possible. The deconstructionists conclude that since correct interpretations of artworks (and even of ordinary communications) are not possible, one is free to put any interpretation on artworks that one wishes; indeed one's only option is to understand in this 'free' way.

It is true that even simple communications sometimes fail. But simple communications are not *always* not possible or language would not exist. Language use would never have evolved if communication always were not possible. Cities, airplanes and anything more advanced than a mud hut would not have come into existence if communication were not possible. The fact is that we know how to communicate; we know how to remove ambiguities and obscurities by asking questions and offering clarifications and the like.

Artworks are of course not simple communications. We misinterpret or fail to interpret artworks with some frequency because they are complicated and because some artworks are ambiguous or intractably obscure. Artworks, however, like simple communications, would not exist if the understanding or interpretation of them were not generally possible. The fact is that we know how to interpret artworks and correctly do so with considerable frequency.

If the deconstructionists are right, it is hard to see how they could have been so successful in communicating their view among themselves and to others. The philosophical conclusion that correct understanding or interpretation is not possible is a curious and paradoxical affirmation.

Evaluation

J.O.Urmson

It is most promising to evaluate art instrumentally, i.e. according to its capacity to produce valuable or valued experience. Urmson's 'On Grading' (1950 [13.64]), although not focused on art, is an early account of instrumental evaluation. Urmson's example of grading Red Delicious apples is instructive. There are agreed-on criteria: dark-redness, lack of wormholes, firmness, sweetness, etc. The best apples are dark-red, unblemished, firm and quite sweet, and the remainder sort out below the best. Dark-redness is an aesthetic criterion, firmness and sweetness are taste criteria, and lack of wormholes is indicative of taste quality and is aesthetic as well. All the criteria involve capacity to produce valued experiences—aesthetic or taste.

Applying instrumentalist grading to artworks involves several questions. Are there agreed-on criteria so that relativism can be avoided? How many criteria are there? Are there evaluational principles, and if so, how are they formulated?

Monroe Beardsley

Beardsley believes that *the* function of artworks is to produce aesthetic experience. Since aesthetic experience is valuable, his instrumentalist conclusion is that artworks are to be evaluated according to their capacity to produce this valuable kind of experience.

Beardsley believes that aesthetic experience is detached from the remainder of experience. He, therefore, concludes that the referential aspects of art (those aspects that relate art to the world outside aesthetic experience) are irrelevant to the evaluation of art as art. On his view, only art's aesthetic characteristics are relevant to its value.

As noted earlier, Beardsley thinks all aesthetic qualities are subsumable under unity, intensity and complexity, and he sees these three as the criteria of artistic value. There are, according to him, three corresponding evaluative principles: each principle has one of the three criteria as its subject: for example, 'Unity in an artwork is always valuable (for producing aesthetic experience).' Beardsley's three principles plus complete information about an artwork's unity, intensity and complexity can never logically entail specifie, narrowly focused evaluations such as 'This artwork is *good*' or 'This artwork is *excellent*.' In fact, his three principles can entail only unspecific evaluations such as 'This artwork is *valuable to some degree*.'

Beardsley failed to see that on his theory there are principles that have aesthetic experience as their subjects that *would* logically entail specific, narrowly focused evaluations. An example of such a principle is 'Aesthetic experiences of a fairly great magnitude are always good.' This principle, together with the information that an artwork can produce an aesthetic experience of fairly great magnitude, entails that the

artwork can produce a *good* aesthetic experience. If an artwork can produce a *good* aesthetic experience, then the artwork itself is *instrumentally* good.

Beardsley avoids relativism because, on his theory, there can be no disagreement over whether an artwork's characteristics produce one kind of value experience in one person and a different kind in another person. For Beardsley, an artwork can produce instrumentally valuable aesthetic experience which in turn is instrumentally valuable for producing mental health, and whether aesthetic experience produces mental health is an empirical matter.

If Beardsley's theory were correct, there would be evaluational criteria and corresponding evaluational principles. The question of *agreeing on* criteria would not arise because unity, intensity and complexity are just properties that produce aesthetic experience. Furthermore, the value of every artwork could be compared with that of every other work because artworks' values are determined by their capacity to produce one kind of thing—aesthetic experience.

Unfortunately, there is good reason to think that Beardsley's conception of aesthetic experience is defective and that the valued experiences that are relevant to the instrumental evaluation of art are more complicated than he envisaged. Relativism is still a possiblity.

Frank Sibley

According to Sibley in 'General Criteria and Reasons in Aesthetics' (1983 [13.63]), Beardsley desires to require that the presence in an artwork of any one of his criteria—unity, intensity, complexity—must always contribute positively to an artwork's overall value. Thus, for Beardsley, a critical principle must have the form: '——in an artwork is always valuable' with 'valuable' being understood to entail 'contributes to overall value'. Sibley argues that Beardsley's desired requirement cannot be maintained because *interactions* among his three criteria are possible; for example a work's complexity may cause a work to be disunified. The presence of a valuable property *a* in a particular degree in a given work may interfere with achievement of a particular degree of another valuable property *b* in that work and cause the work's overall value to be less than it would be if the degree of *a* were of some other magnitude.

Sibley also maintains that there are many aesthetic properties of artworks that are not subsumable under unity, intensity and complexity. He claims there are *positive* aesthetic properties besides unity, intensity and complexity—for example gracefulness, delicacy. He also claims that there are many negative aesthetic properties—garishness, insipidness, and the like.

On Sibley's view, there will be as many critical principles as there are aesthetic properties—positive and negative. Since any one of the aesthetic properties can interact with non-aesthetic or other aesthetic properties in an artwork to reduce (or enhance) overall value, critical principles must be formulated in a way that reflect this fact. Principles of the kind Sibley has in mind would have to have the form: '——in an artwork, in isolation from the other properties of the work, is always valuable.' This says that, for example, gracefulness is a valuable property but that it cannot be fitted in everywhere. The application of such principles to artworks always requires qualifications about interactions among the various properties of artworks. Sibley's principles can entail only unspecific evaluations of artworks such as 'This artwork is valuable to some degree.'

For Sibley, artworks are instrumentally valuable because they can produce valuable experiences, but he does not claim, as Beardsley does, that artworks produce a single kind of instrumentally valuable experience. Thus, on his view, it is possible that persons can derive different value-experiences from an artwork and relativism is not ruled out.

Nelson Goodman

Goodman disagrees with Beardsley (and Sibley) that it is the possession of aesthetic qualities that makes art valuable, claiming that art's value is a function of the symbolizing or reference of its cognitive aspects. He agrees that art is to be evaluated by its capacity to produce aesthetic experience, but he claims that aesthetic experience is cognitive in nature and not a matter of aesthetic qualities.

The cognitive aspects of art are frequently valuable. The crucial cases for Goodman, however, are non-objective paintings and instrumental music. He claims such works are valuable because their dominant characteristics symbolize themselves (by *exemplification*), that is, that the characteristics are valuable because they are *samples* of themselves, like paint chips at a paint store.

Consider a non-objective painting entitled *#3* that is uniformly painted a brilliant red. Does it function like a paint chip? One could use it as an example of the colour one desires for a car, but this is not the typical way we use such paintings. Non-objective paintings as they are typically experienced do not exemplify. (So, all artworks do not symbolize.) Paint chips *are* valuable because they are samples, but the colours they exemplify are or can be non-referentially valuable. Valuable non-objective paintings are typically valuable in a similar non-referential way.

Similarily, the brilliant red of a sunset is a paradigm of aesthetic value and of course it does not typically exemplify anything. Assume *#3* to be the same shade of red as this sunset; typically such a painting will be valuable in the way that the sunset's colour is even if it were valuable because it is a sample.

Goodman is right that the cognitive content of art can have artistic value, but Beardsley is right that the possession of aesthetic qualities can have artistic value. Both neglect a valuable aspect of art.

Bruce Vermazen

Beardsley and Goodman attempt to evaluate artworks on the basis of *one* complex property, namely an artwork's capacity to produce a particular kind of valuable experience. This would make the values of artworks the function of a single property and make every artwork's value comparable to that of every other. Unfortunately, their conclusions are not proven.

Vermazen in 'Comparing Evaluations of Works of Art' (1975 [13.65]) claims persuasively that artworks' values are a function of multiple independently valuable properties. If two artworks have different independently valuable properties, it will be impossible to compare their value—it is an apples-and-oranges situation. If two artworks each have the same independently valuable property and only that one valuable property, then their values can be compared and ranked. Vermazen then shows that if two artworks have the same independently valuable properties but have two or more such properties, it will be possible to compare and rank the values of the two artworks if the values of the properties are of a certain sort but that it will not be *generally* possible to compare and rank the values of all such pairs of artworks. Vermazen's article shows that the kind of evaluational programme Beardsley and Goodman have in mind will not work.

For a more extensive discussion of the evaluation of art, see my *Evaluating Art* (1988 [13.60]).

CHAPTER 14
Philosophy of religion

Edward R.Wierenga

Philosophy of religion is critical reflection on philosophical issues that arise in religion. Sources of such issues include religious *claims* (for example, that God exists, about which it can be asked what it means, whether it is true or whether it is reasonable to accept), *concepts* (for example, omniscience or immutability, about which it may be asked how they are to be analysed or whether they are compatible with each other) and *practices* (for example, prayer, about which it may be asked whether it is sensible to express a thought or desire that God already knows one to have). Although all religions suggest topics for philosophical scrutiny, philosophers writing in English in the twentieth century have focused their attention primarily on philosophical issues raised by theism, no doubt because Christianity was the religion with which the majority were most familiar. Theism may be defined, as it was by Robert Flint in his book of that name [14.3], as 'the doctrine that the universe owes its existence, and continuation in existence, to the reason and will of a self-existent Being, who is infinitely powerful, wise, and good'. Philosophy that considers the existence and attributes of such an infinitely powerful, wise and good being, that is, God, is often called philosophical theology. Other topics that philosophers of religion have addressed include mysticism and the nature of religious experience, the relation between religion and science, religious language, the nature of religion and immortality. In addition, in the final decades of the century some philosophers of religion have begun again to work on more specifically theological topics, such as the Christian doctrines of the incarnation, atonement and original sin.

There is perhaps no other specialty of philosophy that is so closely intertwined with work in other areas of philosophy. Philosophy of religion reflects, reacts to, and borrows from the rest of philosophy. In the early years of the century, when idealism and metaphysical system-building were fashionable, philosophers of religion attempted to incorporate such religious claims as were amenable into a comprehensive metaphysical framework. In the middle years of the century philosophers of religion attempted to respond to the logical-positivist attack on metaphysics and religion. Philosophers party to these disputes debated not about whether religious claims are true or justified but about whether they are so much as meaningful. In the final third of the century philosophy of religion has become more technical and specialized, borrowing insights from work in philosophical logic, for example, and applying them to some of the traditional arguments for and against God's existence.

IDEALISM

Many of the most distinguished philosophers of religion have been invited to give the Gifford lectures, a series of lectures held each year at one of the Scottish universities (Aberdeen, Edinburgh or Glasgow) to promote 'the study of Natural Theology in the widest sense of the term—in other words, the knowledge of God'. In

1900 those lectures were given for the first time by an American, Josiah Royce, of Harvard University. Royce was the foremost American exponent of absolute idealism, a speculative philosophical view according to which there is one spiritual, self-conscious being—the Absolute—and everything that is real is so by virtue of its participation in the Absolute. Royce himself seems to have come to this view through the influence of the German idealists, in particular, Hermann Lotze. However, absolute idealism was also the dominant doctrine in British philosophy at the beginning of the century, represented by such defenders as Edward and John Caird, as well as by T.H.Green.

Royce's Gifford lectures, published as *The World and the Individual* [14.7], employed an argument that Royce developed in several places, namely, that the possibility of error can be used to show the existence of the Absolute. Royce held that the 'external meaning' of an idea depends upon what it is intended to mean. Furthermore, that an idea fails to correspond to what is intended—that an idea is in error —therefore depends on there being an intelligence that grasps both the idea and its intended object. Finally, since there are infinitely many possibilities for error, there must be an infinite intelligence—the Absolute—that understands them all.

Andrew Seth Pringle-Pattison, in his Gifford lectures of 1912–13, *The Idea of God in the Light of Recent Philosophy* [14.4], agreed with Royce's idealism, holding that 'self-conscious life [is] organic to the world', but he denied that all consciousness is unified into a single self. God is thus not to be identified with the Absolute. This personal idealism was also defended by Hastings Rashdall in his *Philosophy and Religion* [14.5].

WILLIAM JAMES AND PRAGMATISM

An alternative to the speculative metaphysics and grand system-building of the absolute idealists (and of the later Whiteheadians) was the problem-driven, piecemeal approach to philosophy practised by William James and other pragmatists. In 'The Will to believe' [14.9] James took up the challenge of W K.Clifford [14.58] that 'it is wrong always, everywhere, and for every one, to believe anything upon insufficient evidence'. Conceding that there was insufficient evidence in favour of religious belief, James attempted to provide a justification of faith. He distinguished between the intellectual duty to believe truths and the duty to avoid falsehoods, noting that emphasizing the latter obligation would encourage one to withhold assent to a proposition when the evidence for it was not compelling. James urged allegiance instead to the more venturesome obligation to acquire true beliefs. He thought that this provided a justification for choosing to believe a proposition in cases in which one was forced to make a choice, in which the choice made a difference to one's life, and in which the choice could not be decided on intellectual grounds. James held, in particular, that accepting the religious hypothesis, believing that God exists, is permitted by this principle.

In 1901 and 1902 James delivered his *The Varieties of Religious Experience* [14.10] as the Gifford lectures. James defined religion as 'the feelings, acts and experiences of individual men in their solitude, so far as they apprehend themselves to stand in relation to whatever they may consider the divine'. James went on to discuss repentance, conversion and saintliness, but, given the primacy he attached to experience, it is natural that he focused on mysticism. Drawing on the writing of mystics, James characterized mystical experience as ineffable, that is, it defies expression, as having noetic quality, that is, as seeming to its subjects as states of insight into truth, and as transient and passive. James concluded that such states were authoritative for those who had them but they had no evidential value for those who do not have them beyond pointing to the 'possibility of other orders of truth'.

James inaugurated a tradition of investigating the phenomenology and evidential value of mystical experience which continued throughout the century, with the work of W.T.Stace and Nelson Pike being especially noteworthy.

ALFRED NORTH WHITEHEAD AND PROCESS PHILOSOPHY

In 1927–8 the Gifford lectures were delivered by Alfred North Whitehead. Whitehead had begun his career as a mathematician, co-authoring in 1910–13 with Bertrand Russell the monumental *Principia Mathematica*. By the 19203 Whitehead had moved to America and was attempting to develop a speculative metaphysical system inspired by scientific cosmology. The notoriously obscure language of his Gifford lectures, published as *Process and Reality* [14.15], makes them difficult to interpret. Whitehead elaborated a 'dipolar' concept of God. In his 'primordial nature', God is part of the process of the natural world— not the creator and devoid of consciousness—who nevertheless contributes to the order of the world. By contrast, the 'consequent nature' of God is a consciousness that grows as it incorporates the values that arise as things continually change. Whitehead summarized these apparently conflicting strains with a series of aphorisms such as, 'It is as true to say that God creates the World, as that the World creates God.'

Whitehead's rejection of the classical conception of God as immutable, eternal, absolute, omnipotent, and so forth, was found congenial by others who developed his views. Charles Hartshorne, for example, defended a dipolar view of God, and such 'process theologians' as John Cobb attempted to give an explicitly Christian development of Whitehead's thought.

THEOLOGICAL LANGUAGE: VERIFIABILITY AND MEANING

Interest in developing speculative metaphysical systems declined under the influence of logical positivism. This was a school of philosophy developed by Morris Schlick, Rudolf Carnap and other members of the Vienna Circle. It was introduced to English-speaking philosophers by A.J.Ayer in his *Language, Truth, and Logic* [14.16]. The centrepiece of logical positivism was the verifiability criterion of meaning. According to this view a sentence is meaningful only if it is either analytic or empirically verifiable. A satisfactory statement of what was required for a sentence to be verifiable was never found; roughly, however, the idea was that a sentence is verifiable just in case it could at least in principle be established or falsified by empirical observation. Ayer wielded the principle of verification to yield the conclusion that the sentences of traditional metaphysics, of ethics, and of religion are all meaningless. He held that such claims were not analytically true and that there was no conceivable observation that would confirm or refute them. Accordingly, Ayer concluded that these sentences were neither true nor false but meaningless, in particular, 'no sentence which purports to describe the nature of a transcendent god can possess any literal significance'.

Ayer's case was bolstered by a famous example published in the mid-1940s, around the same time that *Language, Truth, and Logic* came out in a second edition. In his essay, 'Gods' [14.20], John Wisdom described an example of two people who observe an apparently untended garden. One thinks that there is a gardener; the other does not. All attempts to detect the gardener fail, yet the one person continues to believe that there exists an unseen and unheard gardener who is manifested only in his works. Although Wisdom held merely that the difference between the two observers 'has ceased to be experimental', other philosophers drew the conclusion that, since no observation would falsify the believer's claim, that claim, that there is an unseen and unheard gardener, is meaningless. Antony Flew, for example, claimed that 'if there is nothing which a putative assertion denies then there is nothing which it asserts either: and so it is not really an assertion' [14.18]. Flew then suggested, with respect to a version of Wisdom's story he elaborated, that

'when the Sceptic in the parable asked the Believer, "Just how does what you call an invisible, intangible, eternally elusive gardener differ from an imaginary gardener or even from no gardener at all?" he was suggesting that the Believer's earlier statement had been so eroded by qualification that it was no longer an assertion at all.' Flew held that theological utterances generally, since they cannot be falsified, are similarly vacuous.

This idea, that the central challenge to religious belief was not that such beliefs are false but that they are not even meaningful, continued to dominate the philosophy of religion into the 1950s. It was shared by most of the contributors to what was the leading collection of essays in philosophy of religion of the decade, *New Essays in Philosophical Theology,* a volume that included, in addition to Flew's piece, essays by R.M.Hare, Basil Mitchell, P.H.Nowell-Smith, and others.

The verificationist challenge to the meaningfulness of religious belief was so widely accepted that even many theistic philosophers and theologians felt compelled to offer reinterpretations of traditional religious assertions that would permit them to pass the verifiability test of meaningfulness. A typical and well-known example of such a response is R.B.Braithwaite's *An Empiricist's View of the Nature of Religious Belief* [14.17]. According to Braithwaite, the Christian's apparent claim that God is love is not a claim about a supernatural reality, but is rather merely an expression of the believer's intention to follow an agapeistic way of life. Other religious utterances are to be understood similarly as expressions of emotion or as declarations of an intention to act in a certain way.

As long as the very meaningfulness of religious utterances was in question relatively little attention was given to other issues in the philosophy of religion. Eventually, however, commitment to the verifiability criterion of meaning waned. This was due primarily to the problems, first, of saying why the criterion should not be applied to itself—for it seemed to be unverifiable—and, second, to the problem of formulating the principle in a way that ruled out sentences of metaphysics and religion without also ruling out clearly meaningful sentences such as sentences of science. The history of this latter problem is detailed by Carl Hempel in 'Problems and Changes in the Empiricist Criterion of Meaning' [14.19].

WITTGENSTEINIAN FIDEISM

A similar preoccupation with religious language was channelled in a somewhat different direction by Ludwig Wittgenstein and his followers. Wittgenstein's most explicit discussion of religion is to be found in his *Lectures and Conversations* [14.25], student notes of lectures he gave in 1938. There he held that the religious believer's use of language is so different from that of the non-believer that the non-believer is unable to contradict the believer. Wittgenstein does not draw the conclusion, however, that the believer's assertions are meaningless. Rather, what the believer means is determined by a 'picture' or way of looking at life that the non-believer does not share.

Employing locutions that Wittgenstein used elsewhere, we can put this view as the claim that the meaning of religious terms depends upon their role in a 'language-game' or in a 'form of life'. Thus, terms such as 'God' or 'judgement day' have a meaning for a believer that depends upon their use in a range of practices in which the believer participates. It does not make sense, then, to attempt to find evidence or justification for religious assertions, for that inquiry is outside the religious form of life in which such assertions have a meaning. Followers of Wittgenstein such as Norman Malcolm and D.Z.Phillips emphasized versions of fideism according to which it is misguided to seek rational grounds for religious belief. On their view, religious belief is groundless; within religious practice it is not a hypothesis for which evidence may be sought, but there is no external perspective from which the religious form of life may be evaluated. Critics, such as Kai Nielsen, have objected that a single conceptual structure may include both

science and religion, in which case the demand for evidence is in order, and, in any event, whole forms of life (e.g. witchcraft) are open to appraisal.

THE PROBLEM OF EVIL

An exception to the prevailing philosophical climate in the 1950s, according to which religious claims were either meaningless or logically isolated to the language-game in which they were used, came in the form of an attack on the truth of theism. In 1955 J.L.Mackie inaugurated a period of intense interest in the problem of evil by presenting a forceful challenge to theism. H.D.Aiken, Antony Flew and H.J. McCloskey also published versions of this objection. According to Mackie, theism is not merely false, but inconsistent, because its central tenets could not possibly all be true. Theists hold that (1) *God is omnipotent,* (2) *God is wholly good* and (3) *There is evil.* According to Mackie, these propositions are contradictory in the sense that if any two are true, the remaining one would have to be false. This is what has since become known as the *logical problem of evil*. Mackie noted that in order to demonstrate that the theistic beliefs are contradictory one would have to find some necessarily true propositions—he called them 'quasi-logical rules'—connecting the concepts of omnipotence, goodness and evil in such a way that in conjunction with the theistic beliefs an explicit contradiction is deducible. Mackie's candidates for the requisite necessary truths were (4) *There are no limits to what an omnipotent being can do* and (5) *A good being eliminates evil as far as it can.* Critics such as Nelson Pike and Alvin Plantinga pointed out that, since a good person could permit evil if the person had a good reason, (5) is not a necessary truth. Subsequent attempts to substantiate Mackie's charge failed to uncover variants of (4) and (5) with the twin features of being necessarily true and of entailing, in conjunction with the theistic beliefs, an explicit contradiction. That leaves it open, however, that the theistic beliefs are inconsistent, even if it has not been shown that they are. Accordingly, a sizeable body of literature has been produced in the attempt to show that theism is consistent.

Plantinga defined a *defence* against evil as the attempt to show that the existence of God and the existence of evil are logically consistent with each other. By contrast, a *theodicy* is the attempt to say what the real reason or correct explanation for evil is. A defence, therefore, can succeed if it provides a logically possible scenario in which God and evil co-exist. The free-will defence was supported in a short reply to Mackie by S.A.Grave and developed with great ingenuity by Alvin Plantinga. Its main idea is that it is possible that God valued having free creatures but was unable, despite his omnipotence, to create such creatures who only do what is right; since, if God causes someone to do what is right, that person does not do it freely. If this scenario is possibly true, then it is possible both that God exists and that there is evil.

The free-will defence explicitly addresses so-called moral evil, that is, evil that results from the free actions of created agents. Critics have noted that there is also the question of the compatibility of God's existence with natural or physical evil, such as suffering due to earthquakes or floods. Plantinga's response is that it is possible that all evil is moral evil, since it is possible that apparently physical evil is caused by non-human agents. Despite this being only a claim of possibility, it has been controversial. Other philosophers, for example Richard Swinburne and Peter van Inwagen, have suggested that natural evil is due to the regular operation of physical laws and that the value of having physical laws outweighs the resulting evil.

An alternative to the free-will defence, promoted by John Hick, emphasizes the value of evil for the growth of people's characters. According to Hick, evil provides an opportunity for 'soul-making' or spiritual development, which is required for people to become fit for a relationship with God; evil is thus not simply an unfortunate consequence of having creatures with free will. Hick derived this view from Irenaeus (120–202), and Hick regarded it a virtue of this account that it avoids the Augustinian doctrine of the Fall and the

consequent problem of explaining how the good creation of a perfect God could become evil. Hick clearly intended his account to be a theodicy, but, if it is possibly right, it also provides a defence against the logical problem of evil.

Thus far the discussion focused on the logical problem of evil, but as philosophers became convinced that an adequate defence could be made against it, a second problem, *the evidential problem of evil,* began to attract attention. According to William Rowe, among others, the existence of evil, while not logically incompatible with the existence of God, is nevertheless evidence against God's existence; given the evil that there is in the world, the reasonable conclusion is that God does not exist. One response, defended by William Alston, is to hold that we are not in a position to know whether evil that appears to be gratuitous or unjustified really is; if there were a God he would likely have reasons for permitting evil that human beings could not even grasp. A second response, developed by Plantinga, concedes that *God exists* is improbable given *There is evil* but holds that *God exists* need not be improbable on a theist's total body of evidence. The issues here have to do with religious epistemology, to be discussed below.

THE ONTOLOGICAL ARGUMENT

A period of intense activity in philosophy of religion was inaugurated in 1960 when the *Philosophical Review* published an article by Norman Malcolm [14.41] in which Malcolm claimed to have found a sound version of Anselm's ontological argument for God's existence. Anselm (1033–1109) had held that God, understood as the being than which nothing greater can be conceived, must exist; for the assumption that God does not exist leads to the absurdity that it is conceivable that there is something which is greater than the being than which nothing greater can be conceived. Malcolm was willing to concede, as most philosophers at the time thought, that this version of the argument was refuted somehow by Immanuel Kant's (1724–1804) claim that 'existence is not a predicate'. Malcolm held, however, that there was a second argument in Anselm's *Proslogion,* one according to which *the logical impossibility of non-existence* is a perfection. Thus, if God is a being than which a greater cannot be conceived, he must exist necessarily, if at all. So either God's existence is necessary or it is impossible. According to Malcolm, God's existence is impossible only if the concept of God is self-contradictory or nonsensical. Malcolm denied that the concept of God is in this way impossible; accordingly, God exists necessarily.

Charles Hartshorne had presented a similar argument twenty years earlier, but his work had not attracted the same attention. By contrast, more than a hundred articles were submitted to the *Philosophical Review* in response to Malcolm's piece, of which the journal published a handful before enforcing a moratorium on the topic. Work on the argument continued, nevertheless. David Lewis applied insights derived from possible-world semantics for modal logic—an interpretation of claims about necessity and possibility in terms of logically possible worlds—to a version of Anselm's argument, a version that Lewis claimed to be defective. Alvin Plantinga proposed another modal version, which, though he claimed it to be sound, he conceded did not succeed as a proof. Nevertheless, Plantinga insisted that such an argument could demonstrate the rationality of belief in God, since someone could rationally believe its premise and rationally recognize that the conclusion that God exists follows from it.

ANALYTIC PHILOSOPHY OF RELIGION

Just as discussion of the ontological argument ushered in a period of renewed interest in the philosophy of religion, it also marked the introduction of greater rigour and more technical methods into the field. Signs of interest in the field included the founding of several journals devoted to the philosophy of religion. *Sophia,*

committed to discussion of philosophical theology, was inaugurated by the University of Melbourne in 1962; *Religious Studies,* published by Cambridge University Press, began in 1965; and the *International Journal for Philosophy of Religion,* edited in the United States and published in the Netherlands, commenced in 1970. Increased rigour resulted in part from a more careful attention to arguments. It was due, in addition, to the fact that philosophers of religion appealed to insights from other areas of philosophy, which were also becoming more technical. Thus, as noted above, work on the ontological argument drew on work in modal logic. Other areas of philosophical logic, for example, theories of counter-factual conditionals, came to figure in treatments of the problem of evil; metaphysical doctrines about the fixity of the past were applied to the topic of foreknowledge and free will; and probability theory was applied to arguments for and against God's existence.

The most influential work in analytic philosophy of religion in the 1960s was Alvin Plantinga's *God and Other Minds* [14.48]. In it Plantinga applied the techniques of analytic philosophy to the traditional arguments for God's existence as well as to arguments against God's existence, notably the problem of evil. Plantinga claimed that these arguments are all unsuccessful. However, he then examined the analogical argument for the existence of other minds—an argument for the conclusion that other people have mental states that appeals to the premise that their behaviour is analogous to one's own behaviour when one is in certain mental states. Plantinga held that this argument, though unsuccessful, is the best argument we have for the existence of other minds. He claimed, furthermore, that its defect is the same as the defect he had uncovered in the argument from design for God's existence. He concluded that since it is nevertheless rational to believe in other minds, it is also rational to believe in God.

Another topic to attract attention was that of the attributes of God. In his Wilde Lectures in 1970–2, later revised as *The God of the Philosophers* [14.44], Anthony Kenny took up such topics as divine omniscience, omnipotence, and immutability. Drawing on the work of Arthur Prior and Norman Kretzmann, he argued that if God is omniscient then he is not immutable. He further claimed if God has infallible knowledge then determinism is true and God is responsible for human wickedness. Kenny concluded that 'there cannot…be a timeless, immutable, omniscient, omnipotent, all-good being'. By contrast, Richard Swinburne in *The Coherence of Theism* [14.52], the first volume of his important trilogy in philosophical theology, attempted to describe 'what it means to claim that there exists eternally an omni-present spirit, free, creator of the universe, omnipotent, omniscient, perfectly good, and a source of moral obligation', and he endeavoured to show that this central claim of theism is 'coherent'. Swinburne's presentation involved attenuating certain of the attributes somewhat. For example, on the assumption that God is contingent, omniscience requires, not knowledge of all truths, but, at any given time, knowledge of every true proposition about that time or an earlier one and knowledge of only those propositions about future times that report events that are physically necessitated at the earlier time. And for Swinburne divine eternity meant being everlasting, rather than the more traditional, Boethian, idea of a simultaneous, timeless grasp of an illimitable life. On the other hand, if God is a necessary being, then, according to Swinburne, the theist needs to use some predicates of God *analogically* rather than literally.

In the decade following the publication of these seminal works, Edward Wierenga attempted in *The Nature of God* [14.54] to provide philosophically defensible accounts of several of the divine attributes, accounts that he claimed were adequate to the demands of classical theism as well as immune to the kinds of objections raised by Kenny. The question of whether divine foreknowledge is compatible with human free action attracted considerable attention. Many philosophers felt compelled to point out, as Aquinas had done much earlier, that a certain simple argument for incompatibility is fallacious. That argument is: (1) If God knows in advance that a person will perform a certain action, then the person must perform it. (2) If a person must perform a certain action, then the person does not do so freely. Therefore, (3) if God knows in

advance that a person will perform a certain action, then the person does not do so freely. The first premise is ambiguous. It can be taken as the truth (1) Necessarily, if God knows that a person will perform a certain action, then the person will do so; but so taken the conclusion does not follow. The conclusion does follow if the premise is understood as (1) If God knows that a person will perform a certain action, then the proposition that the person will perform that action is necessarily true; but under this interpretation the premise is false.

A considerably more vexing argument for the incompatibility of divine foreknowledge and human free action appeals to the apparent fixity or necessity of the past. According to this argument, what God in the past believed about the future is now part of the past and thus fixed or unalterable. Also, what follows of necessity from what is thus fixed is itself fixed or unalterable. But it follows of necessity, given God's (essential) omniscience, that if he knew in the past that someone would perform a certain action tomorrow that that person will perform the action. So the proposition that the person will perform that action is fixed or unalterable. Then, however, it is not up to the person whether he or she performs the action; so the action is not free. A version of this argument was presented by Nelson Pike in *God and Timelessness* [14.47]. In *God, Time, and Knowledge* [14.43] William Hasker argued that the standard defences of the compatibility of divine foreknowledge fail. In particular he objected to the Ockhamist response, which holds that propositions about God's past foreknowledge are not strictly about the past, and he objected to the eternalist response, according to which God is outside time. Hasker claimed that solutions to the problem require that we have a power over the past that in fact no one has. Linda Zagzebski also took up this topic in *The Dilemma of Freedom and Foreknowledge* [14.55]. Although sharing Hasker's scepticism with respect to the traditional responses, she argued that two assumptions of the above argument, namely that fixity is transferred by entailment and that actions fixed in the relevant sense are not free, may both be rejected.

In addition to the ontological argument, discussed above, analytic philosophers of religion have discussed other arguments for God's existence. In *The Cosmological Argument* [14.50], William Rowe examined versions of the argument that derives from the assumption that contingent things exist now the conclusion that there was a first cause, namely God, of what exists. Rowe claimed that this argument failed as a proof of theism but concluded that it may show the reasonableness of theistic belief. Richard Swinburne considered a variety of theistic arguments in *The Existence of God* [14.53]. Swinburne emphasized the explanatory power of the theistic hypothesis and claimed that the cumulative case of several arguments taken together renders the proposition that God exists more probable than not. In this conclusion, if not in the detailed way he arrived at it, Swinburne's position resembled that of Basil Mitchell, his predecessor as Nolloth Professor of Philosophy of the Christian Religion at Oxford University.

RELIGIOUS EPISTEMOLOGY

Just as at the beginning of the century William James had responded to W.K.Clifford's dictum that it is always wrong to believe a proposition on insufficient evidence, so in the final third of the century was interest in religious epistemology rekindled by the evidentialist challenge to the rationality of theistic belief. As Antony Flew put it,

> If it is to be established that there is a God, then we have to have good grounds for believing that this is indeed so. Until or unless some such grounds are produced we have literally no reason at all for believing; and in that situation the only reasonable posture must be that of either the negative atheist or the agnostic.
>
> ([14.59], p. 22)

This objection may be put as an argument: (1) It is rational to believe that God exists only if there is sufficient evidence for God's existence. (2) There is not sufficient evidence for God's existence. Therefore, (3) it is not rational to believe that God exists.

Alvin Plantinga suggested that this demand for sufficient evidence appeals to classical foundationalism. According to the latter doctrine, some propositions may be rationally believed without being based on other beliefs. Such 'properly basic propositions', according to Plantinga's construal of classical foundationalism, either are self-evidently true, are ones that a person could not possibly believe without their being true, or are evident to the senses. Any other proposition may be rationally believed only if it is justified by, supported by or evident with respect to properly basic propositions. The evidentialist objection may then be reformulated as: (1) It is rational to believe that God exists only if the proposition that God exists is properly basic or evident with respect to propositions that are properly basic, (2 a) The proposition that God exists is not properly basic, (2 b) The proposition that God exists is not evident with respect to propositions that are properly basic. Therefore, (3) it is not rational to believe that God exists. Plantinga claimed, first, that it is at least dubious that the proposition that God exists is not properly basic—perhaps classical foundationalism's standards for what counts as properly basic are mistaken. Second, however, if those criteria for what it takes to be properly basic are correct, then it is not rational to believe the first premise of the argument; for (1), itself, is neither properly basic nor evident with respect to propositions that are. The argument is therefore defective: if the second premise is false, the argument is unsound, but if the second premise is true, then it is not rational to accept its first premise.

Not content with merely rebutting the evidentialist objection to theistic belief, philosophers turned their attention to providing epistemological theories according to which theism was justified. Plantinga himself defended a view according to which a person's belief in a proposition is justified just in case the belief is produced by that person's epistemic faculties functioning properly (in circumstances for which they were designed). Plantinga's preferred account of a person's faculties functioning properly is that they function in the way God intended them to function. A theist, furthermore, might think that God would design people in such a way that they came to hold a belief in his existence; if so, such a belief would be justified.

William Alston claimed that beliefs should be evaluated by reference to the epistemic practice within which they arise. He then noted the difficulty of justifying, in the sense of providing good evidence in favour of, the perceptual epistemic practice in which our ordinary beliefs about the world arise. Alston suggested that our perceptual practice is justified only in a weaker sense according to which there are no good objections to it or it is not irrational to participate in it. Finally, Alston argued that what he called Christian mystical practice, which yields beliefs about God in the presence of religious experience, is in striking respects analogous to perceptual practice. In particular, it is 'rationally engaged in since it is a socially established doxastic practice that is not demonstrably unreliable or otherwise disqualified for rational acceptance'.

THEOLOGICAL TOPICS

At the close of the twentieth century, two trends appeared to emerge in the philosophy of religion. One was an expansion of the field to include or at least border on any philosophical work that takes an explicitly theistic perspective. For example, the divine-command theory of ethics, a meta-ethical theory which holds that God's commands determine the moral status of actions, came to be treated in the textbook anthologies of philosophy of religion. In addition, philosophers of religion took notice of such work as that of the authors collected in *Christian Theism and the Problems of Philosophy* [14.62], philosophers who appealed to tenets of theism in their work in metaphysics and epistemology.

A second trend was for philosophers of religion to direct their attention, often sympathetically, to explicitly theological topics, especially to the doctrines of Christian theism. For example, in *The Logic of God Incarnate* Thomas Morris used the tools of analytic philosophy to defend the doctrine of the incarnation, the belief that Jesus was both fully God and fully human. Morris was particularly concerned to rebut such critics as John Hick, who objected that this doctrine was incoherent by claiming that the properties essential to divinity and the properties essential to humanity are incompatible with each other. Other topics to attract attention were the Christian doctrines of the Trinity—that God is three persons in one —and of the atonement —that Christ's sacrifice restores sinful people to a right relationship with God. Philip Quinn wrote a series of papers detailing and criticizing the theories of the atonement proposed by Aquinas, Abelard and Kant. Richard Swinburne took up the topic in the first volume of a series on theological issues; the second volume, on revelation, addressed another issue of theological interest.

Glossary

absolute idealism —a school of philosophy in both Britain and the United States in the late nineteenth and early twentieth centuries. Influenced by Hegel, F.H.Bradley was its main exponent. It stressed the unreality of space, time and physical objects and held that reality was indivisible and spiritual. There is one spiritual, self-conscious being—the Absolute—and everything that is real is so by virtue of participation in the Absolute.

accident —a property that does not apply to an object necessarily, to be contrasted with essential properties.

actual world —the possible world at which all actual truths obtain.

actuality —the feature that distinguishes our possible world from the others and real things from those which are merely possible.

analytic —see analytic truth.

analytic truth —a statement that is true just in virtue of the meanings of its constituent terms. Contrasts with 'synthetic truth'.

anti-realism —a metaphysical position which denies realism, the view that there is a mind-independent world with which assertions must correspond in order to be true.

***a posteriori* knowledge** —knowledge that depends on a specific sensory or perceptual experience.

***a priori* knowledge** —knowledge that does not depend on any specific sensory or perceptual experience.

argument from design —an argument for the existence of God that appeals to the evidence of design in the universe as a reason for thinking that there is a designer.

Äusserungen —a term of art in Wittgenstein for certain first-person psychological utterances such as 'I am afraid.' Their characteristic feature is that they are not *descriptions,* and in particular not descriptions of the inner. *Äusserungen* have the same function as more primitive reactions or expressions which they replace; for example 'I am afraid' may be functionally equivalent to a groan of fear.

being —in Meinong's theory, the widest category of objects, only some of which have the property of existence.

binary function —a function relating two arguments to a value (the way, for example, addition is a function of two numbers having their sum as the value of the function for those arguments). Gottlob Frege interpreted relations between objects as binary functions with truth values, the true or the false, as their values.

brain in a vat —a thought experiment described by Hilary Putnam, according to which we might just be brains kept alive by a mad scientist in a vat of nutrients.

causal theory of names —what a name refers to on some occasion is determined by the causal chain between that use and previous uses of the name to refer to some object.

common law —a system of law originating in England after the Norman conquest consisting of decisions made by courts in cases where there is no controlling legislation. One of its fundamental principles is that courts have an obligation to follow precedent and treat like cases alike and so earlier decisions become a source of law for later ones. Today common law is usually divided into three branches—contract, property, and tort. Although many jurisdictions now have codes of criminal law important aspects of criminal law remain common law. The common law spread to many parts of the British Empire and forms the basis of law in such countries as Australia, Canada and the United States.

common-sense view of the world —a view, espoused by G.E.Moore in his 'Defence of Common Sense' (1925). It rejected any philosophical proposition that conflicted with certain common beliefs of ordinary life.

consequentialism —at their simplest, consequentialist theories of right and wrong locate these moral characteristics of acts in the comparative goodness or badness of their consequences: the better or worse its consequences, the more right or wrong the act. In more complicated forms of consequentialist theory, the connection between actions and morally significant consequences is indirect. Acts are not right or wrong according to the relative merit of their own immediate consequences, but rather, according to the more general consequences of those moral practices or aspects of moral character to which actions of the kind in question might be attached. An act which by itself produces good consequences might thus be a very bad way of acting. Moore's view that for epistemological reasons we ought to abide by the dictates of the rules of common sense is one form of indirect consequentialism.

cosmological argument —an argument for the existence of God that derives from the assumption that contingent beings exist the conclusion that there is a First Cause, namely, God.

counterpart —in David Lewis's modal theory objects do not exist in more than one possible world. Statements attributing an essential property to an object really attribute it to the object and all of its counterparts in other worlds, the objects in those worlds most similar to the original.

criterion —in the later Wittgenstein a criterion is a test, holding in virtue of a rule of language, for the truth of a judgement. So the criterion for being an international grandmaster in chess is that one have such and such a numerical rating gained in such and such a way, as dictated by an explicit rule.

de dicto necessity —necessity of the *dictum* or proposition, a general necessary truth, contrasted with those that attribute a property necessarily to an object. (*See de re* necessity.)

_de re_ necessity —necessity of the thing. (*See de dicto* necessity.)

definite description —a phrase that begins with the word 'the' followed by a noun or noun phrase, for example, 'the present King of France' and 'the oak table with the Limoge vase'.

deontological ethics —deontological theories take right and wrong, rather than good and bad, as the primary notions of morality. Etymologically, 'deontology' comes from the Greek words *deon* (duty) and *logos* (science). Deontological approaches to ethics are non-consequentialist in denying that questions of duty, or of the right, are necessarily parasitic on questions of the good. What one ought to do is not simply a matter of what will produce the best consequences, but primarily a question about what kinds of acts one ought or ought not perform.

domain —in logic, the range of interpretation of the quantifiers, 'there are' and 'for all'. The domain of a possible world is the class of objects which exist at, or according to, that world.

doxastic —belief-oriented. A psychological state is doxastic if and only if it includes belief as an essential component.

Duhem, Pierre —a prominent French physicist and philosopher of science (1861–1916). He is best known among philosophers of science for his version of epistemic holism according to which a scientific hypothesis is always tested on the basis of other hypotheses, so that confirmation and falsification are conditional on accepted hypotheses.

emotivism —a kind of non-cognitivism, emotivism holds that moral claims, such as 'lying is wrong', merely serve to vent a speaker's emotional reaction to his or her subject matter, or perhaps evoke a similar emotional reaction in the speaker's audience. On this view of moral discourse, moral claims do not make statements about anything at all, not even the speaker's own emotional state; instead, they function as actual expressions of a particular emotional response to whatever it is they purport to be about.

empiricism —the evidence of the senses—e.g. visual, auditory, tactile or gustatory experiences—is a sort of evidence appropriate to genuine knowledge. (Strict empiricism: *only* the evidence of the senses is appropriate to genuine knowledge.)

epistemic coherentism —all justification is inferential and systematic in virtue of coherence relations among beliefs.

epistemic contextualism —justification has a two-tier structure in that some beliefs are 'contextually basic'—i.e. taken for granted in a context of inquiry — and all inferentially justified beliefs depend on such contextually basic beliefs.

epistemic foundationalism —justification has a two-tier structure in that some instances of justification are non-inferential, or foundational, and all other instances

of justification are inferential, deriving ultimately from foundational justification.

epistemic holism —*see* epistemic coherentism.

epistemic infinitism —regresses of inferential epistemic justification are endless, or infinite.

epistemology —the theory of knowledge, the philosophical study of the nature, origin and scope of knowledge.

essential property —a property an object has necessarily, that is, in every possible world.

essentiality of origin —the thesis that the origins of an object, what it is originally made from, for example, in the case of an artifact, is an essential property of it.

ethical intuitionism —ethical intuitionism supposes that the human mind includes a cognitive faculty that enables it to apprehend, in a direct sort of way, the presence or absence of moral properties as they actually exist in the objects of moral thought. Although intuitionism is, strictly speaking, an epistemological theory, it is often presented as a form of ethical objectivism.

ethical naturalism —ethical naturalism, a kind of objectivism, holds that moral claims are true or false depending on the way in which the natural world is actually configured. It should not be confused with naturalized ethics, which represents a more contemporary, positivistic effort to account for ethical thought and behaviour on the basis of certain natural aspects of human psychology and social interaction. Unlike the earlier naturalism of Dewey or Perry, which is also based on natural facts related to human psychology and society, naturalized ethics is typically advanced as a form of ethical subjectivism or non-cognitivism. For representative examples of each see Harman [5.26] and Gibbard [5.21].

ethical non-cognitivism —ethical non-cognitivism comprises those metaethical theories which hold that moral claims are not prepositional: moral claims do not express statements which are either true or false, depending on the way the world is. Loosely put, there are no moral properties, subjective or objective, of which the human mind might enjoy any sort of cognitive awareness.

ethical non-naturalism —ethical non-naturalism, a kind of objectivism, holds that moral claims are true or false depending on the way in which certain non-natural aspects of the world are actually configured. Advanced by G.E. Moore in 1903, this view has remained an historical anomaly.

ethical objectivism —objectivists about morality hold that moral claims express propositions, and that what makes these propositions true or false are features of the world that exist independently of human beliefs about morality.

ethical subjectivism —subjectivists about morality also hold that moral claims express propositions, but think that what makes these propositions true or false are the moral responses of the speaker or his or her community to whatever it is that the claims are about. In saying that lying is wrong, for example, I make a statement about my own moral beliefs, or perhaps my community's moral beliefs.

extension —the set of objects of which a predicate is true is its extension. Properties are also said to have as an extension the set of their instances.

fallibilism about justification —there can be false justified beliefs.

family resemblance —Wittgenstein holds that the items belonging to the extension of a given term such as 'game' may fail to share necessary and sufficient features in virtue of which they fall under the term. Rather properties may be distributed among the class of items in a way analogous to the manner in which features are allocated among the various members of a family. A and B may share the family hair colour but not the family nose, B and C the family nose but not the hair colour, and so on.

first-order logic —logic where quantifiers 'all' and 'some' range only over individuals and not higher-order entities such as properties or predicates.

free-will defence —the attempt to show that God's existence is compatible with the existence of evil by appealing to the value of creatures with free will.

functionalism —theory in the philosophy of mind by which mental notions such as pain are to be defined by the causal role or function they perform mediating between sensation and action.

Gettier problem —the problem of finding a modification of, or an alternative to, the standard justified-true-belief analysis of knowledge that avoids difficulties from counter-examples to that analysis inspired by Edmund Gettier in 1963.

grue —Goodman's fabricated predicate, true of those things that are examined before the year 2000 and found to be green, otherwise blue things.

haecceitism —the thesis that one object can occur in different possible worlds, without requiring that they have any distinctive individual essence that grounds that identity.

haecceity —the non-qualitative ground of identity of an object across possible worlds, as a 'thisness' contrasted with a qualitative quiddity, or 'suchness'.

historical theory of names –*see* causal theory of names.

idealism about something , *x*—the existence of *x* depends on the intellectual or perceptual processes of a conceiver.

immanent universals —the view that universals are located (wholly) in each of their instances, and depend on them ontologically. Thus there can be no uninstantiated immanent universals.

indexical —an expression such as 'I', 'now', 'here', 'this' and 'that' which depends for its interpretation on the context of utterance.

individual —entity of basic ontological category. Concrete particulars, spatiotemporally located physical objects are model individuals, although other sorts, including abstract entities, may be included. Defined in logic as objects of the lowest logical type.

individual essence —essential property had by at most one object.

individuation —process by which an entity is distinguished from its environment at one time and through time.

inferential justification —the justification of one belief depends on another belief or set of beliefs.

inherence —variously, relation or non-relational tie between a property or universal and its instances.

intensionality —semantic characterization of an expression in which expressions with the same reference or same extension cannot be substituted for each other. Contrasts with extensionality.

internal relations, doctrine of —a metaphysical principle, espoused by F.H. Bradley, which held that relational properties are reducible to intrinsic properties and, ultimately, unreal.

intrinsic —property internal to an object, independent of its relations with any other object.

lambda-operator —the lower-case Greek letter *lambda* used as a variable-binding operator for generating function-expressions from other expressions. It was used in this way to characterize the notion of an algorithm (recursive function) by Alonzo Church in his *The Calculi of Lambda-Conversion,* and also in his simple type theory to generate complex expressions for functions (including concepts as functions from objects to truth values). Rudolf Carnap, Richard Montague and others followed Church in this use of the lambda-operator.

language-game —a term from Wittgenstein's later philosophy denoting a custom-regulated pattern of interaction in which words play a role. For instance in the language-game of the builders in §2 of the *Philosophical Investigations* the role of the word 'slab' is to indicate the type of building block the helper is to bring in response to the call 'Slab!'

legal positivism —the view that no moral judgement need be involved in determining what the law is. It is usually contrasted with natural law theory (q.v.). It is especially associated with John Austin (1790–1859) who spoke of law as the command of a sovereign to that sovereign's subjects backed up by a threat sanction. Modern legal positivism speaks of the acceptance of law by a community rather than the command of a sovereign.

logical atomism —a philosophy defended by Bertrand Russell in his 'The Philosophy of Logical Atomism'. It held that all meaningful propositions were truth-functions of elementary or atomic propositions which, in turn, characterized metaphysically basic facts.

logical constructionism —a philosophical strategy, developed by Bertrand Russell, which treated philosophically troublesome entities (e.g. numbers, physical objects) as analysable in terms of—or 'logically constructed out of'—less troublesome entities (e.g. sets, sense data).

logical empiricism –*see* logical positivism.

logical positivism —the view of the Vienna Circle that philosophy should use modern logic (deriving from Frege and Russell), various analytical techniques and the verification principle to restrict philosophical pursuits to the

advancement of 'scientific' knowledge, thereby banishing metaphysical concerns from philosophy.

logical type —classification of logical expressions into objects, predicates, etc., depending on their logical category.

mass terms —terms such as 'water' or 'food' that stand for quantities of stuff, rather than distinct individuals.

Meinongian —view characteristic of Alexius Meinong, chiefly the view that there is a distinction between what there is (what has 'being') and what exists.

mereological sum —object that has arbitrary other objects as its parts. Defined formally as the object that overlaps exactly those other objects.

mereology —study of the part-whole relationship.

meta-ethics —while substantive ethics concerns itself with theories of right and wrong and good and bad, meta-ethics concerns itself with the more general question of what, exactly, ethical theories are theories of. Answers range from that simple, undefinable, non-natural object of thought, goodness, to nothing at all.

meta-language —a language used to talk about another, 'object-' language.

metaphysical realism —generally, the view that a particular class of entities, such as universals, exists. More recently identified as the view that truth consists of a correspondence with a mind-independent reality and that truth is 'non-epistemic', that is, is independent of our knowledge.

modal logic —that branch of logic that deals with the concepts of necessity and possibility.

modal operator —expression such as 'necessarily' or 'possibly' that expresses a modality, or mode of truth.

modal realism —the view that possible worlds and possible but non-actual entities exist. Contrasted with actualism.

naive realism —things are just as they seem to be in ordinary perceptual experience.

naming theory of meaning —the meaning of a name is the object it directly denotes or picks out.

natural kind —class of objects that share a common essence, or genuine property.

naturalism —project to reduce the notions and ontology of a field of study to those necessary for the study of the natural world, that is those of science.

naturalistic fallacy —specifically, the naturalistic fallacy refers to a logical error that Moore believed himself to have discovered in the work of those earlier moral philosophers whom he believed to have defined goodness in terms of some other, natural property, something which Moore thought could be logically ruled out by appeal to the open question argument. More generally, the naturalistic fallacy has come to refer to the questionable legitimacy of any move to base claims about what ought to be on claims about what naturally is.

natural-law theory —the view that there are principles or values which are independent of any human institution and to which any human legislation or decision must conform if it is to have the force of law

neutral monism —a metaphysical view, first expressed by William James, and later by Bertrand Russell. It viewed both minds and physical objects as

metaphysically secondary entities, holding that both should be regarded as constructions out of immediate experience—which, in turn, was viewed as the ultimate 'stuff' of reality.

nominalism —thesis that all that exists is particular, there are not general or universal entities. Also identified with the rejection of abstract entities such as sets and numbers.

norm —a standard which guides action by making it appropriate to claim that that action ought to be done. Ordinarily, at least, the acceptance of a norm involves recognizing that one thereby has a reason to conform to it

object theory —term used by Meinong for the most general study of objects, existent and not.

ontological argument —an argument for the existence of God which derives the conclusion that God exists just from the concept of God as 'that than which nothing greater can be conceived' or as the greatest possible being.

ontological commitment —relation of a theory to those objects that one asserting the theory believes to exist.

ontology —the philosophical study of existence in general, e.g. of the kinds of things that exist.

opacity, referential —a grammatical context occurring in a sentence and containing a nominal expression (a name, definite description or quantifier phrase) is said to be referentially opaque if the substitution of a co-referring expression, in the case of a name or definite description, or the exportation of a quantifier phrase, can change the truth value of the sentence. Thus, the fact that 'Jones believes that Cicero denounced Cataline' can be true and 'Jones believes Tully denounced Cataline' can be false, even though 'Cicero' and 'Tully' are co-referring nominal expressions (a fact that Jones does not know), indicates that the grammatical context following 'believe' is referentially opaque. Similarly, the fact that 'Jones seeks a unicorn' can be true even though the result of exporting the quantifier phrase, 'a unicorn', as in 'A unicorn is such that Jones seeks it', is false (because there are no unicorns) indicates that the grammatical context following 'seek' is referentially opaque.

open question argument —by means of the open question argument, Moore thought that he could prove that 'good' was undefinable. If we substitute any proposed definition, *x,* into 'but is *x* good?', the question is an open one, which shows, according to Moore, that *'x'* and 'good' can't mean the same thing.

ostensive definition —conveying the meaning or referent of a term by pointing out one of its exemplars, as in: 'That *[pointing]* is [what we count as] red.' In the later Wittgenstein ostensive definition is distinguished from what he calls ostensive teaching. In the latter case a learner is encouraged to call out the right name when a certain type of object is pointed to; but the learner has not yet mastered the use of the expression 'What is that

called?' In the former case the learner has mastered a language-game for asking what a given thing is called.

Pareto efficiency —one situation *a* Pareto-dominates another *b* if it is possible to move from *b* to *a*. making at least one party better off and no parties worse off. A situation is Pareto-efficient if no situation Pareto-dominates it. The concept is named after the late nineteenth-century social theorist Vilfredo Pareto.

phenomenalism —the philosophical view which attempts to analyse the physical world as a construction out of immediate experience or phenomena.

picture theory of meaning —the view, expressed by Ludwig Wittgenstein in *Tractates Logico-Philosophicus,* that the basic or atomic propositions of language function as pictures of basic facts, which, in turn, were viewed as arrangements of absolutely simple objects.

platonic realism —view that abstract entities, in particular, universals, exist and do not depend on concrete instances for that existence.

possibilia –merely possible individuals distinct from any actual thing.

possible world —way things might have been, either an abstract or concrete entity in different theories.

pragmatism —a school of philosophical thought, originally formulated by C.S. Peirce in the late nineteenth and early twentieth centuries, and developed in various ways by William James, John Dewey, and others. The Pragmatists agreed that every meaningful thought or proposition must have practical— and, therefore, observable—consequences in human life.

problem of evil —the problem of reconciling the existence of God with the existence of evil. The logical problem of evil is the claim that the existence of an omnipotent, omniscient, perfectly good being is logically incompatible with the existence of evil. The evidential problem of evil is the claim that the existence of evil is good evidence against the existence of God.

proper name —a word that names or denotes an individual object; Russell distinguished between ordinary proper names, such as 'Socrates' and 'Fido', which are disguised or abbreviated definite descriptions, from logically proper names, such as 'this' and 'that', which denote their object without any mediating descriptive content. Other philosophers, such as Donnellan and Kripke, have argued that ordinary proper names actually function the way that Russell thought logically proper names do.

quiddity —'suchness', qualitative individual essence.

radical interpretation —determining the conditions under which a speaker's utterance is true without relying upon previous knowledge about what the speaker believes or what language he or she speaks.

rationalism —some knowledge does not depend on the evidence of the senses. (Strict rationalism: no knowledge depends on the evidence of the senses, and genuine knowledge does exist.)

realism about something, *x* —the existence of x does not depend on the intellectual or perceptual processes of a conceiver.

rigid designator —expression that designates the same entity in every possible world. Contrasted with definite descriptions which may not be rigid.

scientific realism —thesis that the entities and properties postulated by science are real.

scientism —perjorative term for the excessive veneration or respect for science.

semantic holism —the meaning of any statement depends on the meaning of some other statement(s).

set —a group or collection of individuals itself viewed as an individual.

ship of Theseus —a legendary ship which was replaced plank by plank until it had no plank in common with its original constitution.

singular term —a proper name, definite description, singular personal pronoun, or demonstrative pronoun.

situational ethics —situational ethics is the view that no theories of ethics are possible because any action's rightness or wrongness depends entirely on the situation in which it is performed, and all situations are unique.

sortal term —a general term for a sort or kind of individual thing, e.g. 'table', 'lion' or 'number', as opposed to mass terms like 'water', or adjectives like 'blue'.

statutory law —a statute is an act of a legislature commanding or forbidding something. Unlike common law which consists of decisions of courts, statutory law consists of statutes.

substantive ethics —in the early twentieth century, this branch of philosophy concerned itself with the general question of what makes actions right or wrong. Some answers to this question proposed a single, general principle, such as 'those acts are right which produce the best consequences', while others proposed a number of such principles, such as Ross's list of *prima facie* duties. But according to the situational view of ethics espoused by Carritt, substantive ethics was, strictly speaking, impossible; there simply was no general answer to the question of what it is that makes acts right or wrong.

synthetic truth —a statement that is true in virtue of considerations other than the meanings of the constituent terms.

temporal part —an object at a moment or through an interval seen as an individual in its own right.

theodicy —the attempt to explain what justifies evil or what is the reason for evil.

token/type —a distinction between particular occurrences of a kind and the kind itself. The distinction is usually applied to linguistic entities. Thus in the sentence 'The man bit the dog' there are two tokens of the type *the;* on the other hand there are only four word types in the sentence. So if we ask how many words there are in the sentence we will get a different answer depending on whether we mean word types or word tokens.

truth-function —a given proposition, *p,* is a truth-function of the propositions which make up a certain set, *s,* if and only if the truth-value (i.e. the truth or

falsity) of *p* is completely determined by the truth-values of the propositions in *s*. Russell and Wittgenstein were attracted to the view that all of the propositions of language are truth-functions of a set of elementary propositions about elementary facts. Russell never embraced this view without reservation, but Wittgenstein defended it in the *Tractatus Logico-Philosophicus*.

utilitarianism —a kind of consequentialism, utilitarianism ties the rightness of acts to the maximization of utility; 'utility' may simply refer to pleasure, or it may include such goods as personal affection and knowledge, as in Moore's ideal version of the theory. In more current usage, however, 'utility' is usually confined to either pleasurable mental states or satisfied preferences, and so Moore's theory would now be designated as a non-utilitarian form of consequentialism.

variable, bound —in symbolic logic, a variable such as *x* or *y* that is preceded by a quantifier 'For all *x*,…' or 'For some *y*,…', as opposed to a free variable, which is not.

verification principle —a principle espoused by the members of the Vienna Circle which held that a meaningful non-logical proposition must be capable, in principle, of empirical verification. Various formulations of the principle were offered with none winning general acceptance. The principle was used to discredit traditional metaphysics.

Vienna Circle —a group of philosophers, many with scientific or mathematical training, who came together in Vienna under the leadership of Moritz Schlick during the 1920s. The group espoused the philosophy of logical positivism, which proved to be both influential and controversial for two decades both on the European continent and in the English-speaking world.

Zeno (of Elea) —a pre-Socratic Greek philosopher (born about 490 BC) who is best known for formulating what have come to be known as 'Zeno's paradoxes'. These are arguments, still objects of respectful scrutiny in the twentieth century, designed to prove that change, in the form of physical motion, is impossible. Zeno also argued that the concepts of plurality and spatial location are deeply incoherent and so have no application to reality. He believed that reality, properly understood, is an unchanging, undivided whole. As such, there are interesting parallels between Zeno's thought and that of the absolute idealists of the late nineteenth and early twentieth centuries.
